W. R. Bullard discussed the subject and he believed the most important conclusion was that single-conductor buried cable of the non-metallic armored type had better burn-off characteristics than the other types of construction tested. He also brought out that with the use of this type of cable the necessity for good burn-off characteristics might be eliminated.

W. A. Del Mar discussed this subject explaining that there were many types of non-metallic trench cable being manufactured and purchased on various kinds of specifications, some of which merely describe one type or another, while others are based only on performance tests. He expressed the need of coordination in this field and advocated a course of procedure whereby the devising of tests would be a joint effort of the operating and manufacturing engineers. The designs of cables to meet these tests should be left to the cable maker.

B. M. Jones discussed this subject from the economic standpoint of planning an a-c. low-voltage network with provisions for sufficient spare capacity to burn clear a fault of the most severe type in the weakest spot with any one particular supply feeder out of service.

Arcs in Low-Voltage A-C. Networks

W. R. Bullard in his discussion of this subject explained that his experience agreed with the statement in the paper presented that pre-carbonization of cable insulation destroyed its arc-extinguishing features.

W. G. Dow discussed the differences in the values of the arc-reignition characteristics brought out by the two papers and set forth reasons for the difference in the results.

T. E. Browne, Jr., discussed "The Reignition of Metallic A-C. Arcs in Air." He commented on the point that the oscillograms were the first obtained that had shown directly on a time axis just what occurs to the current and voltage of a short a-c. arc during the elusive-current zero period.

A Primary Network

E. R. Hendrickson in his discussion of the subject inquired if the primary network would represent the correct solution for service to a territory of low- or medium-load density, where because of the importance of continuity of service or future load growth, a secondary network would be required in the future.

W. R. Bullard in his discussion of the subject advocated using a type of system which would eliminate the intermediate transformation and supply the distribution transformers directly with generating station or transmission terminal substation voltage. Such a system would have the advantages of simplicity and greater economy.

H. Richter discussed the paper from the standpoint of developments made in the apparatus employed. The two 1,500-kva. transformers are the largest subway-type transformers thus far produced and the regulators so far as is known are the first of the subway type built in this country.

A. H. Sweetnam discussed the subject and the planning which lead up to the adaption of a 4,000-volt network system to supply a certain area. Estimates were made of the relative cost of supplying this area by means of a 4,000-volt network or the construction of a new substation. The economic study was extended to cover ultimate load requirements and it was found to favor the 4,000-volt network system with a saving of 20 per cent capital investment.

In contrast to the foregoing paragraph H. L. Wallau discussed a comparative estimate made five or six years ago which indicated a relative investment of 100 per cent for the radial type *vs.* from 106 to 118 per cent for the networked type.

G. M. Miller in his discussion of this subject explained that the primary network is a long step forward in a scheme to reduce investment and operating costs, to provide improved service, and give greater flexibility in handling increases in load.

The Philadelphia A-C. Network System

H. Richter discussed this system and drew attention to the length of time required for transformer secondary fuses to clear primary faults. He believed that the automatic protector would answer this requirement much better than the transformer secondary fuses.

System Grounding Problems

In the session devoted to grounding, relaying, and transmission problems five papers were presented. One of these was in reality a subcommittee report covering grounding practises.

System Grounding Problems

E. C. Stone capably analyzed the second report of the subject committee on grounding. A comparison with the first report of eight years ago indicated no radical changes but some interesting trends, one of which was toward the solidly-grounded system.

H. M. Trueblood discussed "Reactance of Transmission Lines with Ground Return" and analyzed the terms in Carson's expression on the hypothesis that the earth is of infinite conductivity.

P. A. Jeanne discussed this paper and expressed his beliefs that the method of developing the formulas for the zero sequence impedance as outlined in the appendix is preferable to the method given in the main body of the paper because it involved only the use of complete ground return circuit impedances.

C. L. Gilkeson presented a discussoin prepared by F. J. Grueter on the same paper. One of the points discussed was the simplifying assumption made in the development of the method of calculating zero-sequence impedance that uniform current exists along the length of the ground wire. This condition holds only when the ground wire is terminated in impedances to ground which are small compared to the resistance to ground of the tower footings. G. Waschick in his discussion of this paper also referred to the same point.

J. E. Clem discussed "Power System Voltages and Currents under Fault Conditions." He suggested a classification based on overvoltages for grounding systems, or circuits, as follows: solidly-grounded, effectively-grounded, non-effectively-grounded, and isolated. For this classification certain auxiliary terms were defined.

H. W. Bibber's discussion of this paper was read by J. E. Clem. For those who wished to go further into the subject in a more detailed and mathematical manner he suggested an article in the May 10, 1930, *Revue Générale d'Electricité* by J. Fallou.

C. A. Powel read Mabel Macferran's discussion on "Simultaneous Faults in Three-Phase Systems," which clearly pointed out the practical value of the paper. J. E. Clem read a discussion prepared by H. W. Bibber on this paper. It indicated that Miss Clarke's methods of calculating simultaneous faults on grounded systems could be extended to include the determination of currents and voltages in isolated neutral systems.

Closing Session Discussion

The closing session was devoted to "selected subjects" concerning industrial power applications and communication developments.

R. R. Johnson discussed "A Modern Electrified Dairy Plant" and explained that the change-over of which the authors spoke was conceived approximately six years ago. Another interesting point cited was that only five unarranged outages, totaling one hour and three minutes, have occurred since the substation was installed in 1925.

One of the interesting points described by A. T. Ruttencutter in connection with his discussion of the paper was the application of the "Electropure" process of pasteurizing milk. B. W. Faber also discussed this paper and inquired if the pasteurizing of milk increased the quality of the milk.

J. L. Woodbridge discussed "Power Supply for Telephone Systems" and described the developments in the design and application of the storage battery for this service. I. R. Smith in his discussion of this paper described and illustrated with lantern slides the development of the dry disk copper oxide or Rectox rectifiers for the various applications described in the paper. Efficiency and life test performance curves for these units were also shown.

K. C. White discussed "Power Supply for Telephone Systems." He explained that the Pennsylvania Railroad had applied several of the power plants described in the paper to a rather extensive dial telephone system in the Western Pennsylvania and the Eastern Ohio areas. These automatic power plants have greatly reduced the maintenance required resulting in a smaller operating personnel, better voltage regulation, longer battery life, and practically fool-proof operation. R. L. Dunlap in connection with the discussion of this paper described the advantages accruing from the installation of some of the 72 automatic power plants installed in the Pittsburgh territory.

C. S. Alt discussed this paper as well as "Telegraph Power Plants." He described the special requirements for emergency engine sets for this particular service, such as the ease of starting, quietness, freedom from vibration, and safety features.

In connection with discussion on "Telegraph Power Plants," G. H. Kendricks described interestingly some of the early power plants of the Western Union Service in Pittsburgh and told of some of the difficulties encountered.

OVERSEAS TELEPHONE SERVICE

J. P. Scott discussed this subject and inquired as to the total per cent of lost time due to all causes; also as to how often magnetic storms were usually experienced.

W. C. Hecht asked how the practical operating hours were affected by the differences in time of day at the terminals.

N. S. Hoff inquired as to the steps involved and the length of time required from the conception of a radio circuit to the establishment of actual service.

In other discussion on this paper W. L. Schafer referred to the gains obtained by the use of the directive antenna arrays at the transmitter and receiver, and inquired as to the possibilities of further substantial gains by such means.

Other equally interesting and pertinent questions were asked during the discussion of this paper which was presented by F. A. Cowan.

Engineers' Economic Conference To Be Held by Stevens Institute

AN ECONOMIC conference for engineers will be held from Aug. 30 through Labor Day, Sept. 7, 1931, at the engineering camp of Stevens Institute of Technology near Johnsonburg, Warren County, New Jersey. The engineering alumni of Columbia University and the alumni of Stevens, under whose joint auspices the conference will be held, will welcome to the camp graduates of other colleges and younger members of the national engineering societies. The hours for lectures, conferences, and round-table discussions by some of the leading economists and engineers of the country are to be scheduled so as to permit the men in camp to make full use of the camp's unusually good facilities for land and water sports.

The serious part of each day's program will have two main elements: in the morning the lectures and discussions will deal with "The Dollar Factor in Engineering," or "Technique in Calculations Involving Money;" at the open forum and round-table discussions in the evening, elements in depression, and seasonal and cyclical fluctuations will be considered. The Carnegie Corporation, on the recommendation of the American Association for Adult Education, has endorsed the project through a grant of $1,500.

THE ECONOMIC FACTOR IN ENGINEERING

Lectures and conferences scheduled for the morning hours will be under the direction of William Duane Ennis, head of Stevens' department of economics of engineering who will be assisted by members of the Stevens and Columbia faculties. In his outline of the subjects to be dealt with Prof. Ennis remarks that:

> Every engineer knows that a point is reached in his problem where commercial factors, so-called, must receive consideration. Too often from this point the problem is relegated to another than the engineer; perhaps to a lawyer, perhaps to a "business man." No sufficient reason for this exists. There is a body of principles underlying the evaluation of commercial factors just as there is a mass of doctrine back of engineering factors. In the setting of an interest rate, no less than in the determining of a stress, there is a mass of facts and coordinations, not scientific, perhaps, but nevertheless organized. The course proposed for the coming summer aims to develop some of the principles which are fundamental in applying money factors to engineering problems.

THE BUSINESS CYCLE

In addition to the morning series of lectures and seminars on the "money factor" in engineering, the economic conference is planned to include eight or nine evening lectures and round-table discussions on the business cycle. Four major questions of business depression are proposed for consideration:

1. What is the most significant statistical description of what has happened since the fall of 1929?
2. What statistical approach looks most hopeful for forecasting or for starting a public works program?
3. What is the most significant explanation of what has happened?
4. What to do about it.

The first two questions, bringing out a description of a period of depression, will be discussed by leading financial and government analysts. The third will be submitted to investigators in theoretical economics associated with university faculties and research staffs of private corporations. Under the fourth topic, emergency relief, industrial stabilization, unemployment insurance, and long-range planning will be debated by men who have been actively engaged in solving such problems for industrial organizations and civic committees.

Engineers interested in attending this conference should communicate promptly with Stevens Institute of Technology, Hoboken, New Jersey. Accommodations at the camp are limited.

Mining Engineers Report Upon Russian Living Conditions

AMERICAN engineers considering employment in the United States of Soviet Russia are face to face with a stern situation according to an exhaustive report presented to and approved by the board of directors of the American Institute of Mining and Metallurgical Engineers March 20, 1931. The investigation was authorized by the A. I. M. E. board of directors Nov. 21, 1930 and the report was published on pp. 207-8 of *Mining and Metallurgy* for April 1931. The following excerpts are taken from the published report:

General Observations

"The government in Russia is undertaking an experiment completely at variance with accepted American procedure by methods wholly contrary to American ideals. The country has a form of government comparable with the most drastic type of martial law as Americans understand that term. Industrial conscription forces every individual into service.

"The Soviet Government is seeking to industrialize in the next few years a backward country under a program which, if completed, will place Russian industrial production on a plane with or above the present production of the United States in the major basic industries—a plane which has been attained only by decades of orderly progress. The first step of their program is the Five-Year Plan now in course of execution. The Soviet Government proposes to accomplish its aims not through private initiative, but through direct government action. . . .

"The success of the plan is absolutely essential for the continuation of the Soviet regime and nothing—not even human life—is a barrier to their efforts to force the plan to success. A wholly artificial condition of living has been created. Individual initiative and the reward for effort are completely submerged under despotic discipline and drastic penalties. . . .

Living Conditions

"Food, generally speaking, is scarce; some, of very poor quality. It is extremely expensive unless bought at government stores with a government food card. While conditions are not uniform throughout Russia, in Moscow and Leningrad long lines of people are obliged to stand in front of these stores waiting to enter. . . .

"Individuals proceeding to Russia at this time must be prepared to assume the role of pioneers, *i. e.*, stand hardships and discomforts not met with in other countries. Such conditions can be tolerated by some, but others will find them unbearable. They may find themselves impaired in health, become discouraged and unhappy, resulting in regret for their decision to leave a peaceful civilized country despite the opportunity for more pay than now attainable at home. Without question, an engineer should not take children into Russia. Most people familiar with conditions there strongly advise against the taking of wives, unless they be strong, healthy, robust individuals, accustomed to discomforts and inclined to enjoy overcoming difficulties and the fighting of adverse conditions.

"It would be well before accepting employment to confer with several engineers who have worked in Russia under comparable conditions.

Legal Status and Personal Safety

"An individual accepting employment under the Soviets must appreciate that he is working for an autocratic government. The United States has no diplomatic relations with Russia and there is no United States ambassador or consul to whom he can appeal if he feels himself wronged.

"Adequate reasons may develop for the breaking of a contract, but still the government has the arbitrary power to take away passport and food card, and/or prevent the employee from leaving the country. In such case great difficulty may be experienced in subsisting. The engineer may be fined or forced to do menial work in punishment for alleged breaking of his contract.

"Up to the present foreigners have been safe in Russia, but will this continue to be the case? Fear is entertained that if the five-year plan should not eventuate as represented to the people, or if some plant or installation should fail to deliver anticipated results, the Soviets will seek a "scapegoat." If so, who would be more suited to that role than the foreign engineers in charge of that particular piece of work? Many people have been executed or imprisoned as "scapegoats." So far as we know, the victims thus far have been Russians; but should desperate conditions arise, may not summary treatment be extended to the foreign elements? . . .

"What would be the position of a member of the profession upon return to the United States? . . . Is the experience to be gained in Russia apt to be useful? From numerous directions we hear of a lack of organization, of changing of plans on the whim of some committee, interruption of operations because some official considers another piece of work of more importance. The engineer in charge cannot on his own authority discharge or dispense with the services of his subordinates. It is doubtful if work carried on under such conditions provides experience an American engineer can capitalize upon his return home, and it may even depreciate his effectiveness as an executive.

Recommendations Concerning Service Contracts

"So far we have only enumerated some of the conditions in Russia that suggest points to be considered (by an engineer) when deciding to accept employment in that country. *If he decides that his particular situation is such that he must accept Russian work regardless of the known unfavorable conditions*, then he should if possible give preference to employment with some large American contractor or engineering firm, rather than attempt an individual contract with the U. S. S. R. . . .

"While the matter of performance of an employment contract by the Soviets is a matter of faith, on account of the impossibility of bringing any dispute before an American court, still as far as we know they have thus far shown a disposition to live up to the *letter of the contract*. This being so, it becomes important that the contract terms should embrace every possible contingency. No dependence whatever should be placed on verbal statements or assurances. It has been found repeatedly that assurances made here have no force whatever when the employee arrives in Russia.

"Whether going as an individual or as a member of a group, one should see that the following points, among others, are provided for:

"(a) Adequate provision for first-class transportation and expenses from America to place of employment *and return*.

"(b) . . . He should insist on receiving as large a portion as possible, certainly not less than 50 per cent of his remuneration, in dollars to be deposited or paid as directed in the United States. It must be remembered that foreign money can be brought out of Russia only to the extent to which it was taken in, less the amount the authorities decide he should have spent while in Russia. After residing in Russia for a certain length of time, no foreign money can be taken out. While a certain amount in Russian currency can be sent out, it has only a greatly depreciated value in foreign countries.

"(c) . . . Visitors to Russia are required to spend a certain minimum per day and the engineer should inform himself to what extent these regulations apply in his case.

"(d) A non-resident citizen is subject to our Federal income tax, but should be free from taxation by the Soviet Government on amounts deposited in this country to the citizen's credit. A definite understanding should be had as to the amount of taxes on salaries paid in Russia, as well as on all other taxes.

"(e) Provision of living quarters, domestic servants, water, heating, light, cooking and sanitary arrangements, either free of charge or at a definite price.

"(f) Fuel for heating and cooking and price thereof.

"(g) Supply of food and privilege of purchasing food, clothing and other supplies at commissaries established for foreign diplomats and engineers.

"(h) Privilege in regard to the taking in and importing into Russia later of foodstuffs, clothing, toilet articles, etc., free of duty coupled with *guarantee of arrival.*

"(i) Outlining of duties and responsibilities of service to be renderd.

"(j) The conditions under which employees are privileged to resign with safe conduct and expenses back to the United States, etc.

"(k) Discontinuance at one job not to give Soviet the privilege of transference to another.

"(l) Various Soviet industrial organizations, operating through the Amtorg Trading Corporation in New York, engage American engineers and technicians to work in Russia. As there are no relations between the government of the United States and that of the Soviet Union, the signature of the Amtorg for itself as an American corporation should always be obtained to any contract.

"The foregoing observations should be regarded only in the light of general suggestions. They are intended to call attention to the unusual circumstances surrounding the Russian situation; each case will require more individual treatment than is possible in a general report. *—Respectfully submitted, Henry Krumb, chairman; Lucius W. Mayer, J. V. W. Reynders, Edgar Rickard.*"

Electric Steam Generator For Sterlization Processes

Packed heat from a new type of electric steam generator displaces steam from high-pressure mains, it is declared by Howard Bidwell and Linus H. Jones of the Massachusetts Agricultural Experiment Station, Amherst, in a report to the American Chemical Society.

"The new electric generator," the report says, "is applicable for use with hospital sterilizers, pressure-cooking retorts, or in any industrial process where a large quantity of steam is necessary for a short period of time.

"There are many processes in the scientific and industrial fields that require large amounts of steam for periods of short duration. High-pressure steam is expensive and its cost is becoming so excessive that this method is almost prohibitive during the non-heating months. There is also a labor cost if the law of the state demands a licensed operator.

"This generator has a reservoir in which heat is packed and stored. The result is that within thirty seconds from the time of closing the autoclave the required sterilizing pressure is registered. This may be obtained at any time by throwing a switch and opening two valves.

"The principle employed in the action of this boiler is that law of physics which governs the varying boiling points of water under different pressures. Depending upon the water capacity of the generator, irrespective of the steam space, any desired volume of steam at a lower pressure can instantly be made available by suddenly relieving the pressure on the generator.

"The use of fuel or electric steam generators that build up a sterilizing temperature in a retort decreases the working efficiency of the autoclave and its attendant. Time consumed in heating and cooling a large volume of water means time lost. The most satisfactory method is that which gives a sterilizing temperature immediately and allows one to stop the supply of heat as soon as the charge has been sterilized. The new electric steam generator gives all that can be desired as a source of steam and heat."

Saluda Completed To 162,500 Kva. Capacity

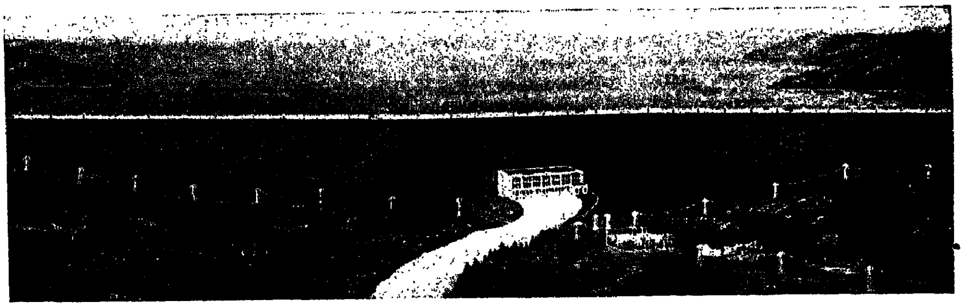
Completion of the Saluda development of the Lexington Water Power Company, subsidiary of the Associated Gas & Electric Company, injects another important factor into the industrial power situation of the southeastern states. The installation is on the Saluda River nine miles above its junction with the Broad River at Columbia, S. C., where a 7,838-ft. earth dam with its crest at El. 372,208 ft. above the river bed forms the Lake Murray reservoir which is 41 mi. long and 14 mi. wide at its widest point. With an area of 78 sq. mi. this reservoir has a capacity of some 2,340,000 acre ft., which is said to represent 200 million kw-hr. at normal rates of withdrawal under average conditions. At its base at the power house the dam is 998 ft. thick; 1,150 ft. thick at its base at its maximum point, and contains 11,000,000 cu. yd. of earth fill.

The present installation which represents two-thirds of the expected ultimate plant capacity includes four 40,625-kva., 0.8-power-factor, 13.8-kv., three-phase, 60-cycle, 138.5-rev. per min. vertical generators direct-connected to 55,650-hp. Francis turbines, designed to develop full rated horsepower at 180-ft. head with full gate opening. The generators are of the single-bearing overhung-rotor type, having a thrust and a steady bearing in the same oil pot beneath the rotor.

At the present time, surge tanks are installed only for units Nos. 1 and 3, which units it is intended will do the regulating for the plant with high-speed governing equipment, whereas units Nos. 2 and 4 are expected to run practically at constant load with slow-speed governing.

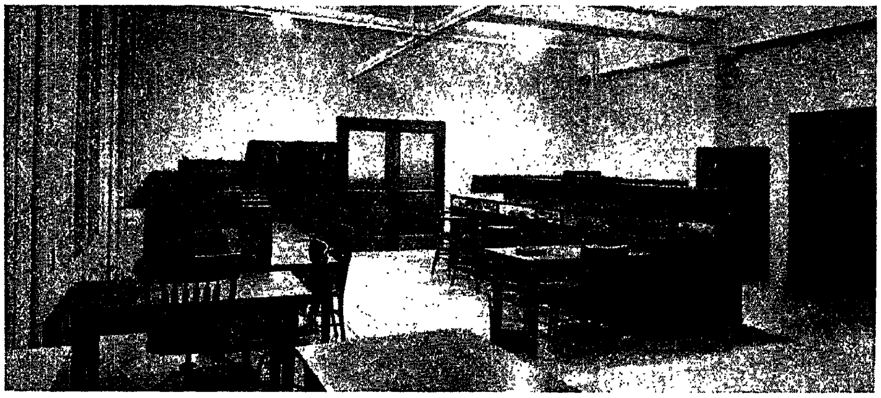
The plant output is stepped up to 125.6 kv. through 40,000 kva. outdoor transformer banks at the plant, and carried approximately a thousand feet down the stream to the high-voltage switching substation whence it is distributed throughout the interconnected Associated Gas & Electric system.

Engineers for the project were Murray & Flood, and W. S. Barstow & Company, Inc.; Albert S. Crane was consulting engineer. Designs for the dam, conduits, intakes, surge tanks and spillway were made by the J. G. White Engineering Corporation, and the designs for the power house and substation were worked out by W. S. Barstow & Company, Inc. The dam, conduits, and intakes were built by the Arundel Corporation, and the power house, spillway, and substation, by W. S. Barstow & Company, Inc. The steel-pipe conduits were furnished by the Reeves Brothers Company; the penstocks and surge tanks by the Chicago Bridge & Iron Company; the intake gates by Phillips & Davies, Inc.; the turbines, butterfly valves and Radial gates by the S. Morgan Smith Company; the turbine governors were built by the Woodward Governor Company; the generators by Westinghouse Electric & Manufacturing Company; and the transformers by General Electric Company



Artists sketch of Saluda development in South Carolina

Special Laboratory Lighting at Penn State



AN UNIQUE and important improvement in laboratory lighting was demonstrated recently in the completion of a new building at Pennsylvania State College. In this, lighting is provided by direct prismatic glass globes, the lower half of each being color-correcting, blending well with daylight and entirely satisfactory for night use. Sufficient unmodified light passes through the upper half of the globe to illumine the ceiling, and overbalance the unfavorable appearance at night of daylight lamp equipment, at the same time in no way interfering with the identification of colors in specimens being studied. With this type of fixture 300-watt lamps with approximately 11-ft. centers produce an intensity of from 18 to 20 foot-candles on the tables. . . . (Contributed by Prof. D. L. Markel, State College, Pa., through the A. I. E. E. committee on the production and application of light.)

N. E. L. A. Annual Convention June 8-12

The Atlantic City Auditorium and Convention Hall will be the headquarters of the fifty-fourth annual gathering of the National Electric Light Association.

The convention will open officially June 8, although the registration desk will be active June 6 and 7; the exhibition Monday, June 8, at 9 a. m., continuing daily throughout the convention dates. Special features of the convention's program will be a "national employee speaking contest" on Monday with award of the prize on Thursday. On Tuesday, June 9, there will be a "seaview day" for the ladies. A diversive program fitted to this special season but in no way neglecting technical values will be offered by this convention.

Purdue University Receives Airport Site

In proof of his faith in the future of aeronautics and as another evidence of his foresight for Purdue University, David E. Ross, president of the board of trustees of the university, has purchased and deeded to the university three tracts of land totaling 157 acres, to be developed as a Purdue airport. The tract which is level and free of trees lies half-mile southwest of the campus and adjoins Edgewood farm owned and operated by the university. This if it were found desirable to do so at a later date could be used as part of the landing field giving a combined tract of 317 acres on level land.

The area purchased by Mr. Ross has been officially inspected by representatives of the U. S. Department of Commerce and received high approval for aircraft purposes. Adequate markings have been placed for the new airport and the field has been included in the new airport map of this region prepared by the Department of Commerce.

Triennial Montefiore Prize Award Now Open

Constituting interest on 150,000 Belgian francs, distributed triennially in international competition for the best original work presented on scientific advancement and progress in technical application of electricity in every field, the Montefiore prize award now is open again to candidates.

To be eligible an achievement must have been made public at some time during the three years immediately preceding the period of award. Papers either signed or anonymous are acceptble in manuscript or reprint form; they must, however, have been edited in either French or English; also, all manuscripts must be typewritten.

By a four-fifths vote of the board of examiners composed of five Belgian and five other electrical engineers, one-third of the amount available may be designated as an unsecured loan to a person whose work does not fall completely within the ritual of the governing program but which demonstrates a new thought in connection with development of importance in the sphere of electricity.

Can You Supply These Transactions?

The engineering department of the University of Tennessee, through its trustee Paul J. Kruesi, is making an appeal for the following back volumes of A. I. E. E. Transactions:

1884-87 (inclusive of vols. I, II, III and IV; vols. I and III desired if available in separate unbound form)
1887-88 (vol. V)
1888-89 (vol. VI)

Mr. Kruesi will be grateful to anyone willing to spare these copies to complete the University's library records. Address Miss Laura Kersey, Librarian, Engineering Library, University of Tennessee, Knoxville, Tenn.

Outdoor Generators For New Bagnell Dam

First shipments on an order for waterwheel generators to be used at the new Bagnell Dam on the Osage River, Missouri, are being made from the Westinghouse Electric and Manufacturing Company, East Pittsburgh, to the Union Electric Light and Power Company, St. Louis, Mo. The six generators are of the so-called outdoor type and will be built into the foundation of the spillway. Instead of the usual power house, the units will simply be covered with large cast iron lids which may be removed as desired by a large traveling crane. Only the controls will be housed inside of rooms built into the wall of the dam.

In operation the generators will become a part of the 201,000-hp. development on the Osage, the Bagnell Dam being a structure 148 ft. high from bedrock to highway and forming a reservoir 129 mi. long with an area of 95 sq. mi. and 1,300 mi. of shoreline. In the development of this reservoir it has been found necessary to move an entire town four miles to higher ground. The Bagnell Dam is located 130 mi. southwest of St. Louis.

Engineering Foundation

Education Research Committee Established

Engineering education during the past decade has received much serious attention from engineers, educators, industrialists, philanthropic foundations, and various government agencies. Through the Society for Promotion of Engineering Education, Engineering societies have cooperated with engineering colleges and because of the interest expressed by its founder societies and the need for help in prosecuting the work which the Education society has had in hand, the Engineering Foundation has devoted much energy to the subject. Encouraged by discussion at its recent meetings and conferences which were attended by many men prominent in education, industry, and engineering, and advised by a small group of educational research men, the Foundation established an education research committee:

Harvey N. Davis (chairman), president of Stevens Institute of Technology; A. S. M. E.

Walter F. Whittemore, Hotel Woodstock, New York; A. S. C. E.

William B. Plank, Lafayette College; A. I. M. M. E.

Harold B. Smith, Worcester Polytechnic Institute; A. I. E. E.

Robert I. Rees, assistant vice-president American Telephone and Telegraph Company; Society for Promotion of Engineering Education.

Alfred H. White, professor of chemical engineering, University of Michigan; A. I. C. E.

Alexander R. Stevenson, Jr., General Electric Company, Schenectady, New York; The Engineering Foundation.

This committee was charged with ascertaining the attitude of the engineering societies toward a project to comprise:

(a) Fundamental research in engineering education.

(b) Vocational guidance, especially for youths in preparatory schools, including booklets giving information about engineering.

(c) Empirical investigations of objective tests and comprehensive examinations.

In preparation for outlining a project of reasonable dimensions the committee is making a preliminary study of:

(1) Placement of graduates of secondary schools (and other young persons) in engineering colleges.

(2) Objective tests, for various purposes.

(3) Placement of engineering college graduates in industry and business.

(4) Correction of the maladjustment of certain students and graduates to their social and other environments.

(5) What Engineering Foundation can do to be to engineering what the Chemical Foundation has been and is to chemistry, in extending the public's knowledge and appreciation of engineers and their work.

Standards

I. E. C. Announces Revision of Electrical Machinery Rules

Final approval of the I. E. C. *Publication No. 34* containing the revised I. E. C. rules for electrical machinery was given by the U. S. National Committee of the International Electrotechnical Committee at a meeting held February 6, 1931. In its present form this publication was drawn up at the I. E. C. plenary meeting held at Oslo in July 1930; it represents, however, the culmination of ten years of continuous effort, during which time it has been the subject of debate at seven formal international I. E. C. meetings.

The revised publication represents the agreement of national committees of the I. E. C. in more than a dozen countries, and constitutes an international consensus of opinion concerning the more usual requirements of electrical machinery standards similar to those now a part of the various national standards, such as the A. I. E. E. Standards in the United States, the B. E. S. A. Standards in Great Britain, and the V. D. E. in Germany. It covers all sizes of transformers and rotating electrical machines except traction motors, and supersedes the 1920 edition. Other I. E. C. Standards publications include the following:

Number	Title	Price
27.	International Symbols (first part) Letter Symbols	$0.50
28.	International Standard of Resistance for Copper	0.50
34.	**I. E. C. Rules for Electrical Machinery**	**1.00**
35.	International Symbols (second part) Graphical Symbols for Heavy-Current Systems	1.00
37.	Standard Dimensions of Bayonet Lamp Sockets and Caps	0.25
38.	I. E. C. Standard Voltages	0.25
39.	International Rules for Traction Motors	0.25
41.	I. E. C. Publication on the Testing of Hydraulic Turbines	0.50
43.	I. E. C. Recommendations for Alternating Current Watt-Hour Meters	0.50
44.	I. E. C. Recommendations for Instrument Transformers	0.50

Copies of any of these publications may be obtained from the secretary of the U. S. National Committee, I. E. C., 33 West 39th Street, New York, N. Y. They may be obtained also from the central office of the commission by addressing Mr. C. le Maistre, 28 Victoria Street, London, S. W. 1, England. In ordering this literature it is essential that the request be accompanied by the proper remittance.

How to Obtain the New Standards Yearbook

The 1931 volume of the Standards Yearbook compiled by the National Bureau of Standards and containing authentic and carefully investigated information on (I) Standardization in transport (in symposium form); (II) International standardizing agencies; (III) National standardizing agencies; (IV) Federal standardizing agencies; (V) National Bureau of Standards; (VI) Municipal, county, and state purchasing agencies; (VII) General standardizing agencies; (VIII) Standardizing activities of technical societies and trade associations; (IX) Bibliography on standardization; and (X) a complete Index, is now off the press. In the transport division (I) falls such facts as relate to research and experiment in aviation, automotive, and highway development and safety; railroads, pipe lines, elevators, marine navigation, speech and power transmission, and other important government activities. The volume also reports an annual bibliography on standardization prepared by the Library of Congress. The price of the book for domestic distribution is $1.00; it is obtained by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C.

New Standards Data.—A new compilation of data entitled, "Measurement Units and Standards," has been issued recently by the American Institute of Weights and Measures; a copy of this book may be obtained gratis by applying to the Institute, William E. Bullock, secretary, 33 Rector Street, New York. In addition to the data on units and standards, the book contains an article recommending *timex* and *spacex* as names for the Einstein specialization of basic time and space. It also contains a description of the difference between a *unit* and a *standard*, prompted by the lack of unanimity existing in reference publications.

Personal

High British Award to Francis Hodgkinson

Francis Hodgkinson (Asso. '02), consulting mechanical engineer for Westinghouse Electric & Manufacturing Company and well known in marine circles for his many contributions to efficiency by improvement of steam-driven machinery and electrical apparatus, has received the Willans Premium, a high British engineering honor awarded by the Institution of Mechanical Engineering, London. The award was given for the best paper published in the *Proceedings* of the Institution from 1925 to 1930 inclusive, and is being forwarded to Mr. Hodgkinson in the form of a gold medal. His prize-winning paper was entitled "Journal Bearing Practise."

The Willans Premium which may be awarded in the form of medals, books, or cash as the council may determine, was established 1897 to perpetuate the name of Peter William Willans for services rendered engineering and electrical science. It is awarded alternately by the Institution of Mechanical Engineers and the Institution of Electrical Engineers, for the best original paper coming before either institution, and dealing with—utilization and transformation of energy treated especially from the point of view of efficiency and economy. The award is made triennially, but may be carried over according to the judgment of the governing board.

FRANCIS HODGKINSON

Mr. Hodgkinson was associated with the late Sir Charles A. Parsons in early experiments and turbine developments in England. Following a term in the Chilean Navy and engineering work in Peru, he became associated with the Westinghouse company in 1896 when George Westinghouse was introducing the Parsons turbine in this country. When the South Philadelphia works were established in 1916, Mr. Hodgkinson was chosen chief engineer and in 1926 was advanced to the office of consulting mechanical engineer for all branches of the Westinghouse company.

Dr. Luckiesh Honored by Optometry Foundation

For his contributions in "constructive ideas for optometric research" Doctor M. Luckiesh (Mem. '15) has been awarded a fellowship in the Distinguished Service Foundation of Optometry, Cleveland, Ohio. The Foundation contends that through his many papers and lectures presented before the Optometric Association, Doctor Luckiesh has promulgated the understanding by the optometric profession of the part lighting plays in the conservation of eyesight.

M. LUCKIESH

The Distinguished Service Foundation which was established in Boston, March 1927, has as its purpose effort "to provide an agency for encouraging research, inventive and experimental work by practising optometrists, physiologists, physicists, illuminating engineers and others, to award gold medals and fellowships for such research and scientific attainments, and to encourage and aid men and women of marked proficiency to discover knowledge which that will benefit human vision."

James W. Welsh, (Fel. '14) who in the fall of 1929 became identified with the Cleveland Railway Company as assistant to its president, has resigned to come to New York to establish his own organization of traffic consultants. After seven years as executive secretary of the American Electric Railway Association Mr. Welsh went to Cleveland a nationally recognized authority on electrical engineering and traffic problems, and a specialist in traffic engineering. He has devoted his time to studies of proposed coordination of rapid transit and surface lines, and the application of zone-fare principles to the Cleveland Railway system. By the president of that system he is accredited with having made possible the speeding up of surface lines and the realization of substantial operating economies. Mr. Welsh contends that the continued growth and development of our cities depends as much upon the efficient use of existing transportation facilities as upon the provision of additional ones; that we should be sure we are getting 100 per cent use from these facilities before assuming additional burdens. In 1924 he was a member of a special committee which studied European transporation conditions for the American operators of electric railways.

O. S. Peters (Assoc. '11) for many years conspicuous by his achievements as an inventor of electrical devices, has been made the recipient of the John Scott bronze medal for the invention of a telemeter for recording strains and pressures. The invention may be said to be the outgrowth of ten years' effort in technical research work with the Bureau of Standards. The instrument has been in commercial use for a number of years and has proved its value in an extended field of utility. Mr. Peters, after the completion of his technical studies at Montana State college, returned the following year as instructor in electrical engineering. His term of service with the Bureau of Standards was from 1910 to 1918, as assistant physicist.

A. W. Leonard, (Mem. '29) connected with Stone & Webster interests for the past 36 years, and president of the Puget Sound Power & Light Company, Seattle, retired from the presidency April 1 to assume the chairmanship of the board of directors of the parent organization, the Engineers Public Service Company, with offices in New York City. His predecessor in this capacity was Charles W. Kellogg, (Mem. '23), who has managed the Stone & Webster properties for an extended number of years, and who is now retiring after a most successful record.

B. A. Behrend (Fel. '12) of Wellesley Hills, Mass., has just had the honorary degree of doctor of engineering conferred upon him by the University of Darmstadt "for meritorious work in the construction of induction machines." Mr. Behrend has gained prominence in the American engineering world both by the assistance he has rendered the Institute in the past with his work on its committees and by his various other worthy engineering affiliations. He is at present carrying on a successful consulting engineering practise of his own at Wellesley Hills.

Donald M. Simmons (Fel. '28) chief consulting engineer of the General Cable Corporation, New York City, has been elected president of the Insulated Power Cable Engineers' Association. Other officers are T. F. Peterson, cable engineer of the American Steel & Wire Company, New York, vice-president, and R.J. Wiseman, (Fel. '27) chief engineer of the Okonite Company, Passaic, N. J., secretary and treasurer. The retiring officers are G. M. Haskell, president; W. A. DelMar, vice-president; and H. G. Burd, secretary and treasurer.

L. J. Bourke (Assoc. '23) for the past several years assistant to William H. McGrath (Mem. '20), vice-president of the Puget Sound Power & Light Company, Seattle, received appointment effective March 1, 1931, as manager of the company's southern district at Chehalis, Washington. Homer R. Chitty, Jr. (Assoc. '28), who has held office as manager of that district for some time past has been transferred to Tacoma in charge of the southwestern district of the company.

L. A. S. Wood (Mem. '24) manager of exterior lighting section, Westinghouse Electric & Manufacturing Company, Cleveland, Ohio, has been given complete charge of a new division centering all lighting activities of the company into a movement of coordination at the Cleveland works. This concentration represents the culmination of a nucleus plan made when the Westinghouse lighting activities first were established in Cleveland.

Clarence A. Mayo (Assoc. '13) electrical engineer of the Malden Eectric Company, Malden, Massachusetts, recently became assistant manager of the Eastern Massachusetts Electric Company. His headquarters will be in Salem. Mr. Mayo is a past chairman of the Electric Lines Club of New England and for two years chairman of the engineering section of the New England division of the N. E. L. A.

K. C. Christiansen (Mem. '21) for over ten years has been affiliated with the Electric Bond & Share Company and its subsidiary the Phoenix Utility Co.; now he has engaged with the Safe Harbor Water Power Corporation, Lexington Building, Baltimore, Md.

John Dibblee (Mem. '26) general superintendent of the Hydro-Electric Power Commission, the Niagara district, has been assigned to the recently created position of assistant to Henry C. Don Carlos (Fel. '18) the operating engineer of the provincial system.

John H. Muggli (Mem. '31) has been transferred from the Shell Oil Company's Martinez Refinery to the home office at San Francisco, where he will continue his capacity of electrical engineer.

Obituary

Robert J. Scott, (Fel. '13) professor emeritus of the University of New Zealand, Horomanga Island, Port Levy, Banks Peninsula, New Zealand, and for many years local honorary secretary of the Institute for New Zealand, passed away November 8, 1930.

He was born at Plymouth, England, September 14, 1861, the son of Rear Admiral Scott and a cousin of Captain Scott the South Polar explorer. He attended the Abbey School, Beckenham, King's College, London, and the Royal School of Mines, where his course included electrical engineering and management. Supplementing this by private tutelage in mechanical drawing and civil engineering under General H. Y. D. Scott, F. A. S., C. B., Director General of Works, England, thereafter he was employed under his father, Rear Admiral Scott, R. N., as superintendent of naval gun carriages at Woolwich Arsenal and at Chatham. In 1881, after extensive railway experience in England, he joined the New Zealand railway service, advancing from the position of locomotive draftsman to manager of the Addington works, designer for the locomotive department, and finally becoming acting locomotive superintendent. In 1888 he was appointed part time lecturer in engineering at Canterbury College, University of New Zealand; two years later he became lecturer in charge of engineering and then professor in charge. At the time of his retirement in February 1923, Professor Scott as the inventor and operator of many of its railway and transportational improvements was probably one of the most prominent figures in New Zealand's world of engineering. The School of Engineering is a lasting memorial to his foresight, initiative, and powers of organization, and, to quote, "it is fitting that the culmination of his work should be its recognition by the government as the national school of engineering of the Dominion." He joined the Institute as an Associate in 1902, advancing to the grade of Fellow in 1913. For an extended number of years he held chairs of engineering and electricity in the University of New Zealand. He was a member of the British Institution of Civil Engineers, serving on its advisory committee, and was also a member of the Institution of Mechanical Engineers.

Edward Dwight Priest, (Assoc. '12) for many years designing engineer in the railway department of the General Electric Company, died at his home in Schenectady March 26, 1931; he was 70 years of age. A native of Northfield, Massachusetts, and a graduate of Worcester Polytechnic Institute (1884), he was employed in 1887 by the Thomson Houston and General Electric Companies where his time was devoted chiefly to railway motor design, in charge of the work. One of his first achievements was the conception of a special-type railway motor light in weight for use on elevated lines. Railway electrification problems were his chief interest and here his contributions to development and improvement were of the greatest value. In 1888 he was the originator of the first box-frame motor ever marketed by his company; this was cast in one piece. In 1901 the electrification of the Manhattan elevated was one of a group of achievements under the leadership of Mr. Priest; as was also a special design of locomotive for the Boston & Ohio Railroad. When William B. Potter became railway department engineer of the General Electric Co. in 1895 he appointed Mr. Priest designing engineer in charge of railway motors, a position which he held until his retirement in 1926.

Beverly L. Worden, (Mem. '27), president of Cutler-Hammer, Inc., New York and Milwaukee, passed away at his home in West Orange, N. J. after an illness of several months. He was born in Chicago 61 years ago and received his B. S. in Civil Engineering from the University of Wisconsin in 1893. In 1901 he founded the Worden-Allen Company of Milwaukee, and in 1909 the Lackawanna Bridge Company of Buffalo; of both of these companies Mr. Worden was president, of the first until 1921, and of the latter until 1924, when he became general manager of the Newark Bay shipyard, Newark, New Jersey, building steel ships for the Emergency Fleet Corporation. For a period prior to the United States' entry into the war he was general manager also of the Submarine Boat Corporation. Early in 1923 Mr. Worden became identified with Cutler-Hammer, Inc., as its vice-president and director, later being chosen president. He was a representative member of several engineering organizations inclusive of The American Society of Mechanical Engineers, the American Institute of Mining and Metallurgical Engineers, and the Western Society of Engineers. For the past number of years he had also been a member of the National Electrical Manufacturer's Association.

Nathan B. Ambler, superintendent of the hydroelectric plant, U. S. Engineering Department, Wilson Dam, Florence, Ala., and well-known as an electrical production engineer, died suddenly April 11 while driving his car in that city to which he had gone as a member of the staff of Hugh L. Cooper, of the Cooper Engineering Corp., consulting engineer for the construction of the Wilson Dam.

A native of Chatham, New York (1876), Mr. Ambler took a four years' course in the electrical engineering department of Columbia University, and for a while thereafter was employed as electrician of the Metropolitan Street Railway Company. This led to work with the Interurban Street Railway Company, which he served as substation foreman. Prior to his association with the Cooper Engineering Corporation, he was superintendent of a Niagara Falls power plant. His membership in the Institute dates from 1903.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institutue records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Collinot, Marcel A., 88 Sherman Ave., Newark, N. J.

Davis, R. H., Westinghouse E. & M. Co., East Pittsburgh, Pa.

DiLucci, A., Box 1051, Chicago, Ill.

Duane, George B., Otis Elevator Co., Yonkers, N. Y.

Gale, R. E., 706 N. 19th St., Boise, Idaho.

Kigar, D. F., 1403 Minnie St., Port Huron, Mich.

Muncy, V. E., Ohio Mechanics Institute, Cincinnati, Ohio.

Prehn, Victor N., 940 Broad St., Newark, N. J.

Van Wyck, P. V. R., Summit, N. J.

Local Meetings

Nebraska Sections Meet with Student Branches

The Nebraska sections of the A. S. M. E. and A. I. E. E. held their annual student meeting in Omaha on April 9, 1931, in cooperation with the Student Branches of both societies at the Universities of Nebraska and South Dakota.

Morning inspection trips included the 4th and Jones Streets plant of the Nebraska Power Company, or the Cudahy Packing Company plant. Afternoon trip opportunities included the Orpheum Theater air conditioning, or Ford Assembly Plant; WOW Broadcasting Station; Northwestern Bell Telephone Building; New Union Station, or Omaha Steel Works.

Dinner was held at the University Club, and during the student program, Phil Ehrenhard, chairman, University of Nebraska Branch, A. I. E. E., served as toastmaster. There was a brief address by Dean H. S. Evans, vice-president, District No. 6, A. I. E. E., and the following talks were given by students:

Human Nature in Engineering, by R. O. Rensch, senior, M. E., University of Nebraska.

Having a Hobby, by A. Steponaitis, chairman, University of South Dakota Branch, A. I. E. E.

Audible Light, by W. E. Stewart and S. M. Geis, seniors in E. E., University of Nebraska.

Several musical numbers were given by students of the University of Nebraska. There were 105 in attendance.

Boston Section Holds Student Meeting

Continuing a plan inaugurated in March 1930, the Boston Section and the student groups of Harvard University, Massachusetts Institute of Technology, Northeastern University, and Tufts College held a joint meeting at the Massachusetts Institute of Technology on the evening of March 26, 1931, with an attendance of 215. During a buffet supper, the students interested in specific fields of electrical engineering were seated at tables with engineers practising in that same field. Thus each student was given opportunity to receive information and advice regarding his favorite kind of electrical work.

M. B. Lambert, vice-president, Westhouse Electric & Manufacturing Company, gave an address on "The Engineer and His Outlook;" this proved to be very interesting to the students and the Section members. There was considerable discussion by both groups, and the meeting was considered one of the most successful of the year.

Toronto Section Holds Luncheon and Evening Meeting

In honor of President Lee and National Secretary Hutchinson, the Toronto Section held a luncheon at the Royal York Hotel, Toronto, March 27, 1931. Present were: D. A. McKenzie and G. D. Floyd, respectively chairman and secretary of the Section; C. E. Sisson and W. L. Amos, respectively vice-president and secretary of District No. 10; A. B. Cooper, director of the A. I. E. E.; I. M. Maclean, J. A. Magley, V. G. Smith, and W. F. Sutherland, members of the Section's executive committee; and T. R. Rosebrugh, F. A. Gaby, H. W. Price, W. A. Bucke, E. T. J. Brandon, W. F. Wright, A. H. Hull, F. R. Ewart, W. P. Dobson, S. E. M. Henderson, C. E. Schwenger, H. C. Don Carlos, M. B. Hastings, E. M. Wood, and F. F. Ambuhl, past chairmen of the Section.

In the evening, G. L. Lillie of the

Toronto Hydro-Electric System presented a paper "Factors in Design of 115/230-Volt Distribution in a Modern Residential District." President Lee addressed the meeting, and his description of problems he had encountered in development of water power sites in Quebec was especially interesting. National Secretary Hutchinson outlined the progress in Institute affairs, and emphasized the desire for constructive criticism and suggestions for the further development of ELECTRICAL ENGINEERING. The attendance was 91.

San Francisco Section Meets With Students

On March 27, 1931 the San Francisco Section held a meeting specially arranged to bring together the Section members and University of California, University of Santa Clara, Stanford University Student Branches. At a dinner preceding the program each student was seated with an engineer practising in the particular field in which the former was especially interested, thus offering excellent opportunities for helpful exchange of information and experiences.

The address of the evening was by R. R. Newell, professor of medicine and director of the department of radiology, at Stanford University Medical School, on the subject "The Use and Misuse of Electricity in Medicine," and was received with great interest. Dr. Newell exhibited many instruments used in making examinations.

Attendance at the dinner and at the address was 118 and 180, respectively.

Pittsfield and Schenectady Section Competition

Following the plan inaugurated last year to encourage their younger members to participate in programs, the Pittsfield and Schenectady Sections held joint meetings in Pittsfield March 17, 1931, and Schenectady April 3, 1931, for the presentation of papers by section members less than 30 years of age and who had not previously presented Institute papers. The programs were as follows:

PITTSFIELD

OPERATION OF THE MERCURY BOILER TUBE WITH HIGH THERMAL STRESSES, by T. C. Ohart, Schenectady.

PULPS AND PAPER IN THE ELECTRICAL INDUSTRY, by M. B. Newell, Pittsfield.

A METHOD OF DETERMINING POWER TRANSFER LIMITATIONS OF LOW-VOLTAGE A-C. NETWORKS, by R. G. Lorraine, Schenectady.

NETWORK TRANSFORMERS, by P. L. Christensen, Pittsfield.

NONTECHNICAL FACTORS AFFECTING THE ELECTRICAL INDUSTRY, by S. A. Holme, Schenectady.

PRECISE FREQUENCY DETERMINATION, by C. W. Ransom, Pittsfield.

SCHENECTADY

NOISELESS ROTATING MACHINERY, by S. J. Levine, Pittsfield.

THE POLYCYCLIC THYRATRON INVERTER, by R. S. Thurston, Schenectady.

LIGHTNING STUDIES ON SMALL HIGH-VOLTAGE TRANSFORMERS, by M. F. Beavers, Pittsfield.

HIGH-VOLTAGE IMPREGNATED-PAPER POWER CABLES, by D. R. Carpenter, Schenectady.

A NEW DEVELOPMENT IN IRON-CORE REACTORS, by T. A. Wilson, Pittsfield.

PREDETERMINATION OF OVERVOLTAGE IN ELECTRICAL SYSTEMS SUBSEQUENT TO LOSS OF LOAD, by J. W. Butler, Schenectady.

Prizes were awarded after consideration of the contents of the papers as well as the presentation. At the Pittsfield meeting, T. C. Ohart of Schenectady received the first prize, and S. A. Holme of Schenectady and C. W. Ransom of Pittsfield tied for second. The total numbers of points were Schenectady 496.3; Pittsfield 445. 85 attended the meeting, and 60 the dinner preceding it.

At the Schenectady meeting, J. W. Butler of Schenectady received the first prize, and T. A. Wilson of Pittsfield received second prize. The total numbers of points were, Schenectady 512.8; Pittsfield 486.4. 150 attended the meeting, and 90 the dinner preceding it.

Student Convention At Swarthmore College

The seventh annual local student convention sponsored by the Philadelphia Section was held at Swarthmore College on March 16, 1931, with seven schools participating: namely, Drexel, Haverford, Lafayette, Lehigh, Pennsylvania, Princeton, and Swarthmore. The program of the morning session was as follows:

WELCOME—Dean Raymond Walters, Swarthmore College

AN AUTOMATIC TIMER FOR RACES, by E. A. Speakman, Haverford College, 1931

VISUAL TESTING DEVICES, by O. H. Schuck, University of Pennsylvania, 1931

ELECTRICAL DETERMINATION OF TENSILE STRENGTH, by William MacNamee, Princeton University

Discussion of above papers.

THE BARTOL LABORATORY, by Dr. T. H. Johnson, Franklin Institute

Those attending the convention were guests of Swarthmore College at luncheon, afterward separating into three groups, according to preference, to visit the Deepwater generating station of the American Gas & Electric and the United Gas Improvement Companies, the Lamokin substation of the Pennsylvania Railroad Company at Chester, Pa., or the General Electric Company switching equipment factory at Darby, Pa.

The latter part of the afternoon there was an inspection trip through the College buildings, followed by a dinner in the Whittier House.

The evening program included an organ recital, by Professor L. R. Shero of Swarthmore College, and the presentation of two papers:

LIFE OF HENRY, by R. M. Mitchell, Swarthmore College, 1931

LIFE OF FARADAY, by W. H. Radford, Drexel Institute, 1931

Three prizes were awarded for the presentation of student papers during the morning session, E. A. Speakman, receiving the first; O. H. Shuck, the second; and William MacNamee, third. Skits were presented by Drexel and Swarthmore students. The registration was 181.

Future Section Meetings

Cleveland

May 21, 1931—Annual dinner meeting. Speaker—W. S. Lee, president and consulting engineer, Duke Power Company, and president, American Institute of Electrical Engineers.

Detroit-Ann Arbor

May 19, 1931—Subject and speaker to be announced later.

June 20, 1931—Spring frolic.

Lehigh Valley

May 16, 1931—Annual meeting. INDUSTRIAL PLANNING FOR THE FUTURE, by E. C. Stone, assistant to senior vice-president, The Philadelphia Company. Meeting to be held at Altamont Hotel, Hazleton, Pa.

Niagara Frontier

May 15, 1931—Subject and speaker to be announced later.

Seattle

May 19, 1931—The best paper submitted in the annual competition for prizes will be presented at this meeting.

Sharon

May 5, 1931—The Contributions of Telephone Research to the Talking Motion Picture Industry, by J. O. Perrine, Associate Editor, *Bell System Technical Journal.*

Spokane

May 22, 1931—Annual dinner meeting. History of the Electrical Development of the Inland Empire, by John B. Fisken. Election of officers.

Toledo

May 22, 1931—Speakers—T. J. Nolan, Toledo Edison Co. and J. T. Greene, Police and Fire Alarm System.

June 12, 1931—Dinner and election of officers. Speaker—E. C. Stone, assistant to senior vice-president, The Philadelphia Company, and vice-president District No. 2, A. I. E. E.

Past Section Meetings

Akron

The Development of Electrical Engineering Since the Invention of the Incandescent Lamp, by Dr. A. E. Kennelly, Professor Emeritus of Electrical Engineering, Harvard University and Massachusetts Institute of Technology. March 25. Attendance 350.

Inspection trip through the Hoover Suction Sweeper plant at North Canton. After dinner, M. L. Pierce gave a talk on Engineering in Selling. April 9. Attendance 80.

Atlanta

The Lighting of the Future, by A. L. Powell, Director, Edison Lighting Institute. Illustrated. Joint meeting with the A. S. M. E. Section. Dinner preceded the meeting. March 23. Attendance 80.

Baltimore

Artificial Lightning, by D. R. Rowland. After the speaker described the new d-c., high-voltage equipment installed at the Locke Insulator Company, those at the meeting adjourned to the laboratory of that company where a demonstration of the one and one-half million volt a-c. equipment and the two and one-half million volt d-c. equipment was given. March 20. Attendance 105.

Cleveland

Industrial Applications of Vacuum Tubes and Photoelectric Tubes, by E. L. Manning, General Electric Company. Illustrated and demonstrated with actual equipment. March 19. Attendance 210.

Connecticut

The Sun Lamp, by Paul Luckenbach, General Electric Co. Illustrated with slides. Meeting held at the Bridgeport Works of the General Electric Co. March 25. Attendance 40.

Dallas

Speed, Unemployment, and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engineering Corp. March 5. Attendance 98.

Engineer's Responsibility, by Dean F. C. Bolton, Texas A. & M. College. Dean George C. Shaad, University of Kansas, and vice-president, District No. 7, A. I. E. E., gave a talk on Institute activities. March 25. Attendance 74.

Denver

Engineering Considerations in the Design of Open Wire Line for Communication, by G. S. Dring, American Tel. & Tel. Co. Illustrated. Dinner preceded the meeting. March 13. Attendance 52.

Dinner and card party. March 20. Attendance 72.

Detroit-Ann Arbor

The Sound of a Shadow, by John B. Taylor, General Electric Co. Joint meeting with the Institute of Radio Engineers. March 17. Attendance 650.

"The United States Should Own and Operate Muscle Shoals" was the subject of a debate presented by students of the Stump Speakers Society from the University of Michigan and Detroit Institute of Technology. The judges decided in favor of the negative, which was supported by the team from the University of Michigan. Joint meeting with the Illuminating Engineering Society, sponsored by the educational committee of the Associated Technical Societies of Detroit. March 24. Attendance 100.

Erie

So-Called Network in A-C. Distribution, by P. F. Pugh, General Electric Co.;

Latest Methods in Mechanical Balancing, by F. M. Kirkpatrick, General Electric Co.;

Load Control, by O. E. Lang, Pennsylvania Electric Co. Members of the Technical Federation of Erie invited. February 17. Attendance 105.

Historical Developments in Electrical Engineering During the Past Fifty Years and the Influence of Same Upon Modern Life and Civilization, by Dr. A. E. Kennelly, Professor Emeritus of Electrical Engineering, Harvard University and Massachusetts Institute of Technology. March 23. Attendance 120.

Fort Wayne

The D-C. Saturable Reactor, by B. A. Case, General Electric Co.;

The Theory of Probability, by W. J. Morrill and E. J. Schaefer both of the General Electric Co. March 12. Attendance 60.

Houston

Recent Developments in High Speed Relaying, Stability, and Lightning Protection on Transmission Systems, by I. T. Monseth, Westinghouse Elec. & Mfg. Co. February 26. Attendance 59.

Speed, Progress, and Unemployment, by Dr. William McClellan, vice-president, Stone & Webster Engineering Corp. March 3. Attendance 26.

The Professional Engineer, by Dean George C. Shaad, University of Kansas, and vice-president, District No. 7, A. I. E. E. March 23. Attendance 23.

Indianapolis-Lafayette

The Cathode Ray Oscillograph and Its Application to the Recording of Natural Lightning, by Professor R. H. George, Purdue University. Illustrated with slides. Joint meeting with the A. S. M. E. Section. April 3. Attendance 70.

Kansas City

Preservation Treatment of Pine Poles, by R. T. Blair, International Creosoting Co. Moving pictures followed. February 24. Attendance 50.

The Missouri River as a Factor in World Trade, by Frank V. Smith, General Electric Co. Film—"The All-Electric Ship California." Joint meeting of all the Engineering Societies in Kansas City. March 6. Attendance 350.

Lehigh Valley

Adventures in Science, by Oliver Ajer, General Electric Co. Demonstrated. Dinner preceded the meeting at the Hotel Sterling, Wilkes-Barre. March 27. Attendance 300.

Los Angeles

Annual joint meeting with the Student Branches of the University of Southern California and the California Institute of Technology, at which the following papers were presented by Students:

The Application of Engineering to the Development of Automobile

Lighting, by Walter Weiss, University of Southern California;

Wave-Form of Current in Converters, by Adin Mathews and Louis Hendrixson, University of Southern California;

Thyratron Theory, by G. W. Read, California Institute of Technology;

Discharge in High Vacuum, by E. O. Erickson, California Institute of Technology;

The Vacuum Switch, by Charles Lash, California Institute of Technology. At the conclusion of the technical session, the Aeronautics Laboratory, Astro-physics Machine Shop, and Electrical laboratories were inspected. March 10. Attendance 300.

Louisville

The Development of Louisville, by E. A. Erskine, Southern Bell Telephone & Telegraph Co. March 20. Attendance 30.

Madison

Some Factors Affecting Noise in Telephone Circuits Arising in Inductive Exposures, by W. C. Lallier, Wisconsin Telephone Co. March 11. Attendance 135.

Memphis

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and vice-president, District No. 4, A. I. E. E. March 25. Attendance 61.

Milwaukee

Building Prosperity Avenue, by H. H. Magdsick, General Electric Co. Illustrated. Joint meeting with the Engineers Society of Milwaukee. March 18. Attendance 275.

The New Physics, by Professor Warren Weaver, University of Wisconsin. April 1. Attendance 93.

Minnesota

Oriental Travelogue, by C. P. Sigerfoos, Professor of Zoology. March 30. Attendance 45.

Niagara Frontier

The Progress of Electrical Engineering During the Last Fifty Years, by Dr. A. E. Kennelly, Professor Emeritus of Electrical Engineering, Harvard University and Massachusetts Institute of Technology. Illustrated with slides. March 20. Attendance 125.

North Carolina

Annual spring meeting. Professor W. S. Rodman, vice-president, District No. 4, A. I. E. E. discussed Institute activities. The following papers were presented, all of which were illustrated with slides:

Telephone Facilities Used by Power Companies, by O. J. Huie, Southern Bell Telephone & Telegraph Co., and Blair Jenkins, Jr., Carolina Power & Light Co.;

Oil Circuit Breaker Developments, by R. M. Spurck, General Electric Company;

Insulation Value of Wood Pole Lines for Lightning Protection, by J. A. Jones, Carolina Power & Light Co. After dinner, Dr. C. L. Fortescue, Westinghouse Electric & Mfg. Co., gave a talk entitled Influence of Recent Lightning Investigations and Studies on Practical Design and Operation of High Voltage Transmission Systems. March 10. Attendance 120.

Oklahoma City

Speed, Unemployment, and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engg. Corp. March 6. Attendance 102.

Rochester

Applications of the Light Sensitive Tube to Industry, by E. H. Vedder, Westinghouse Elec. & Mfg. Co. March 5. Attendance 201.

St. Louis

Development of the Modern Watthour Meters, by Fred Holtz, Sangamo Electric Co. Illustrated with slides. March 18. Attendance 70.

San Antonio

The Professional Society, by Dean George C. Shaad, University of Kansas, and vice-president, District No. 7, A. I. E. E. Following this lecture several motion pictures were shown. March 24. Attendance 78.

San Francisco

Industrial Application of Electricity, by Louis F. Leurey, consulting electrical engineer. The meeting was preceded by dinner at the Engineer's Club. February 27. Attendance 70.

Saskatchewan

Recent Developments of Directional Flying, by W. L. Laurie, Department of Civil Aviation at Ottawa. Illustrated. February 6. Attendance 29.

Schenectady

Historical Developments in Electrical Engineering in the Past Fifty Years, by Dr. A. E. Kennelly, Professor Emeritus of Electrical Engineering, Harvard University and Massachusetts Institute of Technology. March 27. Attendance 250.

Seattle

J. E. Hawe, Great Northern Railway, presented a paper on the result of two years' operation of the Great Northern Railway Electrification. Film—"Wildwood Coal Mines, 100 Per Cent Electrified." February 17. Attendance 81.

Spokane

Recent Developments in Electrical Engineering, by L. W. W. Morrow, editor, *Electrical World.* Dinner in honor of the speaker preceded the meeting. March 10. Attendance 27.

Syracuse

Recent Research Developments, by J. M. Stedman, Westinghouse Electric & Mfg. Co. February 23. Attendance 167.

Audible Light, by John B. Taylor, General Electric Co. March 9. Attendance 580.

Toledo

Vacuum Tubes and Photoelectric Cells in Industry, by E. L. Manning, General Electric Co. March 20. Attendance 800.

Toronto

Standardization, by B. Stuart McKenzie, Canadian Electrical Standards Association. March 13. Attendance 50.

Dependence of Future Research in the Applied Sciences Upon the Development and Refinement of Marketing, by W. W. Goforth, Cockfield Brown & Company. Illustrated. April 10. Attendance 41.

Urbana

Inductive Interference in Telephone Circuits, by W. W. Russell, Illinois Bell Telephone Co. March 11. Attendance 175.

Utah

The following five minute talks were presented by members of the Section:

The Mercury Turbine, by C. B. Shipp, General Electric Co.;

Contactor Control, by V. J. Del Duke, Utah Copper Co.;

Electrical Laboratory Equipment, by J. H. Hamilton, University of Utah;

Insulating Varnishes, by J. A. McDonald, General Electric Co.;

The Overhung Turbine, by B. E. Jordon, Utah Power & Light Co.;

The Synchronous Motor, by R. W. McNeil, Westinghouse Elec. & Mfg. Co. Film—"The Electric Ship." March 16. Attendance 42.

Worcester

Secondary Networks of Present Day, by D. F. Blake, General Electric Co. March 18. Attendance 45.

Past Branch Meetings

Alabama Polytechnic Institute

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and vice-president, District No. 4, A. I. E. E. Professor Rodman also gave a brief history of the Institute. March 19. Attendance 68.

University of Alabama

Turbines, by Professor John M. Gallalee. Film—"Steam Turbines." March 9. Attendance 30.

University of Arkansas

Three films shown: "Dynamic America," "Steam Turbine with a Solid Rotor," and "Body and Soul." March 13. Attendance 53.

Armour Institute of Technology

Michael Faraday, by T. A. McGill, student;

Joseph Henry, by M. J. Schinke, student. March 20. Attendance 40.

University of British Columbia

Carrier Current in Telephony, by H. Van Allen, student. March 17. Attendance 14.

Polytechnic Institute of Brooklyn

A New Method of Scanning for Television, by Ivan Bloch, student;

Mercury Arc Rectification, by William Powers, student;

Breaking the A-C. Arc in Circuit Breakers, by Leonard Evans, student. Ivan Bloch received first prize and William Powers second prize. March 9. Attendance 26.

Bucknell University

Life and Works of Joseph Henry, American Physicist, by Percy Hort, Branch secretary. Film—"Steam Turbine with a Solid Rotor." March 9. Attendance 9.

Talks on the life and work of Archimedes, Galileo, and Sir Isaac Newton, by William Griffith, student. March 30. Attendance 8.

California Institute of Technology

Joint meeting with the Los Angeles Section and the University of Southern California Branch at which six papers were presented by students. (See report under Past Section Meetings).

University of California

Two films shown as follows: "Atomic Hydrogen Welding," and "Straight-Line Production of Induction Motors." Joint meeting with the A. S. M. E. March 11. Attendance 75.

Inspection trip to the Newark substation of the Pacific Gas & Electric Co. March 21. Attendance 31.

Modern Practise in Steam-Plant Design, by R. C. Powell, Pacific Gas & Electric Co. March 25. Attendance 50.

University of Cincinnati

High-Tension Cable and Dielectrics, by Mr. Calvert, General Electric Co. March 4. Attendance 41.

Clarkson College of Technology

Discussion of Branch activities. March 3. Attendance 21.

Colorado State Agricultural College

The Life and Experiments of Michael Faraday, by Oscar Baer, student. March 9. Attendance 9.

Film—"Dynamic America." March 16. Attendance 12.

Annual Engineers' Day held jointly with the A. S. M. E. Branch. The Influence of Gold and Silver Production on Economic Conditions, by Frank E. Shepard, Supt. U. S. Mint in Denver. March 28. Attendance 150.

Cooper Union

Magnetic Shielding of Straight D-C. Conductors, by George C. Neuschaefer and August B. Mundel, students. March 18. Attendance 12.

Cornell University

Two films shown as follows: "The Steam Turbine," and "Dynamic America." March 25. Attendance 23.

University of Detroit

Five moving pictures shown. Talks by Dean R. E. Lawrence, A. W. Mitchell, Chrysler Motor Co., and Professor F. Lysenmeyer. March 19. Attendance 210.

Harvard University

Inspection trip to the General Electric Co. at Lynn, Mass. Match 16. Attendance 25.

Iowa State College

Smoker. April 18. Attendance 140.

State University of Iowa

Film—"Conowingo." February 11. Attendance 40.

Worlds Water Power and the Hoover Dam, by W. B. Knight, student. February 18. Attendance 29.

Development of Television in the United States, by Mr. Kosek, student;

Production of Power from the Tropic Seas, by F. O. Lyddon, student. February 25. Attendance 37.

Rectifiers, by Mr. Ten Eyck, student. Film—"Dynamic America." March 4. Attendance 39.

The Mercury Vapor Turbine, by Mr. Lewis, student;

Later Applications of the Electricity in Transportation, by R. Marchant, student;

Electrical Developments in the Far East, by T. S. Mariano, student. March 11. Attendance 26.

The Cathode Ray Oscillograph, by Mr. Wilkins, student. Film—"Steam Turbine with a Solid Rotor." March 25. Attendance 39.

Kansas State College

Patents and Inventions, by Professor R. G. Kloeffler, counselor. (Afternoon session). February 18. Attendance 70.

The program of the evening session was the same as that of the afternoon session. February 18. Attendance 30.

Talk by E. D. Bell, United Power & Light Corp. (Afternoon session). March 5. Attendance 75.

The program of the evening session was the same as that of the afternoon session. March 5. Attendance 35.

Lehigh University

Psychology of Illumination, by J. B. Sponsler, student;

The Engineer in College and Out, by A. J. Standing, Bethlehem Steel Co. February 18. Attendance 43.

Audible Light, by John B. Taylor, General Electric Co. February 23. Attendance 250.

Talking Movies, by D. C. McGalliard, Electrical Research Products, Inc. March 4. Attendance 250.

Three films were shown: "Steam Turbine with a Solid Rotor," "Mechanized Mine of the Butler Coal Company," and "Dynamic America." March 20. Attendance 154.

Marquette University

Executive Board meeting. March 3. Attendance 8.

Inductance, by Mr. Forman, Louis Allis Manufacturing Co. Election of officers as follows: Ellsworth Ziehm, chairman; Anthony Cain, vice-chairman; Donald Boehmer, Secretary; Robert Manion, treasurer. March 5. Attendance 27.

Massachusetts Institute of Technology

Super-Power Production, by Francis D. Weeks, student;

Power Factor Correction and the Fynn-Weichsel Motor, by Gordon S. Brown and John C. Gibson, students. March 17. Attendance 57.

Inspection trip to the Woburn Station of the Edison Electric Illuminating Co. of Boston, and the Tewksbury substation of the New England Power Association. April 1. Attendance 17.

Michigan College of Mining and Technology

Electric Lighting, by Paul Junttila, student;

Gerald Warrener, Ontanogan Power Project, outlined in detail the routine to be followed in putting up a transmission line. March 11. Attendance 26.

Michigan State College

The Change-Over from 30 to 60 Cycles in Grand Rapids, Michigan, by H. L. Abrahamse, student;

Summer Experiences with the General Electric Company, by R. B. McCall and L. Switzgable, students. March 10. Attendance 23.

University of Michigan

Three students outlined their experiences during summer employment. March 4. Attendance 30.

Mississippi A. & M. College

Finances of American Utilities and Some Peculiar Uses of Electricity, by W. P. Gearhiser, student;

Supernatural Power, Inc., by P. W. Godard, student. March 13. Attendance 24.

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and vice-president, District No. 4, A. I. E. E. March 24. Attendance 31.

Missouri School of Mines and Metallurgy

J. D. Roy, student, outlined student courses given by the Westinghouse Elec. & Mfg. Co. March 11. Attendance 18.

St. Pat's Electrical Show. March 21. Attendance 437.

Engineering Achievements of 1930, by J. E. Stokes and J. D. Shelton, students. Professor I. H. Lovett, counselor, gave a talk on the construction of Bagnell Dam. April 1. Attendance 20.

Montana State College

Cut-Out Designs for Street-Lighting Circuits, taken from *General Electric Review*, presented by Wesley C. Funk, student;

Electric Power in the Lumber Industry, by Jean Smith, student;

Treating Poles, taken from *Western Electric News*, presented by Carl Wall, student. Film—"Arc Welding." March 19. Attendance 151.

University of Nebraska

R. A. Richardson, Program Service Company, outlined problems encountered with the telephone radio and gave solutions to many of these problems. March 11. Attendance 39.

University of Nevada

Modern Radio Stations and Transmitting Equipment, by Mr. Knapp, student. February 25. Attendance 11.

Geophysical Prospecting, by Professor Clark Amens. March 4. Attendance 19.

Electric Power in Connection with the Lumber Industry, by Chester Elliott, student;

New Developments in Photoelectric Cells, by E. H. Tucker, student. March 11. Attendance 12.

Film—"The Single Ridge." March 18. Attendance 23.

Newark College of Engineering

Joint meeting with Rutgers University Branch. Inspection trip through Newark College of Engineering Laboratories. Address of welcome by President A. R. Cullimore, Newark College of Engineering. Short address by Dean P. H. Daggett, Rutgers University. Mr. Whitmore, Fox Film Corp., presented a talk on Making Movietone Pictures. March 9. Attendance 66.

University of New Hampshire

Advantages and Disadvantages of A. I. E. E., by F. Perkins, student;

Suggestions for Improvement of A. I. E. E., by J. Carlen, student;

Membership in A. I. E. E., by R. Williams, student. March 7. Attendance 33.

Election of officers as follows: P. A. Rolfe, chairman; R. H. Williams, Secretary. Film—"Blasting the Water Highways of America." April 1. Attendance 31.

University of New Mexico

The Life of Michael Faraday, by C. E. Henderson, Branch chairman. Election of officers as follows: M. Austin True, chairman; E. W. Huffman, vice-chairman; Stanley O. Fish, secretary-treasurer. April 2. Attendance 11.

College of the City of New York

Film—"Steam Turbine with a Solid Rotor." March 12. Attendance 35.

New York University

Power-Factor Correction, by L. F. Anderson, student;

Operation and Application of the Cathode Ray Oscillograph, by A. E. Bell, student;

Acoustics of Auditoriums, by M. Bogstahl, student. February 16. Attendance 18.

Business meeting. March 2. Attendance 18.

Cooperative Courses, by G. J. Helis, student;

The Mercury Arc Rectifier, by O. M. Lerz, student. March 16. Attendance 17.

Color in the Talkies, by C. Papini, student;

New York City West Side Development, by J. B. McNally, student;

History of Petroleum, by S. Podowitz, student;

Foreign Jobs, by G. J. McGillivray, student. March 30. Attendance 18.

North Carolina State College

Life of Joseph Henry, by L. C. Hubbard, student. March 31. Attendance 34.

North Dakota State College

Engineering and Education, by R. V. Wright, president, American Society of Mechanical Engineers. Joint meeting with the A. S. M. E. Branch. March 30. Attendance 55.

Film—"The Single Ridge." April 1. Attendance 60.

University of North Dakota

Informal talk by Professor D. R. Jenkins. April 1. Attendance 11.

Northeastern University

Traffic Control, by O. M. Jacobi, Submarine Signal Corp. Joint meeting with A. S. M. E. Branch. February 24. Attendance 50.

University of Notre Dame

Transatlantic Telephone Communication, by A. M. Rose, American Tel. & Tel. Co. Patrick Murray, student, presented a review of engineering new items. Joint meeting with the Notre Dame Engineers' Club. March 16. Attendance 187.

Ohio Northern University

Galileo's Life, by Mr. Jacobs, student. April 2. Attendance 14.

Ohio University

What Constitutes an Education?, by E. W. Chubb, Dean of the College of Liberal Arts. Report of the Middle Eastern District Meeting given by Harold Swagart, student. April 1. Attendance 19.

Oklahoma A. & M. Colleg

Rural Electrification, by Don Heffner, student. February 26. Attendance 26.

History of the Electrical Industry and George Westinghouse's Developments, by Mr. Hammond, Westinghouse Elec. & Mfg. Co. March 12. Attendance 41.

A film was presented showing the developments in the oil industry in Oklahoma. Joint meeting with the A. S. M. E., A. S. C. E., and Chemical Engineers. March 26. Attendance 150.

Under Water Cables, by Paul Warren, student. April 9. Attendance 15.

University of Oklahoma

The Life of Michael Faraday, by Roy J. Thompson, student. February 19. Attendance 33.

Maintenance of High-Voltage Lines While in Operation, by Mr. Steele, Oklahoma Gas & Electric Co.;

The Hoover Dam, by Charles Ludwick, student. March 26. Attendance 35.

Oregon State College

A Biography of Michael Faraday, by Elliott MacCracken, student;

Joseph Henry, by Alton Everest, student. March 31. Attendance 39.

Long Distance Telephone Circuit Facilities, by A. K. Morehouse, Pacific Tel. & Tel. Co. April 7. Attendance 42.

Pennsylvania Stat College

Film—"Atomic Hydrogen Welding." January 13. Attendance 132.

Inspection trip. April 11. Attendance 72.

University of Pennsylvania

Discussion of Branch activities. March 5. Attendance 20.

Talk by Professor C. D. Fawcett, counselor. Election of officers as follows: C. N. Maxfield, chairman; W. S. Caldwell, vice-chairman; H. D. Sarkis, secretary; W. H. Young, treasurer. March 23. Attendance 24.

Pratt Institute

Fourth Annual Convention held jointly with the A. S. M. E. and the Wohler Chemical Society. In the afternoon, three papers were presented by students, as follows:

History of Chromium, by L. K. Teubner;

Manufacture of Mazda Lamps, by S. P. Terni;

Principles of Operation of the Linotype, by N. W. Mackenzie.

In the evening the following talks were presented:

Brief addresses, by Dr. S. S. Edmands, Director School of Science & Technology, Ernest Hartford, assistant secy., A. S. M. E., and H. H. Henline, assistant national secy., A. I. E. E.

Our Nation's Health, by Ralph O. Clock, Davis & Geck Co.;

Television, by P. B. Smith, New York Telephone Co. March 25. Attendance 300.

Rensselaer Polytechnic Institute

Stability of Interconnected Systems, by W. E. Mayott, student. Illustrated. March 10. Attendance 150.

How Telephone Communication Serves Modern Business, by B. K. Rhodes, New York Telephone Co. Films—"The Telephone Family," and "The Flying Telephone." The following officers were elected: J. J. Lewis, chairman; F. S. Claassen, vice-chairman; H. A. Schlieder, secretary-treasurer. April 7. Attendance 180.

Rhode Island State College

The Nature of an Engineer's Work with a Public Utility, by D. Daly and J. Knapp, Blackstone Valley Light and Power Association. March 12. Attendance 22.

Business meeting. March 26. Attendance 13.

University of South Carolina

The Hoover Dam, by Charles O. Warren, student;

To Europe Via the North Pole, by J. J. Duffie, student. March 16. Attendance 29.

South Dakota School of Mines

Film—"Steam Turbines." March 10. Attendance 95.

Almon Bjerke elected chairman for next term. March 20. Attendance 32.

University of Southern California

Joint meeting with the Los Angeles Section and the California Institute of Technology Branch, at which six papers were presented by students. (See report under Past Section meetings.)

Southern Methodist University

Electronic Theory and Its Application, by Robert M. Kennedy, Southwestern Bell Telephone Co. Talk and demonstration of a 3.5 meter radio receiver and transmitter by D. J. Tucker, student. F. H. Gable, Branch Chairman, described the new radio station at the university. January 21. Attendance 36.

Description of the new 7½-watt amateur radio station W5 QG of S. M. U., operating on 20 meters, by F. H. Gable, Branch chairman. March 18. Attendance 20.

Stevens Institute of Technology

The Accurate Comparison of Frequencies by Means of the Low-Voltage Cathode Ray Tube, by F. L. Fuller, Branch secretary. March 17. Attendance 20.

Syracuse University

The Life of Faraday, by George Cowell, student;

The Life of Henry, by Paul Greiner, student. March 13. Attendance 24.

The Engineer Five Years After Graduation, by Mr. Pratt, The Niagara & Hudson Power Co. April 10. Attendance 26.

University of Tennessee

Electricity, Past, Present and Future, by C. M. Ripley, General Electric Co. March 12. Attendance 133.

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, vice-president, District No. 4, A. I. E. E. March 27. Attendance 25.

University of Texas

The Overhead Distribution System of the Austin Power Plant, by J. H. Dunaway, student. February 26. Attendance 14.

The North Austin Substation, by H. J. Adams, student;

The East Austin Substation, by J. H. Neidert, student. March 12. Attendance 11.

University of Vermont

Hollow-Spun Concrete Poles, by M. Ciardelli, student;

Measurement of Frequency of Radio Transmitters, by J. J. Hay, student. March 10. Attendance 23.

Short business meeting. Life and Work of Michael Faraday, by E. S. Judkins, student;

Life of Henry, by E. E. Whitney, student;

A description of Faraday's generator was given by Professor R. O. Buchanan. March 24. Attendance 21.

Virginia Military Institute

Film—"Assembly of Ford Cars." March 19. Attendance 49.

Three films were shown: "The Busy Body," "Carboloy," and "The Wings of the Army." April 2. Attendance 50.

Virginia Polytechnic Institute

Films—"Steam Turbine with a Solid Rotor," and "Dynamic America." April 9. Attendance 255.

University of Washington

Film—"Nature's Frozen Credits." February 5. Attendance 34.

The Centralia Power Project, by B. T. Travis, City Light and Fixture Co. February 19. Attendance 26.

The Impulse Generator, by Herbert N. Steen, student. February 26. Attendance 10.

Life of Michael Faraday, by James A. White, student. April 2. Attendance 8.

Washington State College

Business meeting. February 10. Attendance 20.

Cushman Power Project, by Mr. Backemole, student. March 5. Attendance 23.

Films—"King of the Rails" and "The Cascade Tunnel." March 12. Attendance 43.

Washington University

Business meeting. April 2. Attendance 14.

West Virginia University

The following talks were presented by students:

Propagation of Radio Waves, by A. W. Friend;

Building a Substation, by F. E. Watson;

Use of Paper in Electrical Apparatus, by W. N. Engle;

Electric Control Permits Two Elevators in One Shaft, by E. D. Harris;

Construction of the Radio Vacuum Tube, by W. P. McCue;

$28,000,000 Rock Island Hydroelectric Development, by G. H. LeFevre. March 3. Attendance 32.

The following talks were presented by students:

Reducing Transformer Failures Due to Lightning, by C. J. McCormick;

Electrification of the C. M. & St. Paul Railway, by C. F. Stewart;

Power Distribution in Belgium, by K. D. Moss;

Use of Instrument Transformers, by P. Shaff;

Effect of Temperature on Properties of Steel, by T. E. Palmer;

Modern Methods of Emptying Grain Cars, by J. N. Simpson. March 10. Attendance 31.

The following talks were presented by students:

Hydrogen-Cooled Turbine Generators, by C. E. Higgins;

Gas Electric Bus, by C. B. Withers;

Grain Cars Unloaded in Six Minutes, by P. N. Vanney;

Two Elevators in One Shaft, by D. C. Kennedy;

Hydrogen Cooling for Large Generators, by W. C. McMillion;

D-C. Transmission, by H. E. Kerwin. March 17. Attendance 33.

The following talks were presented by students:

Method of Cleaning Coal Gas, by H. A. Lewis;

Electrical Advertising, by R. W. Blair;

Electrically-Heated Garden Plot, by M. L. Sprigg;

Westinghouse Commercial Test Course, by E. D. Harris;

Diesel Electric Locomotive, by C. J. O'Leary. March 24. Attendance 32.

University of Wisconsin

Three films shown as follows: "Building New York's Newest Subway," "Driving the Cascade Tunnel," and "Hydroelectric Power Production." March 25. Attendance 95.

Worcester Polytechnic Institute

Inspection trip through the New England Telephone & Telegraph Company. March 9. Attendance 40.

University of Wyoming

Business meeting. March 3. Attendance 12.

Yale University

The Muscle Shoals Project, by J. N. Buckwalter, student;

Effect of Lightning Voltages on Rotating Machinery, by D. B. Fisk, student;

The Electron Tube and Its Application to Industry, by R. C. Schlitt, student. March 12. Attendance 13.

During the week of March 25th to April 2nd, the engineering seniors went on the annual inspection trip. Attendance 90.

Public Speaking, by Professor Hubert Greaves. Illustrated. April 9. Attendance 29.

Employment Notes

Of the Engineering Societies Employment Service

Men Available

GRADUATE of five-year cooperative school in electrical engineering; speaks Spanish and English fluently; one year study of production methods and five years' of street railway experience. Desires position in any state or nation. Location, immaterial. Age 24. C-9002.

COLLEGE GRADUATE class of 29, B. S. degree in electrical engineering, 25, single. General Electric Test, general engineering and business courses. Interested in position in engineering department of manufacturing or utility company. Available at once. Location, eastern states. C-9003.

1928 GRADUATE ELECTRICAL ENGINEER, 26, married. One year G. E. Test; one year transformer engineering design, six months' railway signaling. Desires position with railway, power, or manufacturing company. Available on short notice. Location, immaterial. C-9001.

GRADUATE ELECTRICAL ENGINEER, 35, experienced large prominent electrical manufacturer, test course, sales and engineering departments, quotation, design, research, dedevelopment, factory engineering supervision, technical reports. Investigation materials, power-factor correction problems and distribution systems. Transformers, motors, generators, switchboards, etc. Desires position, design, sales, consulting, engineering, general technician. Location preferred, east, south. C-7321.

1929 GRADUATE ELECTRICAL ENGINEER, age 24; 15 months of General Electric Test course and first year of advanced engineering course. Now taking graduate work at Harvard Engineering school. Desires position with a future. Location preferred, Cleveland, Ohio. Available in June. C-8979.

ELECTRICAL ENGINEER, E. E. degree, 26, single. General Electric Test course, public utility test experience. Two years' experience sound picture industry. Interested in position with manufacturing company or public utility. Available at once. C-4810.

ELECTRICAL ENGINEER, 30, single, technical graduate, G. E. Test, 10 years design and construction of substations, power plants, electrical railways and mines, 5 years foreign. Desires position as engineer or general foreman. Location, anywhere. Available at once. C-217.

GRADUATE ELECTRICAL ENGINEER, 28, four years' manufacturing experience in production and engineering on electrical motors. Desires position with company where greater opportunities are offered. C-2882.

GRADUATE ELECTRICAL ENGINEER, 35, good technical school. Ten years' experience in electrical station construction and design drafting, including considerable mechanical experience. Latest position superintendent of design and construction of transformer substation. Prefers station design and construction with utility, would consider engineering industrial plant maintenance or operation. C-7043.

GRADUATE ELECTRICAL ENGINEER, 25. Three years electrical test engineer, public utility company. One and one-half years electrical design engineer resistor control devices. Desires electrical engineering position with definite future opportunities. Prefers development and design of signal apparatus. Available immediately. Location preferred, Metropolitan New York, but will consider others. C-8999.

ELECTRICAL ENGINEER, age 28; single, considerable industrial experience; one year as graduate assistant; M. S., Iowa State College, 1930; B. S., Pennsylvania State College, 1925. Desires position as instructor, with the prospect of a permanent teaching position. C-3202.

ELECTRICAL ENGINEER, university graduate, 36, married. Background of eight years' experience electrical testing in field and laboratory. Additional 3½ years' experience in testing and manufacture of radio tubes. Desires position as test engineer with radio tube manufacturer. Location preferred, Metropolitan New York. Available now. B-8817.

ENGINEER, E. E. 1926 Ga. Tech. Age 29, married. Several months drafting with Georgia Power Company. Five years' experience in large sugar mill in Cuba. Four years as chief electrician. Working knowledge of Spanish. C-9027.

1931 ELECTRICAL GRADUATE, single, 23, available immediately. Will receive diploma from Texas University in June. Desires any engineering work with opportunity to advance. Has had experience in bookkeeping and typing. C-9019.

ELECTRICAL AND ILLUMINATING ENGINEER, B. S. and E. E. degree, 31, married. Two years' experience with incandescent lamps. Two years designing motor controllers and pilot switches for large machine tools. Seven years' experience with designing motor starters, speed regulators, resistance specialities, theater dimmers, flood-lighting and window lighting control. Location preferred, New York or California. B-4850.

ELECTRICAL ENGINEER, recent graduate, desires a position in the East with an electrical contractor or with a manufacturing concern for production. C-8975.

GRADUATE ELECTRICAL ENGINEER, single, two years' experience on factory apprenticeship course, electrical and mechanical testing, five years sales engineer in wire and cable industry, four years industrial selling. Desires position as sales engineer or commercial and power sales work with a utility. Location preferred, Eastern United States. B-6002.

COLLEGE GRADUATE, 23, single, B. S. in E. E. in 1929. Eighteen months' experience with service department public utility. Desires position in any electrical line with future and opportunity for advancement. References. Available at once. C-9034.

GRADUATE ELECTRICAL ENGINEER, Columbia University, 1906. Age 45. Twenty-five years' experience with design and general engineering problems of steam-electric generating stations and distribution substations. Desires position as electrical engineer with public utility company or engineering firm. A-5466.

DEVELOPMENT AND RESEARCH ENGINEER, M. E., E. E. with considerable experience and successful record with intricate electromechanical problems involving theory and mathematics, high designing and supervising skill. Radio-frequency circuits and measuring instruments. Remote control and public-address systems. Position desired in New York City. A-165.

SENIOR ELECTRICAL ENGINEERING STUDENT, 23, wishes appropriate opening in electrical industry; manufacturing, test or operating. Best references. Location, immaterial. Available June 22nd. C-9084.

ELECTRICAL ENGINEER, 1930, age 31, single, U. S. citizen. Graduate from an engineering college of a "big-ten" university. Telephone and machine shop experience. Speaks Greek besides English. Wishes permanent position in any engineering field. Location, immaterial, go abroad. C-9075.

UTILITIES ASSISTANT EXECUTIVE or local manager. Trained mechanical, electrical, and refrigerating engineering. Experienced operating, construction, engineering, management, public relations, selling, general business administration, accounting. Most valuable to organization desiring to effect maximum economy operating moderate sized property or division larger property. Now engaged, own business. Willing to prove value to employer, salary moderate to start. C-9050.

ELECTRICAL ENGINEER, married, with 20 years' electric utility operating experience in engineering, construction, maintenance of distribution and transmission lines. Substations, first-aid and educational work. Experience in solving radio interference problems. Can qualify as electrical superintendent or assistant to manager. Proved record of qualifications. C-7700.

GRADUATE ELECTRICAL ENGINEER, B. S. degre 1928, single, age 25. Two years' electrical distribution experience; one year of research work. Desires position with a public utility or manufacturing concern. Willing to start at bottom of any work with a future. Available on short notice. Location preferred, Eastern United States. C-7341.

TECHNICAL GRADUATE desires position with public utility. Twelve years' experience on overhead transmission and distribution, design, estimates, field checks, etc. Age 37, married. B-9248.

ELECTRICAL AND RADIO ENGINEER, four years' experience in research and development. Designing, constructing, servicing, and experimenting with radio circuits, amplifiers, vacuum tubes, and sound recording. Three years with research bureau of power company. Testing, checking, and calibrating laboratory instruments, relays, station apparatus. Prefers New York or vicinity. C-3087.

ELECTRICAL ENGINEER, 1928 graduate of a recognized university, 26, single. One year public utility experience, 1½ years as special apprentice on large electrified railroad. Available on short notice. C-9112.

ELECTRICAL ENGINEER, 34 years old, with extensive machine-shop experience in production and maintenance; also power house, and machine designing. Graduate of Cooper Union Institute of Technology. Willing to go anywhere. Good reference. C-1360.

SWITCHBOARD ENGINEER, age 30, single, American citizen, German college education. Six years practical electrician. Five years with Westinghouse Electric and Railway Supply Co. Thoroughly familiar with design, layout and construction of slate and steel panels. Expert in wiring diagrams; power and control circuits, relay applications and metering schemes. C-9037.

PROFESSOR OF ELECTRICAL ENGINEERING, 32, married, B. S. (E. E.) and E. E., three years with General Electric Company, five years with public utility, four years' teaching and administrative experience in state university. Excellent references. Available for next academic year. Correspondence invited. C-7152.

ELECTRICAL ENGINEER, 1930, B. S. in E. E., 24 years old, desires connection, any kind of work except sales or radio. Location, immaterial. C-9105.

GRADUATE ELECTRICAL ENGINEER, age 28, married, 8 years of industrial control, power plant design, and construction supervision experience with contractor. Desires position with public utility or manufacturing concern's engineering or construction departments. Location desired, Middle West. C-4428.

ENGINEER, age 42, electrical wiring layouts for industrial plants and buildings of a large variety for engineers, contractors and architects; also experienced in construction and operation. Location desired, New York City or Northern New Jersey. B-5068.

GRADUATE ELECTRICAL ENGINEER, 25, B. S. degree '29. Nineteen months' experience on general electric test, including 8 months as assistant foreman and foreman of power mercury arc rectifier test. Desires connection with operating or construction company in East or Middle West. C-9089.

ELECTRICAL ENGINEER, graduate, 33, married, 13 years' office and field experience design and construction power plants, substations, distribution systems, industrial electrifications, etc. Familiar with motors and control; some steam experience. Six years in Latin-America in positions of responsibility; fluent Spanish. Used to handling men. Seeks permanent connection in U. S. A. C-8553.

ELECTRICAL DESIGN DRAFTSMAN OR CHECKER, age 31, single, fourteen years' experience on power plant, high- and low-voltage substation and automatic railway substation design. Equivalent of college education. Available immediately. Location, immaterial. B-8628.

PROFESSOR OF ELECTRICAL ENGINEERING, Ph. D., wishes position as head of department of electrical engineering in a growing institution. Excellent general electrical engineering teaching and practical experience. B-660.

GRADUATE ELECTRICAL ENGINEER, 31, single, 8 years' experience, design and construction of transmission lines, voltages up to and including 220 kv., outdoor and indoor high-voltage substation and distribution networks. Desires position in engineering or construction department of large utility or holding company. Location, immaterial. C-3564.

ELECTRICAL ENGINEER, 28. Nine years' varied experience with power and communications companies. Successful design and supervision of experimental apparatus construction. Special transmission work with network and cables. A-c. measurements, high-voltage test, telephone plant work. Graduate Georgia Technology cooperative course. Location, preferred, New York or vicinity. C-9044.

GRADUATE ELECTRICAL ENGINEER, of Purdue University with 18 years' experience in design, construction, estimating, costs, valuation and appraisal of power plants, substations, transmission lines and industrial plants including five years in heavy electric traction and rapid transit work. Open for opportunity with future. C-8256.

SALES ENGINEER, electric specialties; experience in utilities engineering, also illumination and fixture manufacture. Available with two weeks' notice. Salary or commission. C-2942.

ELECTRICAL ENGINEERING GRADUATE, experienced in sales, contact, lecturing and promotion work. Desires position as representative along utility or heavy-duty industrial equipment lines. Location, Eastern preferred. B-4067.

1929 GRADUATE, E. E., age 23, married One year experimental work on steam turbines, half year laboratory assistant to research engineer of electric manufacturing company. At present unemployed. Location, immaterial. C-9132.

EXECUTIVE OR STAFF ASSISTANT, engineering education. Fourteen years' broad experience with manufacturing, utility, and industrial surveys covering: cost reduction, production planning, standards, wage incentives, scientific management methods, statistical control systems, expense and cost analysis. Capable organizer. Profitable assistant to busy executive. Prefers East. Consider any proposition. B-9122.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St. San Francisco N. D. Cook, Manager	205 West Wacker Drive Chicago A. K. Krauser, Manager	31 West 39th St. New York W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

RECENT GRADUATE ELECTRICAL ENGINEER, single, age 25. Desires engineering work. Has had experience in drafting. Location, United States or foreign. Available immediately. C-8437.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, 24, married, excellent physical condition. One year's experience in electric-shovel construction. Desires position with future. Location and salary immaterial. Best of references. Available at once. C-9142.

MECHANICAL - ELECTRICAL ENGINEER, American, 37 years old, six years in charge of factory manufacturing 700 tons of raw sugar daily, factory employing 250 men. Has done considerable original work in welding. Capable of supervision of the design, layout, construction of plants handling large tonnage. C-9052.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, age 25 and single. Experienced in machine-shop and steel-construction work. Four years of practical and theory of electricity in college. Willing to start at the bottom and work up with a reliable company. Available at any time. Location anywhere in United States. C-9135.

GRADUATE ELECTRICAL ENGINEER, 24, two years' manufacturing experience. Desires position on university staff with opportunity to work on Master's degree. Available September. C-9157.

1931 GRADUATE ENGINEER, single, age 24. B. S. in E. E. from University of Kansas in June. Prefers junior engineer work in public utility or manufacturing concern. Willing to begin at bottom where ability, productivity, and personality will produce advancement. Good student. Best of references. Available June 1931. Anything anywhere considered. C-9094.

ELECTRICAL ENGINEER, American, 40, married. Experienced in power generation, transmission, distribution and application to industrial uses. Work covers layout, constuction, operation, maintenance, and repairs. Desires position as electrical engineer with manufacturing concern generating its own power or with utility company. Speaks Spanish. Available on reasonable notice. C-502.

SWITCHBOARD FOREMAN, 10 years' experience with construction companies for public utilities, wiring, construction and installation of power house switchboards and control apparatus. Shop experience, manufacturing switchboards. C-4831.

MANAGER OR SUPERINTENDENT, 47, married. Executive, electrical or industrial. Successful organizer, fficient operator. Knows men; can handle them. Expecially interested in properties not now paying, where future depends on results. Reads, writes, speaks Spanish. Capable earning six thousand up. Available reasonably short notice. Location, not particular; prefers Western United States. C-8777-312-C-1-San Francisco.

ELECTRICAL ENGINEER, B. S. in E. E. 1930, age 25, single. Some steel mill operating experience. Now employed on G. E. test. Desires permanent position with utility company in construction, maintenance, or design work. Good references and personality. C-9159.

GRADUATE ELECTRICAL ENGINEER, 1930, single, six months on Westinghouse engineering course covering tests n switchboards, circuit breakers, regulators, motors, generators, etc. Nine months supervising telephone conduit and cable plant construction and telephone cable testing. Excellent physical condition. Desires permanent position with good future. Location, immaterial. C-9158.

ELECTRICAL ENGINEER, college graduate, 31, married. Eleven years in station, transmission, and distribution designs; system operation and planning; superintendence of meter and relay department; studies, reports and calculations. Good theoretical as well as practical background. Accustomed to responsibilities. Prefers New York or environs but will consider good proposition elsewhere. B-9401.

1930 GRADUATE ELECTRICAL ENGINEER, 23, single. Has had four months on Westinghouse Student Course and considerable industrial experience preceding graduation. Desires to connect with a public utility company. Location, immaterial. Available on two weeks' notice. Good references. C-9150.

ELECTRICAL ENGINEER, B. S. in E. E., 1927, single. Twenty months' experience in design and testing of fractional hp. motors; two years' industrial plant experience. Familiar with motors and control equipment. Desires position as lectrical engineer. Location, immaterial. C-9168.

ASSISTANT PROFESSOR OR INSTRUCTOR IN ELECTRICAL ENGINEERING, 33, married, six years' administrative and teaching experience both E. E. and M. E. subjects. Position desired with technical school in South or West where opportunity is offered for advanced study and research. Available September. C-9166.

Membership

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before May 31, 1931.

Anderson, F. E., Dept. of Public Works, State of Calif., Sacramento, Calif.
Angle, W. P., Virginia Electric & Power Co., Richmond, Va.
Archer, E. T., (Member), E. T. Archer & Co., Kansas City, Mo.
Atkinson, E. S. (Member), H. B. Sherman Mfg. Co., Battle Creek, Mich.
Beavers, M. F., General Electric Co., Pittsfield, Mass.
Becker, F. G., Electrical Trades School, Cincinnati, Ohio
Benson, C. R., General Electric Co., San Francisco, Calif.
Betz, L. G., Public Service Electric & Gas Co., Hackensack, N. J.
Blum, R. A., Buffalo General Electric Co., Buffalo, N. Y.
Brackett, C. H., Union Carbide Co., Niagara Falls, N. Y.
Brennan, J. J., Memphis Power & Light Co., Memphis, Tenn.
Browne, T. E., Jr., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Bunker, F. C., (Member), General Electric Co., Houston, Tex.
Byron, T. J., New York Telephone Co., Albany, N. Y.
Cain, W. W., Consolidated Gas Co., New York, N. Y.
Cutting, F. S., (Member), 98 Carolina Ave., Providence, R. I.
Donabar, H. F., 2325 No. 50th St., Milwaukee, Wis.
Drew, C. E., (Member), R. C. A. Institute, Inc., New York, N. Y.
Duncan, R. L., (Member), R. C. A. Institute, Inc., New York, N. Y.
Durnin, E. J., Saskatchewan Power Commission, Saskatoon, Sask., Can.
Eason, R. K., General Electric Co., Beaumont, Tex.
Edwards, D. V., Electrons Inc. of Delaware, Newark, N. J.
Edwards, G. W., Cleveland Railway Co., Cleveland, Ohio
Ellis, E. A., Atlantic Electric Co., Boston, Mass.
Essington, H. M., (Member), Chicago Surface Lines, Chicago, Ill.
Findlow, C. W., Amalgamated Electric Corp., Toronto, Ont., Can.
Frank, W., 312 Fredericka St., North Tonawanda, N. Y.
Fuller, H. W., Saskatchewan Power Commission, Regina, Sask., Can.
Gallagher, D. H., Public Service Electric & Gas Co., Orange, N. J.
Garstang, W. W., P. R. Mallory & Co., Inc., Indianapolis, Ind.
Gilliatt, C. F., Toronto Hydro Electric System, Toronto, Ont., Can. (Applicant for re-election)
Gledhill, C. L., Public Service Electric & Gas Co., Newark, N. J.
Hillebrand, A. G., Spicer Mfg. Corp., Toledo, Ohio
Hogg, T. H., (Member), Hydro-electric Power Comm. of Ontario, Toronto, Ont., Can.
Horn, R. S., Raydio Ray Corp., Spokane, Wash.
Jansson, M. E., D. Van Nostrand Co., Inc., New York, N. Y.
Jenkins, R. D., Atchison, Topeka & Santa Fe Railroad, Albuquerque, New Mexico
Johanson, C. G., Jr., N. E. P. Engg. & Service Corp., Boston, Mass.
Johnson, G. W., Texas Power & Light Co., Palestine, Tex.

Transfers

Recommended

The Institute's board of examiners at its meeting of March 25, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

McNEELY, JOHN K., professor of elec. engg., Iowa State College, Ames, Iowa.
PETURA, FRANK J., general purchasing engr., Henry L. Doherty & Co., New York.
REID, HARRY, president, Electric Management & Engineering Corp., New York.

To Grade of Member

ALMQUIST, MILTON L., telephone engr., American Tel. & Tel. Co., New York.
BAILEY, JULIAN C., general engr., Columbia Engg. & Mgt. Corp., Cincinnati, Ohio.
BARNES, MARION S., sales agent, General Electric Co., San Francisco, Calif.
CANFIELD, DONALD T., asst. professor of elec. engg., Purdue University, Lafayette, Indiana.
CASEY, EDWARD A., district engr., Anaconda Wire & Cable Co., New York.
CASSELL, RAYMOND L., asst. to president, W. S. Lee Engineering Corp., New York.
CHAMPREUX, ALFRED J., transmission and protection engr., Pacific Tel. & Tel. Co., Seattle, Wash.
COFFIN, JOHN R., engr., Jackson & Moreland, Boston, Mass.
COPELAND, MARK W., Voorhees, Gmelin & Walker, New York.
DIEFENDERFER, JOHN H., asst. to supt. of distribution, Pennsylvania Power & Light Co., Hazleton, Pa.
FARNHAM, WILLIAM E., local traffic engineer, American Tel. & Tel. Co., New York.
FAWCETT, ORVILLE E., maintenance engr., West Penn Power Co., Pittsburgh, Pa.
FOERSTER, JOHN A., general electrical supt., City Hall, Prince Albert, Sask., Canada.
FRANK, AUGUSTUS A., chief engineer, N. Y. Telephone Co., New York.
GORHAM, ROBERT C., asst. prof. of elec. engg., University of Pittsburgh, Pittsburgh, Pa.
GRISWOLD, DEMETRIUS W., manager and chief engr., The British Plaster Board Ltd., Cheshire, England.
KENT, HARRY E., asst. engr., National Electric Light Association, New York.
LANE, FREDERIC ALLEN, electrical engr., American Gas & Electric Co., New York.
LITTLE, THOMAS J., manager, transmission sales dept., Anaconda Wire & Cable Co., New York.
PARKER, CARLETON H., asst. line signal supervisor, United Electric Railways Co., Providence, R. I.
RODRIGUEZ, RODOLFO CID, chief electrical engr., National Railways of Mexico, Mexico, D. F.
ROYDEN, GEORGE T., division engr., Mackay Radio & Telegraph Co., San Francisco, Calif.
TOWNSEND, ARTHUR, chief inspector, Saskatchewan Power Commission, Regina, Sask., Canada.
TULLAR, CHARLES E., manager, patent dept., General Elec. Co., Schenectady, N. Y.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during March are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

AVIGATION. By Bradley Jones. N. Y., John Wiley & Sons, 1931. 314 pp., illus., diagrs., 8 x 5 in., cloth. $2.75.——A brief textbook, intended to give the aviator a practical knowledge of the subject. The instruments used, methods of computing distance and track, drift correction standard and short methods for finding position by astronomic methods, radio navigation and fog flying are discussed.

TURBINEN-SCHNELLAÜFERN, Theorie und Bau. By Viktor Kaplan and Alfred Lechner. München, R. Oldenbourg, 1931. Illus., diagrs., 10 x 7 in., cloth. 18-r. m. ——This book, which is an entirely rewritten edition of Professor Kaplan's former work, "Bau der rationellen Francis Turbinen-Laufraeder," contains an account of the practical and theoretical results of his many years of experimental work upon high-speed turbines, and of the development of the Kaplan turbine. The principles of runner design and methods of regulation are set forth and illustrated by actual installations. Professor Lechner presents a summary of the hydromechanical investigations that have interest to the turbine designer, and a statement of turbine theory.

SYMPOSIUM ON AIRCRAFT MATERIALS. American Society for Testing Materials. Phila., 1930. 192 pp., illus., diagrs., 9 x 6 in., cloth. Price not indicated.——Contains eighteen papers by various engineers discussing matters of metals, alloys, woods and textiles used in constructing aircraft, aircraft finishes, the use of stampings and castings, failures of engine parts, specifications, mechanical and X-ray testing, welding procedure and heat treatment.

INDUSTRIAL ACCIDENT PREVENTION; a Scientific Approach. By H. W. Heinrich. N. Y., McGraw-Hill Book Co., 1931. 366 pp., illus., tables, 8 x 6 in., cloth. $4.00.——A very thorough presentation of the essential principles of accident prevention, based upon long practical experience. The author describes, step by step. the procedure for determining the causes of accidents, the selection and application of the remedy, safety psychology, etc. Many good methods of guarding machinery are shown.

AMERICAN DIESEL ENGINES. By L. H. Morrison. N. Y., McGraw-Hill Book Company, 1931. 606 pp., illus., diagrs., tables, 9 x 6 in., cloth. $5.00.——This book will interest the prospective purchaser and the operating engineer. It discusses comparative costs of Diesel and steam plants, the operation and adjustment of Diesel engines and their suitability for various kinds of work. It also gives descriptions of engines being made at present in this country, and parts.

STANDARD FOUR-FIGURE MATHEMATICAL TABLES. 2 vols. (1 vol., Edition A; 1 vol., Edition B). By L. M. Milne-Thomson and L. J. Comrie. Lond. & N. Y., Macmillan Co., 1931. 245 pp. each vol., diagrs., 11 x 8 in., cloth. $4.50 each vol.——This work is intended to provide a comprehensive table of the numerical values of the elementary functions that are in constant use in the applications of mathematics in physics, engineering, statistics, etc. It includes a number of tables on trigonometrical functions with the argument in radians, hyperbolic functions, inverse trigonometrical and hyperbolic functions, natural logarithms and powers of *e*. Edition A has positive characteristics in the logarithms; edition B, negative characteristics

RELAYS IN AUTOMATIC TELEPHONY; Their Construction, Design and Adjustment, together with the Theory of Impulsing and the Measurement of Time Lags. By R. W. Palmer. N. Y., Isaac Pitman & Sons, 1930. 192 pp., illus., diagrs., 7 x 5 in., cloth. $3.00.——A textbook in which the subject is explained clearly and simply.

QUALITATIVE CHEMICAL ANALYSIS. By Herman T. Briscoe. N. Y., D. Van Nostrand Co., 1931. 279 pp., diagrs., 9 x 6 in., cloth. $2.25.——A comprehensive treatment of the subject, intended for students with some knowledge of general chemistry. The first half of the book presents the theories and principles of electrolytic solutions and the properties of the various anions and cations which are involved in the analytical procedures. The second half gives a practical laboratory course.

ORGANIZATION ENGINEERING. By Henry Dennison. N. Y., McGraw-Hill Book Co., 1931. 204 pp., 8 x 5 in., cloth. $2.00.——This book discusses the problems of group action and points out some of the conditions necessary for effective organization work. The characteristics of human nature are surveyed, methods for guiding and increasing joint productivity considered, and the principles of organization structure set forth.

ILLUMINATING ENGINEERING EQUIPMENT, THEORY AND DESIGN. By L. B. W. Jolley, J. M. Waldram and G. H. Wilson. N. Y., John Wiley & Sons, 1931. 709 pp., illus., diagrs., tables, 10 x 6 in., cloth. $12.00.——Starting with an account of the fundamental principles of illumination, the authors next describe the varieties of electric lamps used as sources of light, and then take up the question of lighting equipment. This topic is the major one of the book and is treated at length. The types of equipment for various purposes; their mechanical design; reflecting, diffusing and refracting media; projecting systems; color media; and equipment for the stage, advertising, studios, etc. are discussed. A section is also devoted to auxiliary equipment. Of use to everyone interested in the selection of equipment.

COMMUTATRICES ET CONVERTISSEURS ROTATIFS. By M. Barrère. Paris, J. B. Baillière et Fils, 1931. Illus., diagrs., 9 x 6 in., paper. (No price given).——A practical textbook upon the theory and design of rotary converters.

COMMUNICATION NETWORKS, v. 1; Classical Theory of lumped constant networks. By Ernst A. Guillemin. N. Y. John Wiley & Sons, 1931. 425 pp., diagrs., 9 x 6 in., cloth. $5.00.——Existing texts on the principles of communication, the author states, deal with the theory and practical significance of special types of networks commonly used in radio or telephone circuits. In the present book an attempt is made to take a broader view, by considering matters that are not of direct practical use, and thus to give the student a more thorough grasp of the fundamental methods of attack upon network problems in general. A succeeding volume on the theory of lines, cables and filters will appear next fall.

BARLOW'S TABLES OF SQUARES, CUBES, SQUARE ROOTS, CUBE ROOTS AND RECIPROCALS of all Integer Numbers up to 10,000. 3rd edition, edited by L. J. Comrie. London, E. & F. N. Spon, 1930. 208 pp., 9 x 6 in., cloth. 7/6.——For 90 years Barlow's Tables have been printed from the plates prepared for De Morgan's edition of 1840. The present edition is reset from modern type, and advantage taken of the opportunity to restore certain tables omitted from the second edition, some valuable new ones added, and certain other improvements effected.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

ORDER FORM FOR REPRINTS OF FULL PAPERS ABRIDGED IN THIS ISSUE OF *ELECTRICAL ENGINEERING**

	(May 1931) Number	Author	Title
☐	31-12	J. W. Milnor and G. A. Randal	The Newfoundland-Azores High-Speed Duplex Cable
☐	31-36	J. H. Ashbaugh	Automatic Regulators in Industries
☐	31-44	R. N. Southgate, A. S. Brookes, E. R. Whitehead and W. G. Roman	Impulse Tests on Substations
☐	31-68	B. F. Bailey	Measurement of Noise in Electrical Machinery
☐	31-73	E. A. Bishop	Noise Mitigation in Substations
☐	31-76	E. H. Hull and W. C. Stewart	Elastic Supports for Isolating Rotating Machinery
☐	31-78	Quentin Graham, Sterling Beckwith, and Frank H. Milliken	Magnetic Noise in Synchronous Machines
☐	31-80	T.G. Castner, E. Dietze, G.T. Stanton, and R. S. Tucker	Indicating Meter for Measurement and Analysis of Noise
☐	31-81	H. B. Marvin	The Measurement of Machinery Noise
☐	31-84	J. P. Foltz and W. F. Shirk	Induction Regulator Noise

*Members, Enrolled Students and subscribers are entitled to one complete copy of any paper abridged if it is requested within one year from date of its publication in ELECTRICAL ENGINEERING. Thereafter a charge of twenty-five cents per complete copy will obtain.

Selected Items *From* Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translation of foreign articles at cost.

Arcs

ELECTRIC. Dynamisches Verhalten des Lichtbogens nach Untersuchung mit dem Kathodenoszillographen (Dynamic Behavior of Electric Arc According to Study With Cathode Ray Oscillograph), H. Klemperer. *Archiv fuer Elektrotechnik*, vol. 25, no. 1, Jan. 27, 1931, pp. 73-80, 15 figs. Purpose of study is to investigate whether arc, after elapse of 1/100,000,000 sec., already has properties of stationary arc.

Armatures

WINDINGS. Die einfache Ausfuehrung der Bruckloch-Ankerwicklungen fuer Wechselstrom (Simple Method for Design of A-C. Armature Windings), T. Seike. *Elektrotechnik und Maschinenbau*, vol. 49, no. 2, Jan. 11, 1931, pp. 21-29, 13 figs. Simplified method for laying out of a-c. windings in which number of slots per pole and phase contains fractional value; method is developed for three-phase windings but can equally well be applied to single phase windings.

Atmospheric Electricity

MEASUREMENTS. Ueber die Messmethoden der elektrischen Leitfaehigkeit der Atmosphaere (Measuring Methods for Electric Conductivity of Atmosphere), J. Scholz. *Physikalische Zeit.*, vol. 32, no. 3, Feb. 1, 1931, pp. 130-139, 4 figs. Two sensitive apparatus were used to exclude meteorologic influences; it was shown that in comparative measurements, if possible, determination of potential gradient with radioactive sounding equipment should take place at great distance from location of observation, as deviations of over 100 per cent were often noticed.

Cables

FAULT LOCATION. Finding Cable Sheath Faults, J. Erickson. *Elec. World*, vol. 97, no. 9, Feb. 28, 1931, p. 409, 1 fig. Simple method, that makes use of only 6-volt battery, galvanometer and length of wire, has been found to be unusually accurate in locating conductor-to-sheath faults in lead-covered parkway cable on series street lighting systems.

INDUCTANCE. The Inductance Coefficients of a Part of a Circuit, and Their Applications, A. Russell. *Inst. Elec. Engrs.—Jl.*, vol. 69, no. 410, Feb. 1931, pp. 270-280, 9 figs. Theoretical mathematical study applied to electric cables and their sheath losses.

INSULATING MATERIALS. Cable Terminal Box Compounds, E. Woodrow. *Elec. Engr. Australia and New Zealand*, vol. 7, no. 10, Jan. 15, 1931, pp. 355-358, 1 fig. Defects that arise in insulating compounds and properties that are required; characteristics of what is considered ideal compound, and methods used and precautions to be taken in filling terminal box with such compound.

LEAD SHEATHING. Lead Sheaths for Cables, N. A. Allen. *Elec. Rev.*, vol. 108, nos. 2777 and 2778, Feb. 13, 1931, pp. 275-276 and Feb. 20, pp. 321-322, 5 figs. Cables with pure-lead sheaths will, sooner or later fail; examples of cases where this may have been are cited; notes on lead-improving alloys; lead-antimony research.

LOSSES. Contributo Allo studio delle perdite dell'autoinduzione dei cavi unipolari armati con fili di ferro (Losses and Self Induction in Steel Armored Single-Conductor Cables), L. Bosone. *Elettrotecnica*, vol. 18, no. 1, Jan. 5, 1931, pp. 2-8, 6 figs. Distribution of magnetic field in armor and calculation of losses; diagrams and tables checked by experimental research. Bibliography.

OIL-FILLED. Oil Reservoir on Cable Joint Saves Material, O. L. Riggs. *Elec. World*, vol. 97, no. 10, Mar. 7, 1931, p. 465, 1 fig. Material and pole space may be saved in three-conductor type "H" aerial cable by mounting oil reservoir on joint itself; in this way running of long hose from pole to joint may be avoided.

Oil-Filled Cable Lines in London, C. E. G. King. *Elec. Times*, vol. 79, no. 2050, Feb. 19, 1931, pp. 231-234, 12 figs. 66,000 volt oil-filled cable of British grid system which are now in operation linking up Hammersmith, Battersea and Fulham power stations of London Power Company.

TELEPHONE. Telephone Cables—N. A. Allen. *Elecn.*, vol. 106, no. 2753, Mar. 6, 1931, pp. 360-361, 3 figs. Recent improvements in design of short distance types for subscribers' circuits.

TESTING. Earth Currents, R. N. Pegg. *Elec. Rev.*, vol. 108, no. 2779, Feb. 7, 1931, p. 370, 2 figs. Tests indicate that small currents in cable sheaths do not necessarily denote high-resistance faults.

Circuit Breakers

COMPRESSED AIR. Latest Developments in Compressed-Gas Circuit Breaker Design, O. Mayr. *AEG Progress*, vol. 7, no. 1-2, Jan.-Feb. 1931, pp. 30-32, 8 figs. Outdoor type of compressed-gas breaker up to 100-kv. working voltage and its operating characteristics.

OIL. Neuer Motorschutz-Oelschalter mit Fernbetaetigung (Novel Remote Control Protective Motor Oil Circuit Breaker), A. Cohn. *Elektrotechnische Zeit.*, vol. 52, no. 9, Feb. 26, 1931, pp. 259-260, 6 figs. AEG-MSBO equipment for 550 volts, 60 amperes is non-interlocked push-button control remote control breaker, suitable for heavy duty intermittent operation; bi-metal stripping is used; high speed magnetic short circuit is employed which makes interrupting of currents up to 10,000 amperes possible.

TANK PRESSURE. Pressure Phenomena in Oil-Circuit Breakers, W. M. Leeds. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 152-156, 14 figs. Oscillograph records of pressure in medium and high-speed breakers show that tank walls are subjected to pressure surges of very steep wave-front having definite frequency between 10 and 60 cycles per sec.; from results of large number of laboratory tests, theory has been developed to account for these pressure waves.

Condensers

Synchronous Versus Asynchronous Condensers, A. Mandl. *AEG Progress*, vol. 7, no. 1-2, Jan.-Feb. 1931, pp. 47-53, 5 figs. It is investigated in which instances it is advisable to employ synchronous or asynchronous condenser; subject matter is based on condensers of medium and large capacity; range of output between 6000 and 60,000 kva. for regulating voltage of correspondingly large networks.

POWER FACTOR IMPROVEMENT. Starkstrom-Kondensatoren zur Blindstrom-Kompensation und ihre Wirtschaftlichkeit in Industrieanlagen (Electric Condensers for Reactive Power Compensation and their Economy in Industrial Installations), H. Cypra. *Elektrizitaet im Bergbau*, vol. 5, no. 11, Nov. 15, 1930, pp. 216-219, 6 figs. Advantages over rotating phase correcting machinery; no-load consumption of condensers practically is negligible, they do not need supervision and require no extra operating room; AEG equipment is illustrated.

SYNCHRONOUS. Developments in Hydrogen-Cooled Condensers, C. J. Fechheimer. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 165-169 and 178, 5 figs. Devices incorporated to safeguard equipment in practically every conceivable way are briefly described, repetitions of previous publications being avoided wherever possible; it is believed that tendency in future will be toward simplification, and reduction in number of auxiliary devices; test results are given. Bibliography.

Control

BRIDGES. Variable Voltage Control Improve Bridge Operation. *Elec. West*, vol. 66, no. 3, Mar. 1, 1931, pp. 141-143, 3 figs. West Spokane Street Bridge in Seattle; from engineering standpoint is unique not only in layout and design of its apparatus but also because it is first on Pacific coast and one of first in country to utilize advantages of variable voltages for controlling leaf movement; by use of separate motor-generator set, source of variable armature voltage is provided for regulating speed of driving motors.

REGENERATIVE. Le freinage électrique en courant continu des trains sur pentes (Electric Braking with Direct Current of Trains on Slopes), E. Gratzmuller. *Industrie Electrique*, vol. 40, no. 926, Jan. 25, 1931, pp. 33-42, 5 figs. Tentative study of principles in braking with recuperation of energy under normal speed and transitory high speeds.

Regenerative Control in Paris, Bacqueyrisse. *Tramway and Ry. World*, vol. 69, no. 8, Feb. 12, 1931, pp. 83-84. Reply to British viewpoint of regenerative control; application to British Systems; gear ratio; reports on damage.

Converters

FREQUENCY. Frequency-Changers, S. Neville. *Power Engr.*, vol. 26, no. 299, Feb. 1931, pp. 46-49. Characteristic types, limitations and operating features of synchronous, induction-synchronous and asynchronous frequency changers.

Dielectrics

Contribution to the Theory of Dielectrics, G. Gueben. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, vol. 11, no. 69, Feb. 1931, pp. 405-410. It is supposed that current in dielectric is due both to contribution of dipoles and to presence of ions; part due to each of these two elements is determined and formula is proposed for general expression of current in solid dielectric.

Modern Theories of Dielectrics, W. N. Stoops. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 183 and 185. Two of first questions asked about any new insulating material have to do with its dielectric constant and its power-factor; within recent years, understanding of these properties of dielectric has increased greatly; general discussion of modern conceptions is given.

Dynamometers

ELECTRIC. The Dynamo-Electric Machine as a Dynamometer, B. P. Haigh. *Engineering*, vol. 131, no. 3394, Jan. 30, 1931, pp. 129-131, 12 figs. Modifications required to enable standard dynamo or motor to measure torque in its shaft, and certain precautions that should be observed in order to obtain accurate results; examples installed in Engineering Laboratory of Royal Naval College, Greenwich, are illustrated.

Education

ENGINEERING. Some Facts about the Scholastic Achievements of Engineering Students, H. W. Miller and J. C. Palmer. *Jl. Eng. Education*, vol. 21, no. 5, Jan. 1931, pp. 371-383, 9 figs. Investigation of results accomplished by segregating high and low students in classes by themselves.

Electric Drive

CANALS. The Welland Ship Canal—XVII. *Engineering*, vol. 131, no. 3395, Feb. 6, 1931, pp. 166-169, 15 figs. partly on p. 176. Whole of machinery required for operation of canal is electrically driven; complete system of electric lighting is installed and master of controls, interlocking and signaling are all electrically operated; power is purchased from Hydro Electric Power Commission of Ontario, power being transmitted over canal transmission line and transformed in and distributed from substations; on canal power is used mainly for operation of locks and bridges, lighting and heating control houses and substations; details of electric equipment and insulation.

CEMENT PLANTS. Modernizing a Cement Works, S. Hopferwieser. *Brown Boveri Rev.*, vol. 18, no. 3, Mar. 1931, pp. 116-119, 11 figs. Various drives and equipment installed at S. A. des Ciments Portland de Lorraine, Strasbourg; by extensions and improvements made; daily production of plant was increased in this way from 160 tons to about 800 tons.

COAL HANDLING. The Use of Alternating Current for Handling Coal—I, R. F. Emerson. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, pp. 104-111, 12 figs. Conditions peculiar to handling of coal, coke and ashes, such as effect of these different kinds of dust on motor insulation and special precautions to be taken; handling of coal by coal towers, bridges and cranes, rotary-type car dumpers; equipment and performance characteristics.

STEEL PLANTS. An Electrified Steel Mill, R. H. Wright. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 146-149, 8 figs. Improvements completed last year in Alabama City plants of Gulf States Steel Co. make this one of most modern steel mills; 7000-hp. adjustable-speed d-c. reversing motor, capable of developing 19,000 hp. momentarily, drives 40-in. blooming mill; first installation of synchronous motors on roll mill; intermediate roll trains are driven by 2750-, 2100-, 1750- and 1300-hp. motors.

Electric Discharge

GLOW. On the Distribution of Space-potential in High Frequency Glow Discharg , D. Banerji and R. Ganguli. *Lond., Edinburgh, and Dublin Philosohpical Mag. and Jl. Science*, vol. 1, no. 69, Feb. 1931, pp. 410-422, 5 figs. Exploring collector method of Langmuir and Mott-Smith has been applied to study space-potential distribution, ionic concentration, current density, and average electronic velocity in case of high-frequency discharge through rarefied air and oxygen; it has been found that potential distribution is symmetrical about middle point of discharge-tube, both electrodes acting as cathodes in corresponding d. c. discharge.

Electric Equipment

DESIGN. Tendances actuelles dans l'équipment électrique des centrales (Present Trend in Design of Electric Powerplant Equipment), V. Olerin. *Union des Ingênieurs Sortis des Ecoles Speciales De Louvain—Bul. Technique*, no. 4, 1930, pp. 41-76, 23 figs. Development in high capacity electric powerplant and substation machinery and equipment in United States and Europe is reviewed and illustrated; wiring diagrams are given.

Electric Heating

The Heating of Buildings, D. J. Bolton. *Elec. Rev.*, vol. 108, no. 2777, Feb. 13, 1931, pp. 306-307. General considerations governing use of electricity for purpose; fuel costs of alternative systems; comparative efficiencies; capital expenditures; costs of operation; indirect advantages of electric heating; thermodynamic principles.

INDUSTRIAL. Industrial Electric Heating. *Elec. Engr. Australia and New Zealand*, vol. 7, no. 10, Jan. 15, 1931, pp. 365-369. Applications and advantages of electricity for industrial heating in which author points out that electricity competes successfully against other heating media on account of its advantages rather than its cost.

Electric Lines

GROUNDING. Earthing of E.H.T. Systems, J. Eccles. *Elec. Times*, vol. 79, no. 2050, Feb. 5, 1931, pp. 243-244, 3 figs. Practise of earthing e.h.t. transmission systems through tuned choke coils instead of through non-inductive resistances has been developed principally on continent and for certain systems it has indisputable advantages.

CALCULATION. Sinusoidal Currents in Linearly Tapered Loaded Transmission Lines, J. W. Arnold and P. F. Bechberger. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 2, Feb. 1931, pp. 305-310, 3 figs. Working formulas for calculation of input impedances and attenuation are obtained for transmission line in which resistance and inductance per unit length are linear functions of distance, and in which capacitance and leakance are constant; generalized functions depending on initial constants and rate of taper are introduced, in such way that formulas and functions are analogous to usual formulas and hyperbolic functions.

HIGH TENSION. Ueber ungleichmaessig verteilte Zusatzlast bei Hochspannungsleitungen mit Haengisolatoren (Unequally Distributed Additional Load in Electric High Tension Lines on Suspension Insulators), O. Strand. *Elektrotechnische Zeit.*, vol. 52, no. 10, Mar. 5, 1931, pp. 316-320, 6 figs. Method for calculation of all asymetric loading conditions for stranded conductors by which it is possible to determine irregularities in span, vertical load insulators, etc., in simple manner.

Electric Signs

NEON. A Short Analysis of the Neon Sign Situation, A. W. Murdock. *Elec. News*, vol. 40, no. 4, Feb. 15, 1931, pp. 49-50. As operating costs over 5-year period are only 25 per cent of incandescent signs large increase in their use may be expected.

Electrolysis

WATER PIPE. Why Prohibit Grounding of Telephone Cable Sheaths on Water Pipes, I. D. Van Giesen. *Water Works Eng.*, vol. 84, no. 3, Feb. 11, 1931, pp. 159-160 and 180 and 183, 6 figs. Report on experiments conducted by electrolysis engineer of Department of Water and Power, Los Angeles, Cal.; use and effects of a.c. and d.c. currents; dual nature of stress in charged conductor; joint use of poles causes trouble; noise reduced by grounding; investigation of noise arising from joint use of poles; effects of grounding; how ground is to be made. Before Am. Water Works Assn.

Furnaces

Les fours électriques a récupération aux usines citroen (Recuperative Electric Furnaces in the Citroen Plants). *Jl. du Four Electrique*, vol. 40, no. 1, Jan. 1931, pp. 11-13, 4 figs. Heat treatment equipment saving approximately 20 to 30 per cent of electric power over ordinary furnaces as usually employed in United States; two of this type of furnaces are installed in Citroen plant in Paris by Jean Aubé, in which parts of 500 cars produced in 24 hr. are handled; operation requires 4 men, against 10 men required by 12 old furnaces, which they replace.

HEAT TREATING. Electric Furnaces and Low-Temperature Treatments, J. E. Oram. *Metallurgia*, vol. 3, no. 15, Jan. 1931, pp. 94-96, 5 figs. Low-temperature heat-treatments offer additional scope to electric furnace; low operating and maintenance costs and ease of temperature control are associated with this type of equipment.

HIGH FREQUENCY. Hoegfrekvensugnen Ur Elektrisk Anlaeggningssynpunkt (High-Frequency Furnaces from Standpoint of Electric Engineers), J. Oesterberg. *Teknisk Tidskrift*, vol. 61, no. 1, Jan. 3, 1931, (Elektroteknik), pp. 8-12, 11 figs. General considerations in design of furnaces for melting of metal, and data on installations in Sweden built by AEG.

INDUCTION. Bisher unbekannte Badbewegungen bei Induktionsoefen (Heretofore Unknown Bath Movements in Induction Furnaces), E. F. Russ. *Giesserei*, vol. 18, no. 8, Feb. 20, 1931, pp. 165-166, 1 fig. Review of previous research on bath movements in induction furnaces, notably that of Hering and Northrup and formulation of pinch effect and Northrup effect; results of author's experiments, and conclusions based thereon.

LABORATORY. Beschreibung eines Zerreissofens (Tensile Testing Furnace), O. Holtschmidt. *Mitteilungen aus den Forschungsanstalten*, vol. 1, no. 2, Nov. 1930, pp. 40-44, 4 figs. Price 2.50 m. Requirements of laboratory furnace for testing influence of temperature on properties of steel, and description of electric furnace developed and perfected in course of eight years; elongation measurements.

Generators

ROTORS. Fatigue Tests of Model Turbo-Generator Rotors, R. E. Peterson. *Mech. Eng.*, vol. 53, no. 3, Mar. 1931, pp. 211-215, 10 figs. Results of tests of rotor end forgings to obtain data as to safety during operation; tests with fatigue loading only, and with superimposed centrifugal stressing.

STABILITY. Generator Stability Features Fifteen Mile Falls Development, R. Coe and H. R. Stewart. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 139-143, 9 figs. Generators in New England Power Association's 15 mile falls development are notable for several reasons; they are of new umbrella type which has but one guide and one thrust bearing, both located below rotor; to insure stability generators were built with especially low transient reactance, large flywheel effect special damper winding, and quick-response excitation system; electric and mechanical characteristics are discussed, notes on testing.

SYNCHRONIZATION. Measurement of the Load Angle of Synchronous Machinery, J. C. Prescott and E. W. Connon. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 410, Feb. 1931, pp. 281-289, 12 figs. Method of determining by direct measurement synchronizing power flowing to or from alternator for given angular displacement of rotor from normal running position; method was developed in connection with some experiments on natural free period of alternators, but results of measurements can be used to obtain effective reactance of machine and demagnetizing and cross magnetizing coefficients for armature field; experimental results are quoted.

WATERWHEEL. 20,000 Kva. Water Wheel Alternators. *Engineer*, vol. 151, no. 3971, Feb. 13, 1931, pp. 192-194, 9 figs. Large alternators forming initial generating plant of Waikaremoana hydroelectric power station of New Zealand constructed and installed by Metropolitan Vickers Electrical Co.; normal rating is 20,000 kva.; normally they are driven at 428 r.p.m. but are designed for overspeed of 85 per cent; current is generated at 11,000 volts and each generator feeds through its own bank of step-up transformers on to 110,000-volt busbars; lubrication is provided by low-pressure oil supply.

Water-Wheel Alternators; Trend of Development, F. Ruedenberg. *A EG Progress*, vol. 7, no. 1-2, Jan.-Feb. 1931, pp. 17-22, 11 figs. Meticulously prepared designs have given A.E.G. assurance that construction of much larger hydro-power alternators (over 100,000 kva.) can be tackled while retaining fundamental arrangements approved for so many years and applying constructional materials obtainable at present day.

High Head Impulse Unit With Unique Control. *Elec. News*, vol. 40, no. 5, Mar. 1, 1931, pp. 31-34, 3 figs. Vancouver Island Power Co.'s Jordan River plant now complete with fourth unit; unit is 15,000-kva., 6600-volt, 60-cycle three-phase English electric generator, driven at 300 r.p.m. by two tangential waterwheels, one mounted on each end of shaft and overhanging bearings; waterwheels are together rated at 18,000 b.hp.; more than 1¾ mi. of steel penstock required.

Humming

ELECTRIC LINES. Le Ronflement des lignes aériennes et les perturbations atmosphériques (Humming of Aerial Lines and Disturbances in Atmosphere), A. Noden. *Acadêmie des Sciences—Compie Rendus*, vol. 191, no. 20, Nov. 17, 1930, pp. 959-961; see also brief translated abstract in *Experimental Wireless*, vol. 8, no. 89, Feb. 1931, p. 91. Valuable meteorological information can be obtained from humming of aerial lines; two such lines, at right angles are installed at Biarritz observatory; humming, which as rule occurs in calm atmosphere, is attributed to electrostatic attractions provoked by successive small masses of highly charged air passing rapidly over line in direction at right angles to it.

Hydroelectric

EQUIPMENT. Some Outstanding Trends in Canadian Central Station Practise, D. Anderson. *Elec. News*, vol. 40, no. 4, Feb. 15, 1931, pp. 42-44, and 50, 5 figs. Tie-bank connections were constructed for interchange of power on Southern Canada and Shawinigan systems and on East Kootenay and Calgary Power systems; 8000 ft. river crossing was built to carry power from Falls River to Prince Rupert, B. C.; welded type generators have found broad application in new plants constructed; field of propeller runners was increased to 66 ft. head; notes on metal-clad switchgear, welded and umbrella-type generators, higher head propeller runners, long distance transmission spans.

PAPER MILLS. An Ideal Site Developed the High Falls Plant. *Elec. News*, vol. 40, no. 4, Feb. 15, 1931, pp. 39-42, 6 figs. James MacLaren Co. has filed plans with Dominion government for another development, of 120,000 ultimate hp. capacity with 200-ft. head at point farther down river between Buckingham and Masson; it is at latter town 25 miles below High Falls, that company has stepdown transformer station for its new large paper mill which went into operation last September; hydr electric plant and transmission lines are described.

Insulation

PAPER. Paper Applications in Electrical Industry, W. H. Anderson. *Paper Trade Jl.*, vol. 92, no. 7, Feb. 12, 1931, pp. 39-41. Paper before Tech. Assn. Pulp and Paper Industry, indexed in Engineering Index 1930, from Paper Mill, Dec. 27, 1930.

PHENOLIC. Electrical Materials Commonly Used—Laminated Phenolic Insulation, W. C. Hirsch. *Elec. Mfg.*, vol. 7, no. 2, Feb. 1931, pp. 57-59, 2 figs. Laminated phenol-resinoid sheets range in size up to about 39 by 47 in.; thicknesses range from 1/64 to 5 in.; tubes and rods come in lengths of 18, 24, 36, and 48 in., ranging in diameter from 1/8 to 12 in. with 1/32- to 1¼-in. wall thicknesses; rods range in diam. from 1/8 to 4 in.; there is almost no limit to variety of applications of this hard and tough material.

VARNISH. Insulating Varnishes, H. N. Bassett. *Elec. Times*, vol. 79, no. 2054, Mar. 5. 1931, pp. 433-434. Classification; solvents; impregnation and drying; examination and testing; other uses.

WOOD. Woods for Insulation, A. F. Dunton and A. W. Muir. *Elecn.*, vol. 106, no. 2750, Feb. 13, 1981, pp. 237-239, 6 figs. Varieties used; methods of impregnation; breakdown voltages of treated woods.

Lamps

GAS-FILLED. Gasfilled Lamps, A. E. Williams. *Elec. Rev.*, vol. 108, no. 2779, Feb. 27, 1931, pp. 371-372, 3 figs. Notes on chemical processes involved in their manufacture; arrangement of "gettering" apparatus; argon gas; gas pressure in lamp; chemical "getters."

GLOW. Low-Voltage Tube Lighting Available. *Elec. World*, vol. 97, no. 7, Feb. 14, 1931, p. 324, 1 fig. New era in commercial application of luminous tubes was forecasted in recent announcement by Claude Neon Lights, Inc. New York, of commercial production of units developed for general interior lighting on 110 volt and 220 volt service; rare gas tubes are now applicable to commercial, industrial and special residential lighting, and greatly increased range of color effects has been achieved.

Neon Tube Light and Factors Governing Its Life, R. R. Machlett. *Franklin Inst.—Jl.*, vol. 212, no. 3, Mar. 1931, pp. 319-326. Electrical characteristics; function of pressure; sputtering; life effect of electrode material and of pressure on life of tube.

Lighting

Calcul de l'éclairage par projecteurs (Calculation of Lighting by Pro-jectors), G. Beylon. *Electriciens*, vol. 47, no. 1509, Feb. 1, 1931, pp. 60-62, 1 fig. Calculation of projected light is simple in theory but difficult and in exact when location of lighting equipment is close to surface to be lighted, simple numerical analysis for various cases is given.

SERIES. Standard and Proposed Cutout Designs for Series Street-Lighting Circuits, H. E. Butler. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, pp. 112-114, 2 figs. Inspection of designs, together with considerations showing that much study has been given to problem of developing best type of film cut-out (at present special-oxide form) for use on either low or high voltage series street-lighting circuits; cut-outs of new designs, special-oxide disk type and electromagnetic type will function satisfactorily at low-voltage rating.

Lightning

ELECTRIC LINES. Der Blitzschlag in Hochspannungsanlagen und seine Folgen (Lightning Striking in High Tension Lines and Consequences Thereof), E. Flegler. *Elektrotechnische Zeit.*, vol. 52, no. 5, Jan. 29, 1931, pp. 129-133, 4 figs. Form of resulting waves; requirements of protective equipment against excessive voltages are pointed out.

Meters

WATTHOUR. Checking Load and Power Factor from Watthour Meter Readings, M. A. Faucett and J. O. Kraehenbuehl. *Factory and Indus. Mgmt.*, vol. 81, no. 3, Mar. 1931, pp. 427-428. Determination of corrected power and power factor shown by example using G. E. meter of D-7 type, 100 amperes, three-phase and 220 volts.

Motors

DESIGN. Sub-Synchronous and Standard-Speed Motors. *Product Eng.*, vol. 2, no. 2, Feb. 1931, pp. 67-70, 8 figs. Advantages of sub-synchronous motors which run at 200 r.p.m. or 600; practical discussion of proper methods in selection of motor for clocks, recording instruments and light power requirements. (Continuation of serial.)

DIRECT-CURRENT. Berechnung von Gleichstrommotoren nach preiswirtschaftlichen Gesichtspunkten (Calculation of D-C. Motors According to Economic Viewpoints as to Costs), R. Hofmann. *Elektrotechnik und Maschinenbau*, vol. 49, no. 5, Feb. 1, 1931, pp. 81-85, 1 fig. Determination of favorable pole and yoke inductions and of most advantageous magnetic flux; practical example is given.

FRACTIONAL HORSEPOWER. Closed Iron Ring Motor. *Elec. Times*, vol. 79, no. 2051, Feb. 12, 1931, pp. 282-284, 7 figs. Motor described presents some novel features in design and operates on entirely new principle; original invention was made by J. Zetsche, of Germany, in attempt to produce gramophone motor having superior characteristics to those of existing designs.

Modernize Wiring and Motors for Better Voltage Regulation, L. L. Elden. *Elec. World*, vol. 97, no. 9, Feb. 28, 1931, pp. 416-417. Failure to recognize merits of new developments in motor design and importance of more adequate wiring will result in many cases in poor service and economic losses which cannot be compensated for otherwise; figures on sources of poor regulation point to conditions which should no longer be overlooked by progressive power companies; test data on 387 motors causing lighting fluctuations; motor-starting currents and overloaded wiring causing complaints.

INDUCTION. Moteur asynchrone auto-compensé a démarrage automatique (Self Compensated Induction Motor for Automatic Starting), P. Letrilliart and P. Fourquet. *Revue Générale de l'Electricité*, vol. 29, no. 5, Jan. 31, 1931, pp. 163-178, 15 figs. Mathematical analysis of principles, characteristics and performance of motor with 2 windings on rotor and 2 on stator.

OSCILLATING ARMATURE. Ein neuer Wechselstrom-Kleinmotor (Novel Fractional Horse Power A. C. Motor), C. Kuehnel. *Elektrotechnische Zeit.*, vol. 52, no. 9, Feb. 26, 1931, pp. 267-268, 3 figs. Oscillating armature motor by which armature oscillates synchronously which each half cycle around axle and then are converted into rotating motion is described; practical applications are discussed.

STARTING. Methodes de démarrage des moteurs asynchrones diphasés a cage d'écureuil (Methods for Starting of Two-phase Induction Motors with Squirrel Cage Rotor), Marre. *Electriciens*, vol. 47, no. 1510, Feb. 15, 1931, pp. 74-76, 6 figs. Various hook ups, their features and analysis.

TESTING. Eine neue Methode zur kuenstlichen Belastung von Induktionsmotoren (New Method for Artificial Loading of Induction Motors), A. M. Bamdas. *Elektrotechnik und Maschinenbau*, vol. 49, no. 5, Feb. 1, 1931, pp. 86-88, 2 figs. Method developed by author and S. B. Eliaschewitz by which stator and rotor are connected to separate networks.

Networks

DESIGN. Rural Electrification, A. Ekstrom and V. Ekstrom. *Elecn.*, vol. 106, no. 2753, Mar. 6, 1931, pp. 357-359, 2 figs. Simple method of calculating most economical cross section of conductor for given maximum permissible drop in voltage.

STABILITY. Power-system Stability—II, R. D. Booth and O. G. C. Dahl. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, pp. 131-141, 10 figs. Notes on generator design and reactance; line and transformer reactances; synchronous condenser size and reactance; load characteristics; voltage regulator and exciter characteristics; governor action; inertia of rotating machines; damper windings and their effects; effect of different grounding systems; effect of circuit-breaker operation; determination of transient operating characteristics.

Photoelectric

AMPLIFIERS. Ueber die Verstaerkung von Photozellenstroemen (Amplification of Current from Photoelectric Cells), H. Simon. *Elektrotechnische Zeit.*, vol. 52, no. 9, Feb. 26, 1931, pp. 264-266, 10 figs. Various types are described and possibilities of application are discussed.

COLOR MEASUREMENT. Photo-Electric Cell Has Definite Place in Color Measurement, W. M. Scott. *Textile World*, vol. 79, no. 8, Feb. 21, 1931, pp. 886-889, 4 figs. Uses, limitations and future possibilities of photoelectric cell; determination of light energy; recent developments.

Power

DOMESTIC. Poughkeepsie Plan Quintuples Domestic Usage, Triples Revenue, A. M. Perry. *Elec. World*, vol. 97, no. 10, Mar. 7, 1931, pp. 444-449, 4 figs. Domestic use of electricity has been nearly multiplied by five and revenue increased three times what it was just before "full-use" electric home plan was inaugurated by Central Hudson Gas & Electric Corp.; customers have changed from limited use of electric conveniences to "full-use" and obtained nearly five times as much energy as formerly for only half unit price, including amortization of equipment cost; analysis based on one year's experience of plan is given.

INDUSTRIAL PLANTS. Bringing Electric Power into the Small Plant, R. H. Rogers. *South Power Jl.*, vol. 49, no. 2, Feb. 1931, pp. 99-103, 7 figs. Accumulated experience of years in industrial electrification has determined certain practises and methods as being most successful from standpoints of procedures of power, insurance underwriters, and consumer; meter and lighting; practical application of electric drive; electric motor control.

Power Factor

Power Factor Determination, C. F. Dalziel. *Elec. West.*, vol. 66, no. 3, Mar. 1, 1931, pp. 124-126, 5 figs. Practical methods of measuring power factor and verifying reverse power relay connections in three-phase power systems. (To be continued.)

Power Plants

Steam and Diesel Units Combine to Give Low Over-all Power Costs, E. J. Kates. *South. Power Jl.*, vol. 49, no. 2, Feb. 1931, pp. 52-54, 2 figs. In power plants serving dual needs of power and steam, Diesel engine indicated as companion unit to steam prime mover, when power demand exceeds steam or heat demand; tabular results of comparative power cost studies for large department store.

Radio

AMPLIFIERS. Maximum Undistorted Power Output, G. Smiley. *Radio Eng.*, vol. 11, no. 2, Feb. 1931, pp. 36-39 and 50, 7 figs. Engineering analysis of factors determining amplifier design and performance.

CONDENSER LOSSES. The Losses in Variable Air Condensers, W. H. F. Griffiths. *Experimental Wireless*, vol. 8, no. 90, Mar. 1931, pp. 124-126, 5 figs. Method of analysis is amplified by omitting all reference to voltage or current, reasoning being based merely upon impedance triangle of capacity and resistance in series which gives well known simple expression for power factor, to high degree of approximation.

CONDENSER TESTING. By-Pass Condenser Production Test Equipment, F. W. Stellwagon. *Electronics*, vol. 2, no. 2, Feb. 1931, pp. 504-505, 5 figs. Grebe Co. uses by-pass condenser test apparatus capable of completely testing over 500 by-pass condenser units per hour; tests include ten-second test at 200 per cent of rated d-c. voltage, discharging of charged condensers, testing insulation between condenser terminals and container, and checking capacity of four condenser sections.

DISTORTION. An Analysis of Distortion in Resistance Amplification, E. B. Moullin. *Experimental Wireless*, vol. 8, no. 90, Mar. 1931, pp. 118-123, 4 figs. Method of predicting from static characteristic output of resistance coupled amplifier; certain form of equation is assumed for characteristic and this leads to simple rules for deducting fractional amplitudes of second and third harmonic currents.

RECEIVER TESTING. Special Instruments for Radio Receiver Production Testing, R. P. Glove. *Electronics*, vol. 2, no. 2, Feb. 1931, pp. 500-501, 4 figs. Notes on adaptation of Wheatstone bridge; condenser test equipment; visual test apparatus; production testing of audio amplifiers; loud speaker testing.

TUNING. Selectivity and Response, E. E. Wright. *Experimental Wireless*, vol. 8, n . 90, Mar. 1931, pp. 133-134, 1 fig. Attempt to find from theoretical reasoning response of selectivity tuned circuit to steadily modulated wave.

Railroad

ELECTRIFICATION. West Side Freight Electrification of New York Central Railroad, W. J. Hedley and J. F. Walker. *Gen. Elec. Rev.*, vol. 34, no. 3, Mar. 1931, pp. 165-169. 7 figs. West side improvement involves, in addition to electrification work being carried out by Railroad Company, variety of other changes which are being done jointly with City of New York, including elimination of tracks from streets and provision of space for high speed traffic roadway from Canal Street and West Street to 79th Street and Riverside Drive; notes on road freight locomotives; switching locomotives; operating conditions.

The Reading-Philadelphia Suburban Electrification, G. I. Wright and A. I. Totten. *Gen. Elec. Rev.*, vol. 34, no. 3, Mar. 1931, pp. 173-179, 13 figs. Enlargement of service to include through passenger and freight traffic; single-phase, 25-cycle, 12/36-kv., three-wire system, as finally decided upon, consists essentially of frequency-changer station at Wayne Junction to be owned by Philadelphia Electric Company; initial peak load, in suburban zone, will approximate 9000 kw. or about 13,000 kva.; frequency-changer station; distribution system; multiple-unit cars; traction motors; control and auxiliary equipment, are discussed.

SIGNALING. Automatic Block Signaling on the Canadian Pacific Railway, A. K. Kidd. *Elec. News*, vol. 40, no. 5, Mar. 1, 1931, pp. 39, 40 and 42, 3 figs. Semaphores are being replaced with colored light signals which may have effective range from 3000 to 4000 ft. in bright sunlight; most recent development in signaling is centralized traffic control.

D. and H. Handles Four Ends of Double Track by Centralized Control. *Ry. Age*, vol. 90, no. 8, Feb. 21, 1931, pp. 411-412, 3 figs. Installation between Center Village, New York, and Lanesboro, Pa. has solved operating problem on two short sections of single track and permits closing of four offices; operating characteristics; outside construction; track and signal plan of centralized traffic control territory.

Substations

High Power Mercury Arc Rectifiers, N. von Kotschubey. *Elec. Times*, vol. 79, no. 2053, Feb. 26, 1931, pp. 377-380, 6 figs. Description of substation plant of new South Wales government railways and tramway system Sydney; adoption of mercury arc rectifiers not only simplified service conditions of N.S.W. Government railway substations, and reduced operation costs by increasing over-all efficiency of plants, but also considerably lowered initial cost of substations; tables showing how costs of three 1500-kw. 1500-v. rotary converter units at Belmore compare with those of identical rectifier substation at Epping.

Rate Making

POWER INDUSTRY. Electric Power Supply in the Limelight, L. R. Nash. *Stone and Webster Jl.*, vol. 49, no. 2, Feb. 1931, pp. 84-92. Public utilities supply more than two-thirds of electricity used; electric service highly developed in South; domestic and rural service; casual service rates below cost, service charge; rural rates; further rate practises; electric rates lower than general price level.

The Domestic Tariff, C. F. Mounsdon. *Elec. Rev.*, vol. 108, no. 2776, Feb. 6, 1931, pp. 232-233. It is claimed that practical difficulties experienced in use of any single-basis two-part tariff would be obviated by introduction of composite basis for fixed charge.

Relays

PROTECTIVE. Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 172-178, 16 figs. Overcurrent relays for generator differential protection; ratio-differential relays for generator protection; overspeed protection of generators; generator field protection; undervoltage time-delay protection for motors; synchronous condenser protection; synchronous-converter protection; motor-generator protection; protection of frequency-changer sets.

Safety Devices

ELECTRIC APPLIANCES. The Safety of Domestic Electrical Appliances, G. W. Stubbings. *Elec. Engr. Australia and New Zealand*, vol. 7, no. 10, Jan. 15, 1931, pp. 373-374. Various methods that are employed with view to increasing safety, viz., earthing, construction of insulating material, low working voltage, and use of leakage relays; author points out that each has certain shortcomings, and therefore further research into safety methods is necessary.

Ship

ELECTRIC EQUIPMENT. The Electrical Equipment of Ships, J. E. Allen, vol. 131, no. 3395, Feb. 6, 1931, p. 191. Difference in practise between electricity at sea and on land; totally enclosed motors, specially designed to prevent entry and deteriorating effects of moisture, oily vapor, salt-laden air and seawater; use of contactors for making and breaking first step of starting resistance; deck machinery; rubber-insulated cables. Before Inst. Mar. Engrs.

Starters

MOTOR. Small A-C. Motor Starters, J. P. S. Pillans. *Elec. Rev.*, vol. 108, no. 2779, Feb. 27, 1931, p. 369. With view to providing all desirable operation and protection features at moderate cost author suggests modification of simple switch-fuse.

Substations

HEATING. Electric Heat for Substation and Office Buildings, P. Sporn. *Elec. World*, vol. 97, no. 10, Mar. 7, 1931, pp. 463-464, 3 figs. Number of substations and office buildings on properties of various subsidiaries of American Gas & Electric Co. have been equipped with electric storage type heating systems; in Hall system employed in all these installations water is heated by direct contact with totally inclosed immersion units; general basis on which to make calculations for justifying or disproving economic feasibility of electric heating, is outlined.

Switches

VACUUM TUBE. A Vacuum-tube Time Switch. W. K. Kearsley. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, pp. 128-129, 2 figs. Type of equipment described is outcome of developmental work to produce time switch that has no moving parts; in it, vacuum tubes and other static electrical equipment accomplish what is ordinarily considered to be functions of mechanisms and motion.

Switchgear

LOSSES. Eddy Current Losses in Heavy Current Switchgear—I, J. E. Shaw. *World Power*, vol. 15, no. 86, Feb. 1931, pp. 109-113, 7 figs. Measurement of iron loss in large oil switch tanks and switch tops with 5000 amps. flowing in loop conductor; methods adopted for obtaining conditions similar to those in practise; from results obtained on various sizes of switch tanks and switch tops empirical formulas are derived whereby losses may be estimated in any desired case to within 10 per cent and thence temperature rises estimated. (To be continued.)

Telephone

CARRIER CURRENT. Practising Economy in Carrier Operation, F. D. Dommerque. *Telephone Engr.*, vol. 35, no. 2, Feb. 1931, pp. 33-34, 1 fig. Loading coils are not practical on long distance lines when repeaters are introduced, but economical for straight toll lines and cables. (Continuation of serial.)

Transformers

DESIGN. Design Features of World's Largest Transformers, H. L. Cole and F. J. Vogel. *Elec. World*, vol. 97, no. 8, Feb. 21, 1931, pp. 374-377, 5 figs. World's largest power transformers; are located at Roseland, N. J., switching station of Public Service Electric & Gas Company; they form two 90,000-kva. transformer banks, with one spare unit stepping from 220,000 Y volts to 132,000 Y volts (or vice versa), with 60,000-kva., 11,000-volt delta-connected tertiary winding for supplying synchronous condensers; they are oil insulated, self cooled by radiators, single-phase units; 132,000-volt winding is made up of two separate windings, each of one-half capacity, for connection to double bus transmission system.

Transformer Developments. *World Power*, vol. 15, no. 86, Feb. 1931, pp. 130 and 133-134, 4 figs. Design and operating characteristics of "grid" transformer under construction for Central Electricity Board; record of export work carried out by British Electric Transformer Co., Ltd., in recent years.

INSTRUMENT. Ueber die Anforderungen an Stromwandler in Kraftwerken (Requirements of Current Transformers in Power Plants), G. Keinath. *Elektrizitaetswirtschaft*, vol. 30, no. 3, Feb. 1931, pp. 60-68, 9 figs. Summary of developments regarding properties, degree of exactness; secondary output; rating, class and current overloading capacity, test voltage and operating voltage, construction, system of insulation, thermal strength; excessive current rating, dynamic strength, surge proofness.

Calculation of Instrument Transformer Burdens, T. A. Hammond. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, pp. 115-126, 19 figs. Significance of burdens; effect of burden magnitude on accuracy; errors from secondary leads; single-phase burdens; effect of secondary interconnections.

Transients

An Experimental Method of Studying Transient Phenomena, H. M. Turner. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 2, Feb. 1931, pp. 268-281, 14 figs. Description of experimental method of studying transient phenomena which, by repeating phenomena synchronously enables one to observe it on screen of oscillograph as long as desired; method is based upon use of transient visualizer.

REFLECTION. Zur Metallreflexion (Metallic Reflection), J. Zahradnicek. *Zeit. fuer Physik*, vol. 65, no. 11-12, Nov. 14, 1930, pp. 814-823; see also brief translated abstract in *Experimental Wireless*, vol. 8, no. 89, Feb. 1931, p. 88. Theory of phenomena of reflection of plane; linearly polarized electromagnetic wave at metallic surface is developed from Maxwell's equations and appropriate boundary conditions; formulas for refractive index and index of absorption are given which are more general than those deduced by Drude for normally incident wave; suggestions for experiment at different angles of incidence are made and tables given.

TESTING. High-Voltage Surge Testing, F. D. Fielder. *Elec. Jl.*, vol. 28, no. 3, Mar. 1931, pp. 161-164, 7 figs. Oscillograph would have limited value without auxiliary circuits and devices which make it integral part of testing circuit; timing system must be available to sweep beam across film at proper instant and at known speed of one to sixty mi. per sec.; test surges must be reduced without distortion to few hundred volts for measurement; oscillograph must be synchronized with surge generator to within fraction of microsecond.

Trolleys

TRACKLESS. The Modern Trolley Bus as a Central Station Load Builder, C. A. Burleson. *Gen. Elec. Rev.*, vol. 34, no. 2, Feb. 1931, p. 130, 1 fig. Advantages of trolley bus as compared with street car are lower investment; elimination of track and paving charges; curb loading and unloading; flexibility in traffic; quiter operation; faster schedules; as compared with gas bus: lower operating cost; unlimited power supply; higher schedule speeds; better lighting and heating; quieter operation; absences of fumes; less fire hazard; cost of power is low and stable.

Maintenance and Operating Factors of Trolley Buses, G. W. Wilson. *Elec. Traction*, vol. 27, no. 2, Feb. 1931, pp. 79-81, 2 figs. Operating and maintenance costs compared and methods employed to eliminate various difficulties in service; solving braking difficulties; acceleration and distance curves showing relative performance of trolley buses and gas buses. Before Assn. Equipment Men, Southern Properties.

Vacuum Tubes

CATHODE RAY. Further Advances in the Technique of the Braun Tube, M. von Ardenne. *Experimental Wireless*, vol. 8, no. 90, Mar. 1931, pp. 127-129, 4 figs. Cathode-ray tube for photographic recording, with new small type for visual observation is described; complete circuit of new cathode-ray equipment is given.

DETECTOR. High Level Plate Circuit Rectification, J. R. Nelson. *Electronics*, vol. 2, no. 3, Mar. 1931, pp. 550-551, 3 figs. Experimental procedure for attacking problem of plate rectification with large input voltages is receiving considerable attention at present; necessary experimentally determined curves may be obtained very easily so that anyone with measurable a-c. voltages and fairly accurate d-c. milliammeter may plot his own rectification characteristics for resistance load; characteristics curves of 227 tubes are given.

RECTIFIER. Zur Theorie eines Gleichrichters mit fallender, hyperbelformiger Kennlinie (Theory of Rectifier with Decreasing Hyperbolic Characteristics), O. Stierstadt. *Elektrische Nachrichten-Technik*, vol. 8, no. 1, Jan. 1931, pp. 31-38, 7 figs. Performance of rectifier tube is mathematically analyzed.

Welding

ARC. Arc Welding in 1931, J. F. Lincoln. *Boiler Maker*, Feb. 1931, pp. 50-51, 1 fig. Review of developments in arc welding during past year; equipment and processes; arc welding in structural engineering.

Arc Welds Cut Repair and Maintenance Bills, B. S. Havens. *Mill and Factory Illustrated*, vol. 8, no. 3, Mar. 1931, pp. 40-43, 14 figs. Examples of different applications. (To be continued).

ELECTRODES. Die Untersuchung von Elektroden fuer die Lichtbogenschweissung (Studies of Electrodes for Arc Welding), S. Sandelowsky. *Elektroschweissung*, vol. 2, no. 3, Mar. 1931, pp. 48-52, 15 figs. Strength of weld; texture of weld; shrinkage and stresses; economy. (Concluded.)

BRIDGES. Bemerkenswerte Schweissarbeiten an einer Eisenbahnbruecke (Welding of Railroad Bridge), E. Fromme. *Elektroschweissung*, vol. 2, no. 2, Feb. 1931, pp. 35-36, 4 figs. Modernization and making suitable for modern train traffic of 2500-m. long Moerdyk Bridge, in Holland, by electrically welded movable supports.

CAST IRON. The Use of Pure Iron Electrodes for Welding Cast Iron, H. D. Lloyd and J. S. G. Primrose. *Welding Jl.*, vol. 28, no. 328, Jan. 1931, pp. 18-22, 8 figs. Advantages of pure iron electrodes in making bed plate and repair electric motor casings; microphotographs illustrate burnt on weld in cast iron; phosphoric cast iron welded with soft pure iron.

MONEL METAL. Some Practical Notes on Welding Monel Metal. *Machy. (Lond.)*, vol. 37, no. 960, Mar. 5, 1931, pp. 733-734, 3 figs. Properties and use of monel metal with data on welding procedure; advantages of metallic arc welding of castings.

PIPE LINES. Pipe Line Welding, W. T. Graham. *Welding Engr.*, vol. 16, no. 2, Feb. 1931, pp. 42-44, 4 figs. Methods of preparing and welding of pipe developed by A. O. Smith Corporation; eight generator gangs consisting of foreman, mechanic and nine welders (one spare man) will produce average of 220, 10-in. weld, or 175, 16-in. welds or 132, 20-in. welds, or 110, 24-in. welds per 9-hr. day.

PRESSURE VESSELS. Welding Plates and Pressure Vessels, P. R. Hawthrone. *Welding*, vol. 2, no. 2, Feb. 1931, pp. 89-92, 5 figs. Tests show that by use of proper welding process, procedure control and method of annealing, welded vessels are made stronger than riveted ones.

Wiring

BUILDINGS. Vertical Distribution in World's Tallest Structure, J. A. Walsh. *Elec. World*, vol. 97, no. 7, Feb. 14, 1931, pp. 328-334, 10 figs. Empire State Building has frontage of 200 ft. on Fifth Avenue and 420 ft. on both 33d and 34th streets; gross floor area in 85 stories is 2,800,000 sq. ft. and rental area is slightly under 2,000,000 sq. ft.; 85th floor is 85 by 135 ft.; estimated connected load is 6000 kw. for lighting and 9600 hp. for power services; this estimate for connected lighting load was based on assumption of 6 amp. per ultimate lighting circuit; details of installation are given.

Industrial Notes

Anaconda Acquires Cable Accessories.—The Cable Accessories Corporation, formerly of Pittsburgh, and purchased by the Anaconda Wire & Cable Company, has been moved to the Hastings-on-Hudson, N. Y., plant, and is now operating to provide a complete cable service, including potheads, junction boxes, insulating compounds, jointing and miscellaneous materials.

Lincoln Electric Promotes George G. Landis.—According to a recent announcement, the Lincoln Electric Company, Cleveland, manufacturers of "Linc-Weld" motors and "Stable-Arc" welders, has advanced George G. Landis to the position of chief engineer. He has been with the company eight years. Many of the patents held by his employers, both on arc-welding equipment and electric motors, are the result of his work.

The Ohio Brass Company, Mansfield, Ohio, announces receipt of a contract from the Pennsylvania Water and Power Company covering all suspension insulators and hardware for its new 220-kv. transmission line connecting the Safe Harbor power development and Baltimore. This line, one of the most important in the system operated by Pennsylvania Water and Power Company, will serve Baltimore's industries.

Foster Wheeler Enters Boiler Industry.—With the acquisition of the plant and business of the D. Connelly Boiler Company, of Cleveland, the Foster Wheeler Corporation announces that it is prepared to furnish all types of boilers in the entire range of sizes and pressures. The Connelly Company was established more than fifty years ago. The Foster Wheeler Corporation has been supplying complete steam generators for some time, and has produced the various parts in its own works, with the exception of the boiler proper.

Inca Moves Eastern Office.—The Inca Manufacturing Division of the National Electric Products Corporation, has moved its eastern office from Newark, N. J., to 233 Broadway, New York. The new office, which includes both sales and service organizations, is under the direct supervision of Paul Stouffer. The main plant and general office are located in Fort Wayne, Ind., where a complete line of magnet wire and coils for the radio and electrical industries is manufactured. The eastern warehouse and coil winding department will continue to be maintained.

New Small Motors.—The Century Electric Company, St. Louis, announces a new line of fractional horsepower motors having mounting dimensions interchangeable,—in repulsion-start induction single-phase, split-phase single-phase, squirrel cage induction three-phase, and direct-current types. The bearing brackets of this design offer unusual protection against falling objects, dirt, or dripping water. The motors have rolled steel frames, welded steel feet, slotted for belt adjustment, and bearings machined from phosphor bronze castings.

New Underground Cable.—A new underground cable, known as "Flexlay," has been designed and is being manufactured by the National Electric Products Corporation, Pittsburgh. It is a flexible, highly insulated underground wiring system and is produced in three different types: non-metallic, semi-metallic and full-metallic which is better known as Parkway Cable. Flexlay may be laid in open trench without damage from abrasive handling, eliminating the use of clay or fibre ducts. It is so constructed as to adequately resist the action of soil textures, soil acids and prevailing moisture contents.

Large Turbine Order to Westinghouse.—The Public Service Electric and Gas Company at Newark, New Jersey, has recently awarded the Westinghouse Electric & Manufacturing Company an order for a 75,000 kw., 60 cycle, single-cylinder steam turbine-generator unit to be installed as the No. 6 steam unit at the Kearny generating station and which will bring the capacity in this station up to approximately 290,000 kw. The new unit will receive part of its steam from the mercury vapor condensers serving the 20,000 kw. G. E. mercury-vapor unit recently ordered from the General Electric Company.

In addition to the above the Public Service Electric and Gas Company has also ordered an 18,000 kw., high pressure, 60-cycle Westinghouse turbine unit for the Burlington generating station, to operate in connection with new boiler equipment on 650 pounds. With the addition of this new high-pressure turbine, the Burlington station is being remade into a most economical generating station and will be capable of developing approximately 55,000 kw. The approximate value of the two steam turbine units ordered from the Westinghouse Electric and Manufacturing Company is $1,250,000.

C. S. Knight, Jr., manager of the electrical and wire rope sales department of the American Steel & Wire Company, Chicago, died recently at the Worcester (Mass.) office of the company. Mr. Knight was 66 years old and a native of Worcester.

Trade Literature

Pole Top Switches.—Bulletin 36, 4 pp. Describes Pacific Electric type PS-1 pole top switches for light branch line construction where very moderate loads are to be controlled. Pacific Electric Manufacturing Corp., 5815 Third Street, San Francisco.

Lightning Arresters.—Booklets 2 and 3, 12 and 8 pp., respectively. Describe the construction and operation of crystal valve lightning arresters. Electric Service Supplies Company, 17th & Cambria Streets, Philadelphia.

Load Testing Set.—Bulletin, 2 pp. Describes a load testing set for measuring current without interruption to service. The complete equipment consists of a newly designed, highly efficient split-core current transformer, and a Weston ammeter, complete with connecting cable and plugging device. The entire equipment, with carrying case, weighs ten pounds. Electrical Engineering Sales Company, Los Angeles and San Francisco.

Illumination.—Bulletin A-1204, 24 pp., "Banishing the Twilight Zone from Modern Buildings." A discussion of present-day principles and practise in the interior lighting of modern buildings. Bulletin A-1206, 32 pp., "Bringing Cities Out of the Twilight Zone." A discussion of modern street lighting, presenting reasons and methods for providing well illuminated cities. Bulletin A-1208, 24 pp., "Skylines Beyond Twilight Zone." Discusses modern principles and practise in floodlighting. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Carbon Brush Manual.—Catalog B-131, 24 pp. This book differs from the ordinary carbon brush catalog, being designed to simplify the selection and specification of carbon and metal-graphite brushes. The new shunt nomenclature of the National Electrical Manufacturers Association has been adopted. The essential details for a complete brush specification are listed and discussed in the sequence which has been found most convenient. Tables of physical characteristics have been omitted. Instead, a cross index of grades and their applications simplifies the selection of a suitable grade for any service. Examples illustrate the manner in which the composite specification for a brush is derived and the price computed. National Carbon Company, Inc., Cleveland.

R. M. STANLEY (F '23) in collaboration with C. T. Sinclair (M '29) describes the application of the network idea to medium- and low-load areas in the vicinity of Pittsburgh. *(See page 400.)*

ELECTRIC SHOCKS which do not involve the brain, respiratory nerves, or spinal cord seldom jeopardize life in animal organisms according to experimental findings discussed by W. B. Kouwenhoven (M '22) and O. R. Langworthy of Johns Hopkins University, Baltimore. *(See page 406.)*

EDWARD DEAN ADAMS, Associate of the Institute, Edison Pioneer, and energetic leader in engineering, financial, and philanthropic undertakings answers the Last Call, largely as a result of a recent automobile accident. *(See page 452.)*

SOUTHERN HOSPITALITY and the beauties of the Carolina mountains, often extolled by President Lee, should combine to attract many to the Institute's summer convention at the Grove Park Inn, Asheville, N. C. Incidentally there is offered a splendid technical program and, of course, the annual Mershon Trophy golf tournament. *(See page 440.)*

BETWEEN SYMPOSIA on noise and on lightning, the Rochester, N. Y., meeting of the North Eastern District enjoyed rather an animated program. In this issue there may be found a complete news story of the meeting and also a summary of some of the more pertinent discussions. *(See pages 441 and 445.)*

CONCERTED cooperative attack upon the central problems presented in present noise studies and investigations is being sought as an inter-society activity. Delegates attending a special joint meeting at Rochester, N. Y., attempted to reach common ground and succeeded in agreeing upon a statement of three fundamental questions. *(See page 443.)*

EDISON BUST was presented May 7 to the German Museum at Munich with fitting ceremony. *(See page 446.)*

PACIFIC COAST convention committee has arranged for extension of special rates at Tahoe Tavern, Lake Tahoe, California, as an aid to those who will spend their vacation there in connection with the convention. *(See page 449.)*

DR. CHARLES F. SCOTT, past-president of the Institute and long-time head of the electrical engineering department of Yale University, New Haven, Conn., is planning to retire. R. E. Doherty, formerly G. E. consulting engineer, has been appointed as his associate; will succeed him upon his retirement. *(See page 450.)*

STUDENTS participated actively in the Rochester, N. Y., district meeting; presented several interesting papers. *(See page 444.)*

FUTURE MEETINGS

of the

American Institute of Electrical Engineers

Place	*Dates*	*Nature*	*Latest Date for Receipt of Manuscripts*
Asheville, N. C.	June 22-26, 1931	Summer Convention	(Closed)
Lake Tahoe, Calif.	Aug. 25-28, 1931	Pacific Coast Convention	(Closed)
Kansas City, Mo.	Oct. 22-24, 1931	District Meeting	July 22, 1931
New York, N. Y.	Jan. 25-29, 1932	Winter Convention	Oct. 26, 1931
Milwaukee, Wis.	March 14-16, 1932	District Meeting	Dec. 14, 1931
Providence, R. I.	May - 1932	District Meeting	Feb. - 1932

NOTE: Members who are contemplating submitting papers for presentation at any of the above meetings should communicate promptly with Institute headquarters, 33 West 39th Street, New York, N. Y., so that their papers may be docketed for consideration by the Meetings and Papers Committee, as programs for all meetings are formulated several months in advance. Upon receipt of this notification, Institute headquarters will mail to each prospective author information in regard to the Institute's rules relating to the preparation of manuscript and illustrations.

The Primary Network for Medium-Load Areas

As a result of the noteworthy economic and operating success of the secondary a-c. network the same principle now is proposed for relatively high-voltage primary systems. Based upon economic studies of two Pittsburgh residential areas one primary network now is under construction there and a second all planned. Major details involved are given here and ten distinct advantages are enumerated.

By
R. M. STANLEY — Byllesby Engineering & Management Corporation
Fellow A. I. E. E

C. T. SINCLAIR — Byllesby Engineering & Management Corporation
Member A. I. E. E.

A NETWORK may be said to exist wherever the secondaries of two or more transformer banks not at the same location are connected in parallel to supply a common load. This definition is applicable to either high- or low-voltage systems. In this discussion a new design of primary network is considered which combines the principle of interconnecting 4-kv. mains and certain principles common to the design of secondary network, and which is fed directly at load-transmission voltage.

Generally speaking, the comparable characteristics of the older radial primary distribution system and the new primary network are as revealed in Fig. 1 and in Table I.

TABLE I—ELEMENTS OF A PRIMARY SYSTEM

Radial	Network
1. Transmission feeders from source of supply to substation	1. Transmission feeders from source of supply to substation
2. The substation	2. The transformers and switches
3. The distribution feeders	3. The primary mains
4. The mains	

From these it may be seen that the elements of the two systems are the same except for the elimination of primary feeders in the network design—an important item, but only one of several which permit a saving in initial cost as compared with the radial system.

In the typical radial system (Fig. 1) the substation is located of course as nearly as possible at the center of the expected load and each feeder terminates at its approximate load center. In the typical primary network of Fig. 1 the transformer capacity required for the entire area is distributed, each transformer at an intersection of primary mains and each intersection group constituting a unit, including regulators on transformer secondaries where and if required. Similar to the principle of secondary networks, it is desirable that the transmission supply to a given area comprise three or more feeders in order to reduce the spare capacity required to accommodate the possible loss of a feeder.

Fig. 2. Radial versus network system for an area having a load density of 2,100 kva. per sq. mi.

COMPARATIVE COST ESTIMATES FOR AREA OF 2,100 KVA. PER SQ. MI.

To secure practical working data revealing the actual relative economies of the two systems, two different areas in the Pittsburgh district were studied exhaustively. Load growth in both areas required early attention to increased distribution capacity, and these comparative studies involved consideration of existing facilities as well as required extensions.

The initial study covered a residential section known as Squirrel Hill, which includes a few apartment houses and a small business district but no industrial load of any character. The area embraces about two square miles, has a winter peak load of some 4,200 kva., and a load density of 2,100 kva. per sq. mi. At present this area is fed by circuits from two adjacent areas; it was chosen for the initial economic study because (1) it had relatively definite boundaries and no existing substation and (2) load growth indicated the early necessity of extending the radial system materially or adopting a new system. (See Fig. 2.)

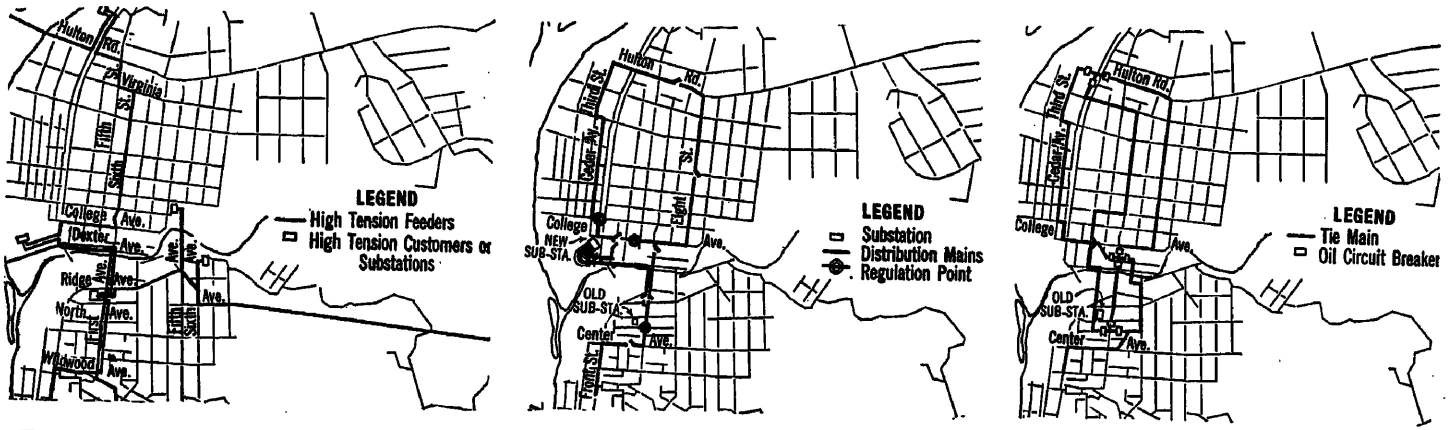
Estimates for extension of the radial system are based upon standard practise in the Pittsburgh district. The necessary substation proposed is a semi-outdoor 22/4-kv. full-automatic type similar to others on the Duquesne Light Company system. Its proposed location was chosen as the result of an economic study of the sites permitted by zoning ordinances, and is reasonably near the expected load center of the area. Initial installation would consist of two 4,000-kva. transformer banks, a 22-kv. tie breaker, three 300-ampere 4-kv. regulated feeders, and related equipment. The building would provide space for an ultimate of two 6,000-kva. transformer banks and five feeders.

The primary network includes exactly the same area and supply from the existing transmission feeders. Transformer and switching units contemplated are the submergible type planned for installation in street vaults. The transformers are 1,500-kva. 22/4-kv. three-phase units with four 2.5 per cent taps below 22-kv. and two similar taps above, and with a three-position disconnecting and grounding switch on the 22-kv. side. The transformer oil circuit breaker is integral with the transformer and comprises a 7.5-kv. 600-ampere unit rated at 14,000 amperes rupturing capacity at 4 kv., 2-OCO. The tie main breakers are similar and they will be arranged to reclose once on a fault, the breakers at each end of a faulty section closing at different times to provide the equivalent of two reclosings. Lead-covered cable is figured in for all 4-kv. work in the vaults and also duct connections between existing manholes and the proposed transformer vaults. Cables are planned to run in pipe from the vaults to the several poles at the related intersection, terminating there in disconnecting potheads.

Both the primary network and the radial plans provide for an operating capacity of 7,500 kva. Primary feeder and duct costs are common to both plans; hence were omitted from the comparison. Relative costs of the two plans as outlined are given in Table II where it may be noted that extension of the radial system will cost 78 per cent more than a change over to the primary network plan. The inherently better voltage regulation of the network is expected to obviate the necessity for regulators.

COMPARATIVE COST ESTIMATE FOR AREA OF 425 KVA. PER SQ. MI.

The Verona-Oakmont area was the second to be studied to determine the relative economies of the radial



Transmission feeders available in Verona-Oakmont area

Radial primary system which ordinarily would be used to supply the area

Primary network mains showing three transformer installations

Fig. 3. Radial versus network system for an area having a load density of 425 kva. per sq. mi.

versus the primary network system. In spite of the fact that the area embraces a total of 4.7 sq. mi. with a total load of only 2,000 kva., or a load density of some 425 kva. per sq. mi., the economies figured out so predominantly in favor of the network that the proposed substation was abandoned and the area converted to a 4-kv. primary network. The network construction is rapidly nearing completion. Also the area in question is of a residential character, with a light commercial load now served at 2.3 kv.

TABLE II—COST COMPARISONS FOR AREA OF 2,100 KVA. PER SQ. MI.

	Radial	Network
Initial Step		
Load	4,200 kva.	4,200 kva.
Transformer capacity installed	8,000 kva.	9,000 kva.
Transformer capacity with spare capacity out of service	5,000 kva.	7,500 kva.
	Costs in per cent	
Real estate	18.0	0.0
Substations	21.0	26.7
Electrical equipment	67.0	56.0
Transmission	1.2	1.5
Distribution	18.4	3.4
Ducts	4.7	10.8
Changes in 4-kv. feeders and mains	0.0	1.1
Total initial step	130	100
Second Step		
Load	7,500 kva.	7,500 kva.
Transformer capacity installed	12,000 kva.	9,000 kva.
Transformer capacity with spare capacity out of service	7,500 kva.	7,500 kva.
	Costs in per cent	
Substation increase	28.0	0.0
Distribution increase	20.5	0.0
Total second step	178	100

Note: Radial system (initial step) will have two 4,000-kva., three-phase, transformers. With one out of service, the other will carry 25 per cent overload through peak or 5,000 kva., which is satisfactory for initial step and allowing for growth.

Network will have six 1,500-kva., three-phase banks and when one transmission line goes out, two 1,500 kva., banks go out also, leaving 6,000 kva. in service which, with 25 per cent overload capacity, gives 7,500 kva. capacity to carry 4,200 kva. initial load.

In the comparative studies of the Verona-Oakmont area a new substation having two 3,000-kva. transformer banks (giving a rated station capacity of 3,750 kva. allowing for 125 per cent load on one bank with the other out) would be the minimum requirement for extension of the radial system. This system also would have required two 4-kv. regulated feeders. (See Fig. 3.)

For the same area the network plan was figured upon three different bases; with:

1. All equipment in underground vaults.
2. Equipment above ground in small buildings.
3. Equipment mounted above ground and outdoors on concrete pads.

Calling the cheapest of these methods (3) 100 per cent, data revealed that the radial scheme represented 35 per cent addition in cost. The underground vault network plan (1) and the small-building plan (2) figures respectively 18 and 7 per cent more costly than plan (3). Comparative data are given in Table III.

TABLE III—COST COMPARISONS FOR AREA OF 425 KVA. PER SQ. MI.

	Radial	Network		
		U. G. Vault	Bldg. Type	Outdoor
Load	2,000 kva.	2,000 kva.	2,000 kva.	2,000 kva.
Proposed inst. capacity	6,000 kva.	4,500 kva.	4,500 kva.	4,500 kva.
Operating capacity*	3,750 kva.	3,750 kva.	3,750 kva.	3,750 kva.
	Costs in per cent			
Real estate	17.0	0.0	2.8	2.8
Substation bldg. or vault	4.2	24.5	13.0	5.8
Equipment	95.0	71.0	66.3	66.3
Transmission	2.5	3.3	4.4	4.4
Distribution	1.6	13.2	13.2	13.2
Duct connections	14.5	5.7	7.5	7.5
Total†	135.	118.	107.	100.

*Based on 125 per cent load on transformers for five hours in case of feeder or transformer failure.

†Note: Cost of regulators included in above estimates.

In pursuing the construction of the Verona-Oakmont primary network it was decided to use one each of the three kinds of installations just mentioned, in order to secure practical operating data. This worked out well because only three transformer points are required for the initial network. As to the future, it is contemplated that underground vaults may be used as required in congested areas where above-ground installations are out of the question because of proper costs or zoning ordinances. Small buildings may be used in less congested and medium-grade residential areas while in lower-grade areas the outdoor equipment on concrete pads and surrounded by a fence may be used to advantage.

In the area in question the vault will require submergible equipment. General details are revealed in the sketch, Fig. 4.

Relay Protection

Network relays similar to those used on low-voltage a-c. networks and providing similar protection are being used on the transformer breakers. Another relay recloses the breaker automatically upon resumption of supply on the feeder. Further protection in the form of a contact-making thermometer is being considered as a guard against protracted overloads. Bus differential protection at each transformer installation will operate to lock all breakers open in case of a fault on the bus at the intersection.

Tie-main protection has been the subject of extended investigation as a result of which overload relays with inverse-time characteristics greater than normally employed have been chosen for the service. With a 400/5-ampere current transformer and a 4-ampere relay tap, the relay will operate in 9 sec. at 480 amperes, and inaccurately on a current as low as 320 amperes. In the plan adopted only the two breakers connected to the faulty line will operate. However, if corner transformers are installed from which tie mains run in only two directions, proper selectivity is impossible with that particular transformer out of service. In general it may prove advisable not to use this design, but rather to run a third tie main to an adjacent intersection.

Watertight hoods on (possible) regulators and watertight cubicles for breakers and all associated equipment also may be noted

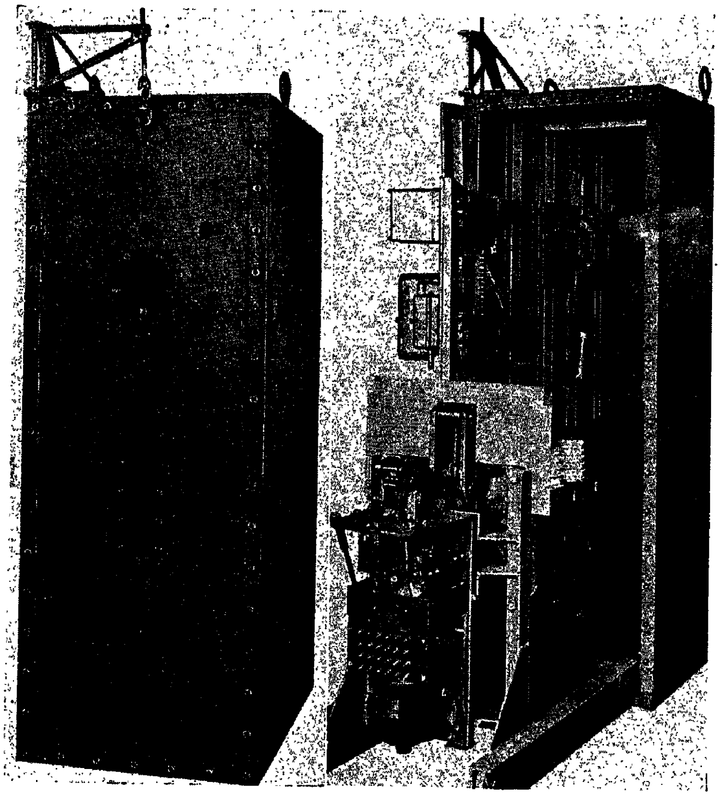

Fig. 6. Submersible cubicle for oil circuit breaker and associated equipment including relays

made of the network layout for three-phase and phase-to-ground faults at all locations along the tie mains, with all transmission feeders in service, and with each one out. Fig. 5 presents a typical analysis. Results in all cases are sufficiently conducive to warrant the expectation that no trouble will be experienced in relaying the Verona-Oakmont primary network, particularly if two-way-feed transformer installations can be eliminated.

CONCLUSIONS

On the basis of studies made, the primary network may be said to offer the following advantages over the usual radial system:

1. Material reduction in investment.
Even under the adverse conditions of load densities as low as 425 kva. per sq. mi., the cost runs as much as 35 per cent higher for the radial system.

2. Greater copper economy.
Reduced copper sizes are possible on the mains because of the smaller currents and shorter distances of feed, the results of the network principle.

3. Reduced duty on oil circuit breakers.
Short-circuit studies of the two areas studied and of theoretical systems indicate that the oil circuit breakers can be materially smaller than for the corresponding radial system.

4. Better regulation.
Any radial system inherently has considerable voltage variation which regulators cannot compensate. It is believed from a theoretical voltage analysis made that a very uniform voltage will be obtained on the network.

5. Small and standardized transformer units.
Transformer units (transformers, switches, regulators, if used, and auxiliary equipment), can be manufactured in units, stocked if necessary, and installed when required.

6. Capacity may be installed in small increments.
The radial system requires a substation and distribution system to be built well in advance of the load growth; long-range estimates are necessary for load growth both in direction and magnitude. In the primary network transformer units are installed where and when needed. Long-range predictions are unnecessary.

7. Investment for load growth in small increments.
The investment is not made in large steps far in advance of the load growth.

8. Reduced system losses.
One item of saving for example, is the complete elimination of feeder losses; there are no feeders.

9. Reduced area of outage.
With the designs considered each tie main will have a capacity of 600 or 700 kva.; the radial circuit has a capacity of 2,100 kva. A failure in the network therefore involves less than one-third the load of the radial system.

10. No 22-kv. breakers.
High-voltage cables run directly to the network transformers.

Vacuum Tubes and Their Applications

The extensive use of the high-vacuum tube in radio and communication work has resulted from certain remarkable characteristics of these tubes; the "thyratron" has been shown to possess certain other characteristics which mark it as being equally well suited to industrial uses.

By
W. C. WHITE
Member A. I. E. E.
General Electric Co.,
Schenectady, N. Y.

VACUUM TUBES may be classified according to (1) number of electrodes (a two-electrode tube, being termed a diode, a three-electrode tube a triode, and so on, to include tetrode and pentode); (2) content of the bulb, which may be high vacuum, gas, or vapor; (3) nature of the fundamental electrode, the cathode, which may be thermionic, photoelectric, mercury-pool, or cold.

For convenience, practically any form of the many types of vacuum tubes can be classified by a combination of these three properties. For instance one sold under the trade name of "tungar" is a gas-content, hot-cathode diode. Screen-grid tubes used so much in modern radio are hot-cathode, high-vacuum tetrodes. The small tubes which are sold under the trade name of "thyratron" are hot-cathode, mercury-vapor triodes.

HIGH-VACUUM TUBES

Fundamentally, the amount of current that can be carried through the vacuum in a hot-cathode, high-vacuum tube is dependent upon the electron emission and space charge effect. The electron emission is known to depend upon many contributing factors while the space-charge factor is controlled by simply introducing a grid into the tube with the proper voltage applied.

In a high-vacuum tube are embodied four features that singly or in combination make for a unique electrical device:

1. Independence of frequency.

The speed of electrons is such that they will respond to frequencies of the order of several million cycles per second, so that for most purposes the tube has no limitations in this respect.

2. Continuous control.

The electrons each carry such a small charge and are in such rapid motion that the current through the tube can follow accurately a very complicated wave form, as distinguished from the step-by-step action which occurs in most other electrical apparatus. This feature has made the high-vacuum tube useful in long distance telephony and radio broadcasting.

3. Voltage control.

Relatively large amounts of current through the tube can be controlled by the grid voltage without furnishing any current to the grid. For example, the electricity generated by rubbing a fountain pen with a piece of cloth, when applied to the grid is sufficient to control relatively large amounts of power. This feature provides for the high amplification common to this type of tube.

4. Rectification.

Current passes through the tube only when the cold electrode is positive with respect to the hot electrode.

From the point of view of these four factors, it may readily be seen why the high-vacuum tube is of such importance in radio. For industrial application, however, the high-vacuum tube has certain serious limitations, these being due mainly to high power loss within the tube. Part of this loss is represented by the power required to heat the cathode to the point at which electron emission will take place; this ranges from about 10 to 150 watts per ampere of current passed through the tube. Another limitation arises from the fact that from several hundred to about one thousand volts per ampere is required to force the current across the vacuum within the tube.

From these facts it will be seen that currents of more than a few amperes cannot be handled economically by means of this type of tube. Therefore, it is apparent that in the industrial field the most promising applications of the high-vacuum tube is in various control operations where the determining factor is the unique characteristics of the tube rather than its output.

THE THYRATRON

Next discussing the thyratron tube, its striking characteristics are the greatly decreased amount of power required to heat the cathode, and a marked reduction in the large voltage drop characteristic of the high-vacuum tube. This is brought about by the introduction of a slight amount of mercury gas or vapor into the bulb, the positively-charged vapor or gas molecules mingling with the electrons and neutralizing the space-charge. This neutralization of the space-charge makes possible a very different design of hot cathode; instead of utilizing what might be termed an open-type cathode permitting the electrons to leave the hot surface easily there may be used an enclosed-type cathode with just a few holes through which the stream of neutralized and negative ions may pass. This means that the heat may be kept within and conserved, whereas the electrons and positive ions may be allowed to travel to the anode. This is accomplished by surrounding the hot cathode with heat insulation and heat reflectors with only relatively small holes for the passage of the current. The resultant power loss is only about one watt per ampere of current through the tube contrasted with from 10 to 150 watts per ampere in the high-vacuum tube.

Also, neutralization of the space-charge eliminates the high voltage necessary to pass the current through the space; and instead of a large voltage increasing with the amount of current to be carried there is a constant-voltage drop of from 10 to 20 volts.

As a result a thyratron tube built to about the same physical size as the commonly-known UX-250 high-vacuum tube, and costing about the same amount to manufacture, will handle about 50 times as much current as the latter. It is apparent therefore, that the gaseous type of electrostatically-controlled tube is much better suited to the handling of relatively high currents common in the broad field of electrical engineering than is the controlled high-vacuum type.

Nevertheless, a thyratron tube has certain limitations; as stated, the high-vacuum type can handle currents up to a frequency of one million cycles per second, whereas the thyratron in its present form is limited to a few thousand cycles per second. Also the thyratron cannot control direct current in the same simple way as the high-vacuum tube; that is, it lacks the feature of "continuous control." These, however, are not serious drawbacks for most industrial uses and it appears that even as the characteristics of the high-vacuum tube fitted it remarkably into the radio communication field, so the thyratron tube may be considered equally well adapted for use in the industrial engineering field.

From a paper "Vacuum Tubes, Their Industrial Applications," presented informally at a meeting of the Schenectady Section of the A. I. E. E., Jan. 16, 1931. Reprints not available.

What are Effects of Electric Shock?

By
W. B. KOUWENHOVEN
Member A. I. E. E.
Johns Hopkins University, Baltimore, Maryland

O. R. LANGWORTHY
Non-member
Johns Hopkins University, Baltimore, Maryland

Are brain cells injured when currents do not pass through th head? What influence upon life continuity does the current path through the body have? In an effort to approach an answer to these and related questions a second set of experim ntal data is given herewith.

IT IS WELL RECOGNIZED that the point of bodily contact is a factor of great importance in cases of injury resulting from exposure to energized electric circuits. Physical danger to vital body tissues is the source of greatest danger to life continuity in cases of electric shock, and the location of the point of contact determines largely the pathway of current flow. Once inside the body the current spreads out in a more or less fusiform shape, but it is difficult to believe that the current density can be high in organs distant from the most direct path between points of contact. For example, if a man makes contact with an electric circuit through one arm and one leg, it is scarcely possible that any appreciable current will pass through his brain.

REVIEW

Before proceeding further with the present discussion it may be well to recapitulate briefly because earlier experiments reported upon[1] (for numbered references, see bibliography) brought to light certain facts which apply to the present series.

In the earlier tests electrodes were applied only to the head and tail of the animal subjects. Rats were used as the experimental animal and both continuous- and alternating-voltage shocks were administered at 110, 220, 500, and 1,000 volts. At each voltage the duration of contact at first was short and subsequently increased until it was impossible to resuscitate the subject by means of artificial respiration. These tests revealed that:

1. A 1,000-volt continuous current was more dangerous to rats than an alternating current of the same effective voltage.
2. A large rat survived a greater shock than a small rat.
3. Both sexes were equally susceptible to electric shock.
4. Paralysis of the hind legs resulting from hemorrhages in the spinal cord characterized many of the a-c. experiments.

With the electrodes on head and tail the brain was directly in the current path and the studies showed that the brain appeared to be injured readily by the passage of an electric current through it. Subsequent to the death of the rats evidences of nerve-cell damage and of both macroscopic and microscopic hemorrhage in the brain were found in many instances.[2]

In legal electrocution one electrode is placed on the skull, but industrial accidents rarely involve head contact; the common path is from hands to feet.[3]

RECENT EXPERIMENTS

The recent series of experiments was undertaken to study the influence of the current path upon the effects produced by an electric shock. Are injuries to brain cells produced when the current does not pass through the head? Rats again were chosen as animals for study because of accurate knowledge of their behavior and because a rat seldom if ever dies of damage to heart after an electric injury, but rather from respiratory failure. Using a 1,000-volt circuit, 102 rats were shocked, half with a-c. and half with d-c., each for a period of two seconds. Electrode positions were varied and a few tests were made with the electrodes on the head and tail of the animals to check the results of the prior series.

Preparatory to the shock the rats were given ether until they were quiet, then the points of contact were moistened thoroughly with saline solution and the electrodes (voltmeter clips filed smooth) attached. When connection was made to the head a special electrode was employed which made contact only on the upper surface of the skull and did not interfere with breathing. After the electrodes were in place the shock was applied. In each case the circuit was held closed for exactly two seconds and the current flowing through the animal was recorded.

Immediately following the shock, the animal was removed from the circuit and if there was no evidence of breathing, artificial respiration was applied. This consisted of the application of digital pressure upon the chest, reproducing so far as possible the Schaefer prone-pressure method. Also the tongue was pulled out, the vagus nerves in the neck were stimulated by stroking with the fingers, and efforts were made to keep the respiratory tract free from mucus.

Following the a-c. injuries the chest of the animal was fully expanded, a seemingly important aid to the resumption of spontaneous breathing or to adequate artificial respiration. However, after contact with the d-c. circuit the chest was collapsed and it was difficult to get air into the lungs. The a-c. shocks produced a strong contraction of musculature of the body and this in the cases of males was accompanied almost invariably by an emission. Clonic movements of the muscles of the leg were observed in many of the a-c. injuries, probably produced by irritation of the nerve cells due to asphyxiation. Bleeding of the conjunctiva also occurred in many cases.

ELECTRODES ON HEAD AND TAIL

Six rats in the present series and ten in the prior series were subjected to a two-second contact with a 1,000-volt a-c. circuit with electrodes affixed to head and tail. Artificial respiration was required and applied in 88 per cent of the cases, and five or 31 per cent recovered. The others died or were paralyzed by the shock. Three of the five that recovered were normal. After breathing was established it was rapid, shallow, and somewhat irregular for several hours following the injury, later becoming normal.

Only one of the six rats in the present series was paralyzed as against five of the ten in the prior series; in fact in the present group paralysis was less common and fewer hemorhages in the spinal cord were found than in the tests of a year ago although no explanation for the discrepancy can be given. A brief analysis of tabulated results shows that:

1. Of the five subjects to recover, the average weight was 217 grams and the average body current 0.848 ampere.
2. Of the six paralyzed subjects, the average weight was 242 grams and the average body current 0.800 ampere.
3. Of the five subjects which died, the average weight was 161 grams and the average body current 0.844 ampere.

In the tests previously published no rat survived a contact of one second or more with a d-c. circuit of 1,000 volts. Therefore, in this series only two animals were given a two-second shock at this voltage and neither of them survived although their hearts beat strongly for several minutes following the contact. Autopsy showed only few abnormalties, but microscopic examination of the brains of the rats of the prior series revealed that the current had caused nerve-cell injuries incompatible with life.

Observations in the present group check with those of the prior experiments where the electrodes were applied to the head and tail of the animal. It is clearly evident that contact with a 1,000-volt d-c. circuit is much more deadly to a rat than contact with an a-c. circuit of the same effective voltage. In this series, artificial respiration was applied to all of the animals tested with continuous current, and 100 per cent of them died. In the a-c. tests, however, artificial respiration was needed in only 88 per cent of the cases; 31 per cent of the animals died, 38 per cent were paralyzed, and 31 per cent recovered from the injury.

ELECTRODES ON RIGHT FORE LEG AND TAIL

Twelve rats were given a two-second 1,000-volt a-c. shock with electrodes on the right fore leg and tail. Five of these rats breathed as soon as the circuit was opened; in the other seven cases artificial respiration was required. Death occurred either immediately or within a few minutes in 42 per cent of the cases; three rats were paralyzed, one of which died four hours after the injury, another, nine hours, and the third survived until killed preparatory to autopsy.

This group was of particular interest in emphasizing the fact that an animal was not necessarily on the road to recovery when breathing was first started. This phenomena is mentioned often in records of human electric shock. Breathing was started in three of the rats only to cease after a few minutes and a second application of artificial respiration saved only one. Several of the rats in this group were hyper-irritable to all sensory stimuli for some minutes following the injury. Bleeding from the eyes was a common occurrence. The paralyzed rat that survived had a hemorrhage in the spinal cord and there was no chance of its permanent recovery.

With the alternating current flowing through the animals from right fore leg to tail 35 per cent of them recovered, 42 per cent died, and 25 per cent were paralyzed. The injury was slightly less severe than when the brain formed part of the current path as in the previous series.

Another twelve rats were tested on a continuous-current circuit with electrodes also on the right fore leg and tail. In this test the brain did not lie directly in the path of the current and the results were vastly different from those where one contact was made with the top of the skull. Here six of the rats breathed spontaneously when the circuit was opened, whereas none were saved in the first series even after long applications of artificial respiration. There was only one rat in this group of twelve that did not attempt to breath after the injury.

Artificial respiration was applied in 50 per cent of the d-c. cases; 42 per cent recovered; 25 per cent died, and 33 per cent were paralyzed; but these figures do not tell the whole story. Burns resulting from contact with direct-current were much more severe than those observed with alternating current. Because of these burns it was not possible to keep any of the surviving animals alive for a period longer than three days following the d-c. shock. However, any rat that survived an a-c. shock without paralysis appeared quite normal 24 hours later; they ate, drank, and were active. It is of interest also to note that in this d-c. group there were two cases where breathing was started only to stop again. In both of these instances a second application of artificial respiration was unsuccessful. Further brief analysis of tabulated results of this group of tests involving 24 rats shows that:

1. Of the four subjects which recovered from a-c. shock the average weight was 171 grams and the average body current 0.767 ampere; of the five recoveries from d-c. shock, 108 grams and 0.754 ampere.

2. Of the three subjects paralyzed by a-c. shock the average weight was 179 grams and the average body current 0.743 ampere; of the four paralyzed from d-c. shock, 130 grams and 0.887 ampere.

3. Of the five subjects dying from a-c. shock the average weight was 174 gram and the average body current 0.718 ampere; of the three succumbing to d-c. shock, 103 grams and 0.800 ampere.

From these results it is clearly evident that in cases where the continuous-current path does not include the brain there is at least a fifty-fifty chance of resuscitating the animal.

ELECTRODES ON LEFT FORE LEG AND TAIL

Twenty-four rats were tested with the electrodes on the left fore leg and the tail, half with alternating and half with continuous current. Under alternating current, artificial respiration was applied in 75 per cent of the experiments; 58 per cent recovered, 17 per cent were paralyzed, and 25 per cent died. With direct-current, artificial respiration was used in only 58 per cent of the cases; 42 per cent recovered, 33 per cent were paralyzed, and 25 per cent died.

The results of this series also emphasized the fact that breathing will not necessarily continue after having been established either spontaneously or by artificial respiration. Reactions and behavior of the rats in this group were closely identical with those where the current path was from the right fore leg to the tail. It was not, however, quite so dangerous to life. The d-c. results here also confirm the importance of eliminating the brain from the current path if any hope of recovery for the animal is to be entertained.

ELECTRODES ON BOTH FORE LEGS

Eight rats were tested with electrodes on both fore legs, thus involving the heart and lungs directly in the path of the current flow; four were shocked with alternating, and four with continuous current; their average weight was 144 grams and the average body current was 1.24 amperes.

Although artificial respiration was tried in every case, no animal survived, a fact not strange when one considers the current that flowed for two seconds. The chest was warm to the touch when the circuit was opened. In all but one case, however, the heart continued to beat following the shock. It is remarkable that there was any heart beat at all after so severe an injury, and that two of the rats attempted to breathe following the a-c. contact and two following the d-c. contact. There is no possibility of survival with this current path.

ELECTRODES ON BOTH HIND LEGS

Fourteen rats were tested at 1,000 volts with electrodes attached to both hind legs, seven on an a-c. circuit and seven on a d-c. circuit. Their average weight was 127 grams and the average current that flowed for two seconds was 1.17 amperes. Only one rat died as a result of the a-c. contact, and two from the d-c. contact, when the circuit path involved principally the caudal region of the body. The rat that died after the a-c. contact had started breathing spontaneously as soon as the circuit was opened. He was considered as recovered and had been placed back in the cage; ten minutes later he was found dead.

Artificial respiration was not applied to any of the seven rats that were injured with alternating current. All breathed spontaneously and 86 per cent recovered completely. They were all active and lively within a few minutes following the shock. One, or 14 per cent, died, and it is believed that his life could have been saved had artificial respiration been applied at the proper time. Following the d-c. shock, five of the animals breathed at once. Artificial respiration was applied in but two cases, (29 per cent) and these animals died after a few attempts at breathing. The other five (71 per cent) recovered and in a few minutes became very active.

These tests demonstrate clearly the fact that when none of the vital organs lie directly in the path of body current the electrical injury usually is small.

ELECTRODES ON ONE FORE LEG AND ONE HIND LEG

Effects produced by the flow of current from the right fore leg to the left hind leg were studied in eight rats, from the left fore leg to the left hind leg in eight other rats, and in a third group of eight the electrodes were on the left fore leg and the right hind leg. Half of these were subjected to an a-c. circuit and the remainder to a d-c. circuit.

Not a single rat was permanently saved after contact with the d-c. circuit; one was resuscitated but only to die two and a half hours later. In several cases no heart action could be detected and at most, many of the animals gave only a few gasps. There was greater success in saving those that had been injured with alternating current, where in five cases breathing was established by a long application of artificial respiration. One of this five was paralyzed, but all including the paralyzed one became quite active soon after the shock.

Results for the 24 cases where the current path was from fore to hind leg, may be summarized as follows:

1. Artificial respiration was applied in every instance, both for the a-c. and d-c. contacts.

2. With alternating current 33 per cent of the animals recovered, eight per cent were paralyzed, and 59 per cent died.

3. With continuous current 100 per cent of the animals died.

4. Of the four subjects which recovered, the average weight was 116 grams and the average body current 0.910 ampere.

5. The rat that was paralyzed weighed 143 grams and the current that flowed was 1.060 amperes.

6. Of the nineteen subjects which succumbed, the average weight was 132 grams and the average body current 1.211 amperes.

Normally one would expect that there would be little if any difference between the effects produced by a current flowing from either fore leg to tail or by one flowing from either fore leg to either hind leg; yet in the group where the current path was from fore leg to tail, 44 per cent of the rats recovered; in the second group where one electrode was attached to a hind leg instead of the tail, only 16 per cent were saved.

Wherein, then, lies the deadliness of this current path from fore leg to hind leg? The authors believe that the high death rate found here is caused by the low-resistance path that the animal offers to a current flow when its tail is eliminated from the circuit. The average resistance of the current paths from fore legs to hind legs for the 24 rats was less than 70 per cent of that found for the 48 rats where the current paths were from either fore leg to tail. The higher resulting current is believed to be responsible for the deaths of the animals. A second argument supporting this conclusion is the almost complete absence of serious injury to the rats when the current passed from one hind leg to the other, even though the current values were high.

DISCUSSION AND CONCLUSIONS

These experiments confirm Urquhart's[4] conclusion that when an electric current passes through the brain a temporary physiological block is produced in the respiratory center and that spontaneous breathing ceases for a time. He stated that if no serious injury to the heart occurs, adequate artificial respiration may give time for the center in the medulla to recover and for normal breathing to begin. Maclachlan[3] reports in his field notes a case of recovery from shock following eight hours of continuous application of the Schaefer prone-pressure method, which also confirms Urquhart's findings. Urquhart[5], in a second series of experiments, demonstrated that a temporary block could be produced in the spinal cord or in a nerve trunk by the passage of an electric current.

Langworthy[2] found by his microscopic examination of sections of the brains of the rats injured by high-voltage electric currents that in many cases the damage to the cells was incompatible with life. Microscopic study of the central nervous systems of all of the rats in this present series will be made.

Results obtained clearly demonstrate the presence in many of the rats of a temporary respiratory block, the location of which, whether in the brain stem or in the vagus nerves, depends upon the current path. Resuscitation is possible provided the damage done does not require a recovery time too long to permit life to be supported in the interval.

Effects produced by the various current paths through the animals are summed up in Table I. From that table and from the results presented, the following conclusions may be drawn:

1. A 1,000-volt continuous-current circuit is more dangerous to rats than an alternating circuit of the same effective voltage, irrespective of the current path.
2. The chances of recovery are best when the brain does not lie directly in the pathway of the current.
3. The injury produced by the current path from the left fore leg to the tail is less severe than that caused by the same current flowing from right fore leg to tail.
4. When the main pathway of the current did not include the brain, spinal cord, or nerves required for respiration, most of the animals breathed at once and were active a few minutes after the injury.
5. The presence of a respiratory block has been demonstrated, and the fact that when natural breathing is first established the animal is not necessarily on the road to complete recovery.
6. The respiratory block is less severe, if not absent, when the current traverses the posterior portion of the body.
7. Burning of the tissues with continuous current is much more severe than occurs for the same effective alternating current.

TABLE I—SUMMARY OF RESULTS OBTAINED IN EXPERIMENTS
Submitting 161 Rats to Contact with 1,000-Volt Circuits for Two-Second Shock Periods

Current	Position of electrodes		Number shocked	Per cent requiring artificial respiration	Per cent immediate recovery	Per cent paralyzed	Per cent immediate death
Alternating	Head	Tail	16	88	31	38	31
Continuous			3	100	0	0	100
Alternating	Right fore leg	Tail	12	58	33	25	42
Continuous			12	50	42	33	25
Alternating	Left fore leg	Tail	12	75	58	17	25
Continuous			12	58	42	33	25
Alternating	Either fore leg	Tail	24	67	46	21	33
Continuous			24	54	42	33	25
Alternating	Right fore leg	Left fore leg	4	100	0	0	100
Continuous			4	100	0	0	100
Alternating	Right hind leg	Left hind leg	7	0	86	0	14
Continuous			7	29	71	0	29
Alternating	Either fore leg	Either hind leg	12	100	33	8	59
Continuous			12	100	0	0	100

Electric Power in the Steel Industry

A brief outline of some of the revolutions in production methods brought about by electrification on a large scale.

By
G. E. STOLTZ
Member A. I. E. E.

Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

SINCE the World War practically every industry has been subject to a declining market price of its commodity. The very definite problem before industry during this post-war period has been to modify production methods and processes in a manner which will permit the manufacture of commodities at a constantly declining cost.

Perhaps in no industry has there been greater progress in recent years than in the steel industry and some of the major advances that are attributable to the application of electricity, not only to auxiliary drives and annealing processes but also to the replacement of the large steam engines for main roll drive with motors, far exceed in performance and output anything obtainable by steam. Perhaps even more vital than the application of motors to main rolls has been the installation of delicate and accurate control devices which has brought about a complete change in the rolling of steel.

Up to 1921 the steel industry had been accepting electrification but not in the wholehearted manner as it now does. As to main rolling drive, there was considerable argument between the steam advocates and those who were in favor of electric drive; but when the steel industry was definitely confronted with a steady decline in the price of steel products the curtain was drawn abruptly on further debate and many large engines were replaced by electric drives. At that time an electrified plant enjoyed an advantage of $2.50 per ton of product over a steam-driven plant; at present this difference is even greater.

One of the first products to feel the far reaching effects of electrification was strip formerly rolled in mills where the metal was passed back and forth by hand from one stand to another. The drawback in this type of mill was not only that it required a great amount of hard labor but that the thin metal traveling along the cold floor would lose its temperature rapidly. The tandem motor-driven mill arrangement not only reduced the amount of power required to roll the steel but enabled the same slab to be finished to a thinner gage.

So long as steam engines were used this newer type of tandem mill of course was impossible because it is necessary to have, for the driving of each stand, individual units which can be adjusted in speed to accommodate different drafts in individual stands and maintain a pre-set speed whether the load be light or heavy.

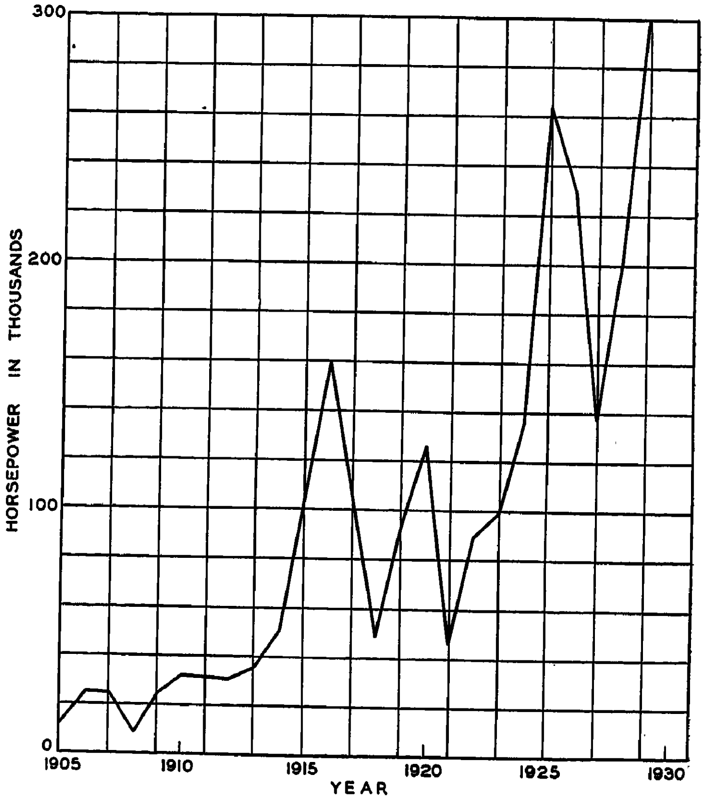

Fig. 1. Installed horsepower on main-roll mill drives is increasing rapidly

Strip usually covers a range from 3 to 20 inches in width while sheet varies in width from 30 to 60 inches. Since the continuous type of individual motor-driven mills proved so successful in strip mills it is only natural that present day production of heavy sheets is being drastically changed. The transition has not reached

---

From "The Use of Electricity in the Steel Industry," presented at the Western Metals Congress, San Francisco, Feb. 16-21, 1931.

that same conclusive state as it has in strip mills and at the present time only the heavier sheets are being rolled on this type of mill. It is possible however that in the near future continuous rolling of sheet will be almost as complete as the continuous production of strip.

From sheet to plate is the next logical step; consequently the first installation of a continuous plate mill is being made now. In other words the use of the tandem-mill motor specially designed for flat speed regulation has gone from strip to sheet mills and now is invading the plate-mill field. In general, the old type of mill was able to produce from 10,000 to 15,000 tons per month.

Recently with the development of structural shapes has come a new type of wide-flange mill where motor drive has been utilized. In the rolling of these larger and relatively more complicated shapes only the advent of sensitive, sturdy, and accurate automatic electrical control devices has made the wide-flange mill an operating success. In one mill typical of this a 7,000-hp. motor drives the main rolls (used on the web and inside flanges of a beam) and also two vertical rolls which reduce the outsides of the flanges. Adjacent in the line of production is a set of auxiliary horizontal rolls which reduce the edges of the flanges. These auxiliary rolls are driven by a 2,000-hp. motor. It is essential that these two motors remain in synchronism regardless of the relative load on either of them. Also, with the material passing back and forth between these three sets of rolls and with the different drafts to be taken on the rolls, various speed relations between the three sets of rolls must be pre-set and rigidly maintained for any given pass. This represented one of the difficult problems in the design of the electrical equipment for this mill. It not only required a careful designing of the control but of the motor as well.

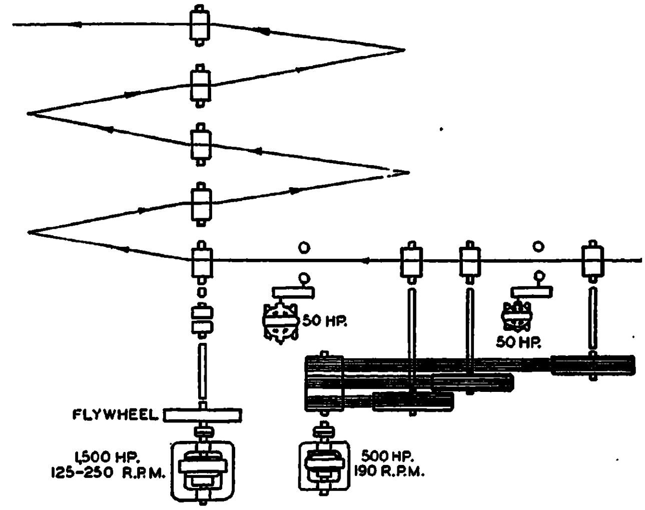

Fig. 2. Layout of typical older type of 14-in. strip mill showing hand transfer between finishing stands. Compare with Fig. 3

The other problem was to establish a proper setting for the three sets of rolls as the metal was being reduced from a beam blank to a finished beam. It may be imagined that if heavy drafts were taken in the vertical rolls during the early passes, while most of the work to be done by the main horizontal rolls was delayed to the last few finishing passes, there would be considerable distortion and unnecessary strain set up in the metal. With three sets of rolls to be adjusted after each pass it was inconceivable that two men would reproduce properly the drafts as each piece of metal came through the mill, a matter of importance in securing uniform elongation of the metal throughout its entire section; further, unless drafts could be predetermined it would be impossible to pre-set the speed of the 2,000-hp. motor. For this reason arrangements were made to operate the screwdown on the three sets of rolls automatically for each individual pass and at the same time adjust the field of the 2,000-hp. motor for its correct speed. This automatic setting of the rolls for each individual pass was the second distinct contribution made to the phenomenal success of this type of mill by electrification.

FUTURE PROSPECTS

There are many other instances where the steel industry has utilized electrification to maintain a prosperous condition regardless of the decline in the price of steel. Probably one of the most spectacular changes from a labor point of view is in the production of wrought iron. At the present time one company is incorporating a method of manufacturing wrought iron by merely pouring the molten iron from one ladle into another containing molten slag. In three minutes a three-ton ingot is produced by a few men, whereas by the old method it took twenty men two hours. The old method of puddling might be termed a back-breaking job meant for young men only; today the seasoned man of fifty with steady habits is better adapted to manipulate the machinery required for this new process.

There is no question but that still further changes of great consequence to steel production will be obtained through the use of electricity. As yet there is little appreciation of the full use to which electricity may be placed, but these possibilities will be unfolded in the future just as they have been in the past.

A Neutralized Welding Generator

By reducing the magnetic energy stored in the generator field, transient currents in d-c. welding machines can largely be eliminated. Providing such generators with neutralizing windings reduces this energy to a minimum.

By
F. CREEDY
Member A. I. E. E.

Lehigh University

ARC-WELDING generators of the d-c. type in order to be satisfactory not only must operate at constant current over a wide range of voltages, but must also be free from heavy transients. The operation of such machines can be improved vastly by incorporating in their design a winding to neutralize the effect of armature reaction in the generator, and a high external reactance in series with the arc.

It should be noted at the outset that two different types of welder are possible—the separately-excited type and the shunt type. The former type has a separately-excited coil in its field, its ampere-turns opposed by a coil connected in series with the armature; the shunt type, in addition to this, has a shunt coil on the field.

It is proposed that in the case of a shunt type of welder its shunt coil and separately-excited coil should be combined into one in the manner shown in Fig. 1. If to a shunt coil and a separately-excited coil, each of resistance R, are applied voltages E_1 and E_3 respectively, the currents in each will clearly be E_1/R and E_3/R. If instead of this a single coil is used, still of resistance R, and is submitted to an e. m. f. equal to $E_1 + E_3$, then the current will be $E_1/R + E_3 R$; that is, the ampere-turns will be just the same as in the case of the two separate coils. This construction provides a minor simplification in the design of this particular type of machine. Its chief advantages, however, are that by rendering leakage between the shunt and separately-excited windings impossible (since they are now the same winding), it reduces transient currents and prevents damping of the shunt currents by the separately-excited winding.

In any study of welder design, a careful consideration of transient characteristics is of the utmost importance. Although the steady characteristics of a welder may show a constant current for a wide range of voltage, if transient variations from these conditions are possible, the machine still will be unsatisfactory.

If the current is capable of a sudden jump from one value to a higher one, then any sudden shortening of the arc or contact with the work means that an excessive amount of energy is suddenly concentrated in it, resulting in an explosion with the familiar "spluttering" so annoying to welders. This spluttering is almost entirely the fault of the generator.

It will be clear now that the steady characteristic of the generator (for instance as measured on a resistance load), does not indicate whether it is good or bad for welding purposes. It must have an additional quality which is vaguely called stability; which brings up the question as to how this stability may be calculated and measured?

It is proposed that the stability of all welding apparatus be defined in terms of what may be called the "stability ratio," and that the stability ratio be defined and measured by (1) applying full load to the welder by means of a resistance, as for example, 200 amperes at 30 volts; (2) by arranging a switch so that the resistance may be short-circuited instantly thereby instantly short-circuiting the terminals of the machine through the steadying reactance; and (3) by measuring the maximum current kick produced (600 amperes for example) when the short-circuiting switch is closed. The stability ratio is then the ratio of this maximum kick to the normal full-load current.

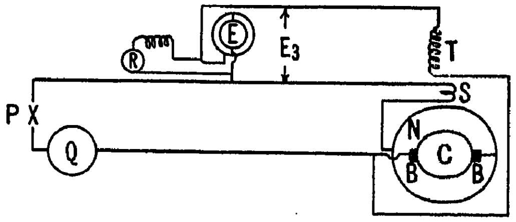

Fig. 1. Schematic diagram for neutralized welder

The shunt and separately-excited fields have been combined in a single winding T. The neutralizing winding is designated at N while Q represents the arc series reactance

In the example given, where the kick is 600 amperes and the full-load current 200 amperes, the stability ratio is 3. Under a small stability ratio the welder will operate steadily.

There is no serious difficulty in measuring this kick by well-known methods with instruments ordinarily found in a test room: First the glass front is removed from an ammeter, preferably one of the moving-coil or dynamometer type whose moving system has a low moment of inertia. By means of a pencil point, or otherwise, the needle is held at approximately the value

---

From "The Neutralized Welder—A Means of Controlling Transients," (No. 31-31), Presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

which the current is expected to have—say 600 amperes. Next, the machine is short-circuited, and if the current is less than the value indicated by the pointer, it will continue to rest against the pencil point and be prevented from moving back to zero. If the current is greater, the needle will momentarily flutter away from it to a greater or less extent. If, however, there is no flutter, the test should be repeated with the needle held opposite a lower reading on the scale, say 500 amperes. If the flutter is vigorous, the needle should be held opposite a higher reading on the scale, for instance 700 amperes—the test being repeated until a point is found where the needle shows only a slight indication of movement. By this means, using only standard d-c. instruments, the instantaneous short-circuit current may be measured with fair accuracy.

It is necessary that the voltage of the generator be able to respond rapidly to changes in arc length while the current remains constant; it would seem therefore that the separately-excited type of generator in which no voltage variation whatever can take place unless there is current variation must be inferior to the shunt type in which voltage and current variation are independent of one another. Up to a few years ago this reasoning was common but since as hitherto designed the shunt type of machine was found to be sluggish—that is, the voltage did not rise sufficiently fast with increasing arc length—it has fallen into disrepute.

After a rather complete mathematical study of welder transients it was concluded that this sluggishness arises from the large amount of magnetic energy stored in the field system of machines of ordinary design. For instance when the voltage increases, the flux of the machine must increase also; and if this requires a large increase in magnetic energy, then a certain amount of time must elapse before that energy can flow in. The proposal outlined in the beginning provides that the magnetic energy stored in the field system be reduced to a minimum. Again if there is leakage between the series and the shunt or separately-excited coils, or to borrow a term from radio practise, they are "loosely coupled," the transient current in the separately-excited coil is not closely conditioned by current changes in the series coil.

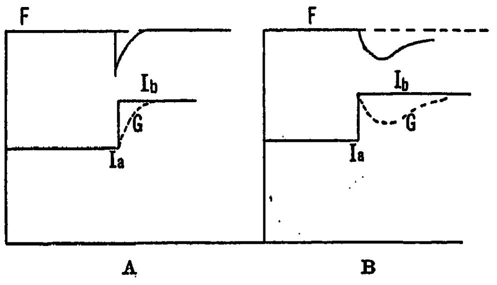

Fig. 2. Current diagrams for a generator with small field leakage (A) and high field leakage (B)

I_a and I_b represent the welding current, F the current in the separately-excited coil, and G the resultant ampere-turns

The foregoing is illustrated in Fig. 2; in the case of small leakage as shown at A, when the welding current rises from I_a to I_b, the increased ampere-turns of the series coil are instantaneously masked by equal and opposite ampere-turns in the separately-excited coil whose current is shown at F; if the energy stored in this circuit is small, these transients die away at an exceedingly rapid rate so that the flux very rapidly takes up its new value. With high leakage as shown at B, the change in the ampere-turns in the series coil immediately influences the flux, since the transient currents in the separately-excited coil have considerable lag. Later the transient current in the separately-excited coil starts causing the flux to return to nearly its original value after which the transient gradually dies away, the net effect being that the flux first falls, then increases, and then gradually falls again—a very undesirable condition. Hence, one may summarize the condition which leads to good transient characteristics in a welder by stating that there should be "close coupling" between the series and shunt or separately-excited coils. It has been shown that under this condition both the magnetic energy and the leakage should be small.

In Fig. 3 are shown oscillograms of welding current for a welder whose field windings are separate and those for a welder arranged as shown in Fig. 1. By comparison of these two curves it is obvious that the initial rise of current which is universal in welders whose transient characteristics have not been carefully studied, is entirely absent in welders designed as previously outlined. It is evident that in the latter case there is no sudden concentration of energy when the electrode touches the work.

Results of a thorough, mathematical study of the problems involved are briefly summarized in the following paragraphs.

In the welding generator, two distinct problems exist:

1. The current must be held constant during rapid changes of conditions. This is solved by the use of reactance.

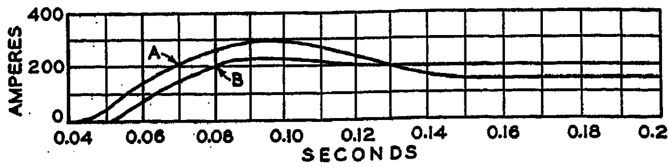

Fig. 3. Current-time relations in a neutralized welder suddenly subjected to full load. (A) Shunt and separately-excited fields independent; (B) single winding used for both

2. The machine must be so designed that the voltage generated may vary rapidly to meet changes of conditions without much change of current.

It is essential to recognize that there are two distinct problems and not one, and that only the second of these requires the use of a special generator. Every change in voltage involves a change in field strength, and in connection with this the following requirements should be noted:

1. Rapid changes require that field variations must take place with only a small inflow or outflow of magnetic energy to the field; or in other words, *the magnetic energy stored in the field shall be as small as possible.* For this purpose the generator should be designed with: (a) low saturation, (which will be secured in any case, owing to the need for a high voltage on open circuit); and (b) the shortest possible air-gap involving semi-closed rotor slots and laminated pole tips.

2. Low magnetic energy means very rapid increment or decrement of flux to meet changed conditions; and also the absence of oscillations where a large external self-inductance is used.

3. Oscillations are due primarily to the fact that the magnetic energy stored in the field is about equal to that in the reactance. This condition should be avoided; the energy stored in the reactance should be much greater than that stored in the field.

4. To store a large amount of energy, the reactance should have many turns, and a fairly long air-gap. (It may be made of cast iron, or cast steel.)

5. It is common practise to use for this purpose the reactance of the armature circuit due to the cross-flux. This is bad practise because: (a) The necessity for a short air-gap has just been pointed out in the interests of low stored field energy. (b) If there are many armature turns with a short air-gap, the cross-flux will produce high saturation, tending to increase the stored field energy: (c) If the pole arc is wide this cross-flux will create sparking. (d) If we reduce the pole arc to avoid this, we reduce the reactance formed by the cross-flux and increase the reluctance of the field. (e) A concentrated interpole winding diminishes the effectiveness of the machine as a reactance.

6. Because of this, it is better to use a *neutralizing winding* or distributed interpoles, completely abolishing the cross-flux, and to have the reactance in separate form. The endeavor to combine the conditions for maximum reactance and the opposite conditions for minimum field energy mean that neither set of conditions can be met satisfactorily; only separate pieces of apparatus can satisfy both in the best possible manner.

7. Even with a purely separately-excited machine this is true. If there is a shunt coil in addition, the placing of the reactance external to the tapping points of the shunt circuit has the further advantage of shielding the shunt winding from the rapid oscillations of the arc.

8. Owing to lag caused by the self-induction of the main field, connecting the shunt winding directly across the arc does not enable it to follow rapid variations, although it can follow fairly slow ones. It is therefore better to rely upon the reactance to deal with rapid variations, and shield the shunt winding from them.

9. The lower the field energy and the higher the field resistance, the more rapid are the variations which can be followed.

10. The higher field resistance also tends to check oscillations but more power is required for excitation, and in a machine with a shunt circuit it is desirable that the field resistance be such as will give the constant-current condition. It seems better therefore to rely on other means; namely, low field energy, and high external reactance to avoid oscillations, and *not* connecting the shunt circuit directly across the arc. This last is perhaps a point of secondary importance, and one to which some difference of opinion might be allowed.

11. Leakage self-induction in the shunt or separately-excited circuit prevents rapid response by permitting the shunt current to vary at a different rate from the armature current. Such leakage is the *sole* cause of these variations.

12. If there is no leakage between the series coil and the shunt or separately-excited coil, all currents must vary at exactly the same rate making "sluggishness" impossible.

Welders designed in this way may be built conveniently with slotted stators, although this is not necessary. This construction renders it possible to reduce greatly the cost of a welding set by combining the welding generator itself with an induction motor in the same magnetic structure. It can be accomplished as shown in Fig. 4. The two machines are arranged for different pole numbers, circuits belonging to the welding generator being at the back of the slots while those of the induction motor are at the front. The rotor has an ordinary d-c. winding suitable for the welding generator and fitted with equalizers. Through these equalizers the secondary currents of the induction motor flow, and in this way are prevented from appearing at the commutator at all. An illustration of the complete apparatus as built with vertical shaft is given in Fig. 5.

Line-to-ground voltage in three-phase grounded-neutral electric power systems under fault conditions often may be greater than the line-to-line voltage. This and numerous other important relations are shown by an investigation of the wide range of power-system voltages and currents existing under fault conditions.

SINCE THE INTRODUCTION of the method of symmetrical components as a powerful tool for the solution of electric-circuit problems, it has been used in many system analyses. Utilizing symmetrical components, this article shows by means of curves and tables the full range of fundamental-frequency voltages and currents obtained in a three-phase system under various fault conditions; it discusses also certain phases of application such as grounding and circuit-breaker duty, and points out the not generally appreciated existence of certain abnormal values in typical systems.

In terms of symmetrical components any symmetrical system is defined and described fully by the generator voltages and the positive-, negative-, and zero-sequence impedances. Thus, Fig. 1 shows the equivalent diagrams of a system for three-phase, line-to-line, single-line-to-ground, and double-line-to-ground short circuits. Since the system is symmetrical, identical values of voltage and current are obtained for any one type of short circuit regardless of which particular phases are faulted; details of the analytical work are simplified for any one type of short circuit, however, if the reference phase (phase *a*) is the one which is open when the other two phases are faulted, and vice versa. Fig. 2 shows the sequence network connections from which the components of current and voltage of phase *a* are computed; and from these latter, in turn, the components for phases *b* and *c* are obtained readily. Because of the large number of possible variables it is desirable before drawing up curves illustrating the ranges of voltages and currents to make certain common assumptions and simplifications. For instance, it is assumed that the system is short-circuited from no-load and internal generator voltages equal and in phase; that the system is without shunt capacitance; and that short-circuit currents are limited only by (inductive) reactance except in the ground-current path, where resistance also is considered. For the sake of generality the sequence impedances are expressed as ratios to the positive-sequence reactance, the latter being that which determines the three-phase short-circuit current; currents are expressed as ratios to the three-phase short-circuit current, a convenient reference quantity; voltages, both line-to-ground and line-to-line, are expressed as ratios to their respective *normal* values. Thus for a given system the curves may be used by computing the ratios of sequence impedances.

TABLE I—LIST OF SYMBOLS
(See Illustrations)

a, b, c = the three phases of a three-phase system in which normal phase sequence is a, b, c.
E_a, E_b, E_c = line-to-ground voltages at point of fault.
E_{ab}, E_{bc}, E_{ca} = line-to-line voltages at point of fault.
E_G = generated positive-sequence voltage of phase a, at the source; when several machines are involved, this becomes an equivalent generated voltage. (*Studies of Transmission Stability*, by R. D. Evans and C. F. Wagner, A. I. E. E. TRANS., 1926, Vol. XLV, pp. 73 and 79.)
E_1 = positive-sequence voltage at point of fault.
I_a, I_b, I_c = line currents at point of fault.
I_g = ground current at point of fault. ($= 3\ I_0$)
I_0 = zero-sequence current at point of fault.
R = fault resistance.
R_g = fault resistance affecting directly the flow of ground current of a double-line-to-ground fault.
R_L = fault resistance in each of the faulted phases of a double-line-to-ground fault.
R_0 = zero-sequence resistance (per phase).
R_1 = positive-sequence resistance (per phase).
R_2 = negative-sequence resistance (per phase).
X_0 = zero-sequence reactance (per phase).
X_1 = positive-sequence reactance (per phase).
X_2 = negative-sequence reactance (per phase).
Z_0 = zero-sequence impedance (per phase).
Z_1 = positive-sequence impedance (per phase).
Z_2 = negative-sequence impedance (per phase).

NOTE: All currents, voltages, and impedances listed above are scalar quantities; an inverted circumflex ($\check{E}_g$) above any symbol indicates the vector form, which may be expressed in terms of complex numbers.

The titles and legends make the curves practically self-explanatory. (A list of symbols is given in Table I.) Voltages and currents at the fault location are shown in Figs. 3 to 7 inclusive. In Fig. 3 all resistances are taken equal to zero, voltages and currents being plotted as functions of the sequence reactances. Since in a resistance-grounded system the zero-sequence resistance is an important factor in Figs. 5 and 6 this is taken as a variable. In these two illustrations only the curves for the case of positive- and negative-sequence reactances being equal ($X_1 = X_2$) are given here. Positive- and negative-sequence reactances are equal for symmetrical static networks, but rotating

---

machines in a system may cause these reactances to differ. Table II summarizes the ranges of voltages and currents shown in these figures.

TABLE II—RANGE OF FAULT CURRENTS AND VOLTAGES

Type of fault	Current ratio* Line	Current ratio* Ground	Voltage ratio *L-G*†	Voltage ratio *L-L*‡
L-L	0.69—1.15		0.67—1.20	0.58—1.04
L-G	0.00—2.00	0.00—2.00	0.58—1.97	0.67—1.20
2*L-G*	0.69—2.02	0.00—3.00	0.00—1.80**	0.00—1.04**

Based on $\frac{R_1}{X_1} = \frac{R_2}{X_1} = 0 \qquad 0 \leq \frac{R_0}{X_1} \leq \infty$

and $\frac{X_2}{X_1} = 0.5 \text{ to } 1.5 \qquad 0 \leq \frac{X_0}{X_1} \leq \infty$

*Reference is the three-phase short-circuit current.

†Reference is the normal line-to-neutral voltage.

‡Reference is the normal line-to-line voltage.

**These voltages are identical; only the line-to-ground voltage curves have been plotted.

One of the most important facts brought out by these curves is that the line-to-ground voltage may rise to a value of 190 per cent of normal (somewhat greater than the normal *line-to-line* voltage), a fact not generally appreciated. It is interesting to note that the ratios of line and ground current to the three-phase short-circuit current may be as great as 1.5 and 3.0, respectively; also, that the ground current of a double-line-to-ground fault may be much greater than the maximum value of a single-line-to-ground fault. Some of these values are still greater for cases (not shown here) where the negative-sequence reactance is not equal to the positive-sequence reactance.

It is pertinent to say (as the curves show in part), that generally the maximum values of fault currents are obtained with low values of zero- and negative-sequence *reactances*; and correspondingly, that the maximum values of voltages occur with high values of zero- and negative-sequence *reactances*; for zero-sequence *resistance* (R_0), however, such is not the case; maximum values of currents and voltages are obtained mostly with intermediate values of R_0. Also it may be noted that the adding of zero-sequence resistance to a system having no resistance increases the line current on a double-line-to-ground fault; consequent increase of this resistance reduces line currents as well as ground currents, but increases line-to-ground voltages.

SYSTEM PERFORMANCE

From the foregoing it is evident that two systems of the same voltage having identical values of three-phase short-circuit current for particular fault locations may have radically different voltages and currents for *unbalanced* faults. Line currents are important because of the mechanical stresses which they set up in rotating machines, transformers, reactors, circuit breakers, and bus structures. High voltages are important because of the stresses produced by them on apparatus or line insulation, as well as on lightning arresters. In circuit-breaker and relay applications combinations of voltage and current are important. Certain applications require consideration not only of the symmetrical effective values of voltages and currents as given but of asymmetrical components, machine harmonics, and high-frequency oscillations resulting from stored energy changes. Some aspects of certain general system problems will be discussed briefly:

The general classification of systems with respect to grounding is (1) ungrounded, (2) grounded through

impedance (resistor or reactor), and (3) free neutral.

(For the purpose of this classification, a system grounded through neutral reactance resonating with line capacitance may be viewed as a free-neutral system, since the object of the reactance is to nullify line capacitance; in this paper the phenomena of arcing grounds is not treated, and in general the grounding impedances are assumed to be so low that arcing grounds are avoided.)

It is a fact, however, that actually the zero-sequence impedance of a direct-grounded system may be higher than that of a system of similar capacity and extent which is grounded through a neutral impedance of low value. Obviously, the classification given is unsatisfactory since it takes into account only the impedance between ground and neutral points of certain pieces of apparatus, instead of the total effective zero-sequence impedance which includes line and apparatus impedance as well as that of grounding resistors and reactors.

A much more accurate classification of systems with respect to grounding is suggested by Figs. 3 to 6. The curves as given cover the full range of system grounding from a direct-grounded system to a free-neutral system, and suggest that *the ratio of zero-sequence impedance to positive-sequence reactance be used as a criterion or measure of the "degree of grounding,"* low values of this ratio corresponding to a solidly-grounded system and high values to a free-neutral system. Hence, the criterion is not one by which to determine whether there is an impedance between one or more neutral points and ground but, more accurately, whether the ratio of zero-sequence reactance or resistance to positive-sequence reactance is high or low. For convenience this ratio is called the "zero sequence impedance ratio."

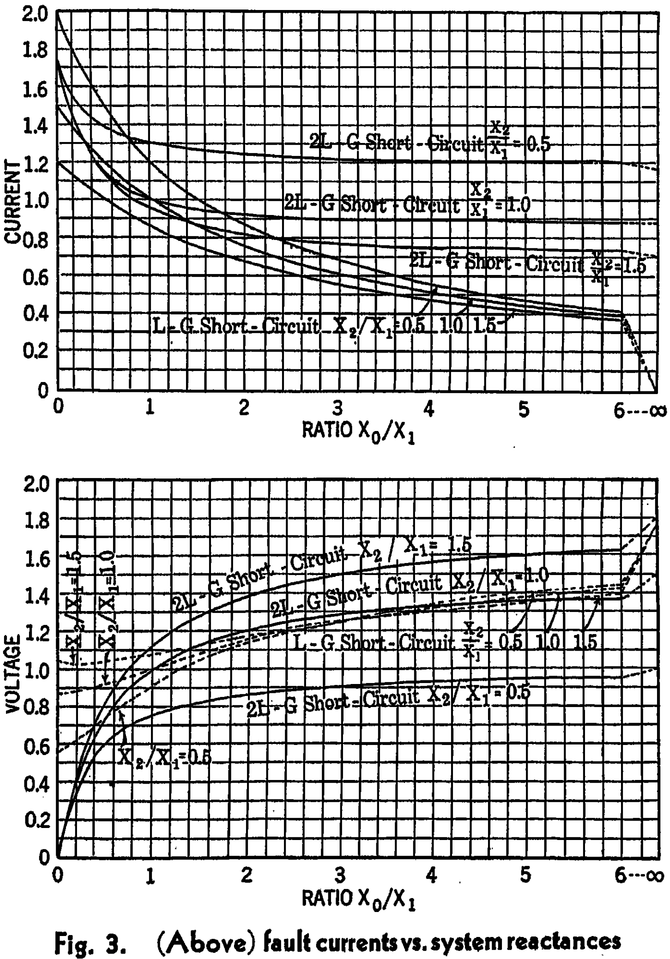

Fig. 3. (Above) fault currents vs. system reactances and (below) fault voltages vs. system reactances for single- and double-line-to-ground faults

Currents (above) are expressed as a ratio to the three-phase short-circuit current. Voltages (below) are line-to-ground values and are expressed as ratios to the normal line-to-neutral voltages. $R_1 = R_2 = R_0 = 0$ in all cases

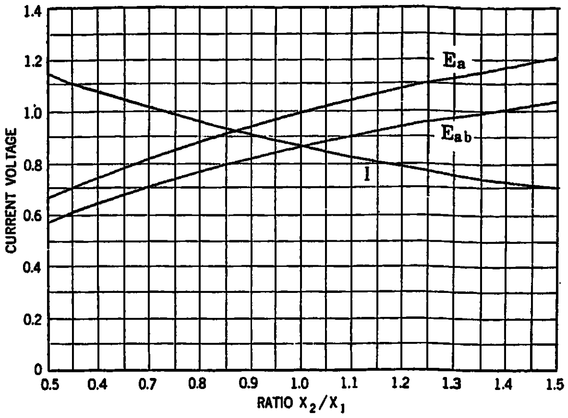

Fig. 4. Fault current and voltages vs. system reactance for line-to-line fault

Current is expressed as a ratio to the three-phase short-circuit current; voltages are expressed as ratios to their respective normal values

Various methods of grounding a system have rather complicated effects on stability limits. Decrease in positive-sequence voltage may cause an underexcited and overloaded synchronous machine to pull out of step without causing the system as a whole to lose synchronism. At various times it has been suggested that the positive-sequence voltage at the fault location is a measure of the stability of a system under fault conditions. Accordingly, Fig. 7 has been plotted to show the range of this voltage for single- and double-line-to-ground faults respectively. Voltage is plotted as a ratio to the normal line-to-neutral voltage, and impedances are expressed as ratios to the positive-sequence reactance.

CIRCUIT-BREAKER OPERATION

The effective current flowing through a pole of the breaker before it opens, and the effective voltage occurring across that pole after opening are used often as a measure of the duty imposed in opening a short circuit. It should be clearly realized that this measure does not take all factors into account. Dr. Joseph Slepian has pointed out that the most significant factor is the rate of restoration of voltage at the instant at which the current passes through zero.

The phenomenon of arc extinction has been likened to a race between the build-up of voltage, and the deionization of particles in what was the arc stream before the arc was extinguished. Recovery voltages are affected by the presence of asymmetrical currents,

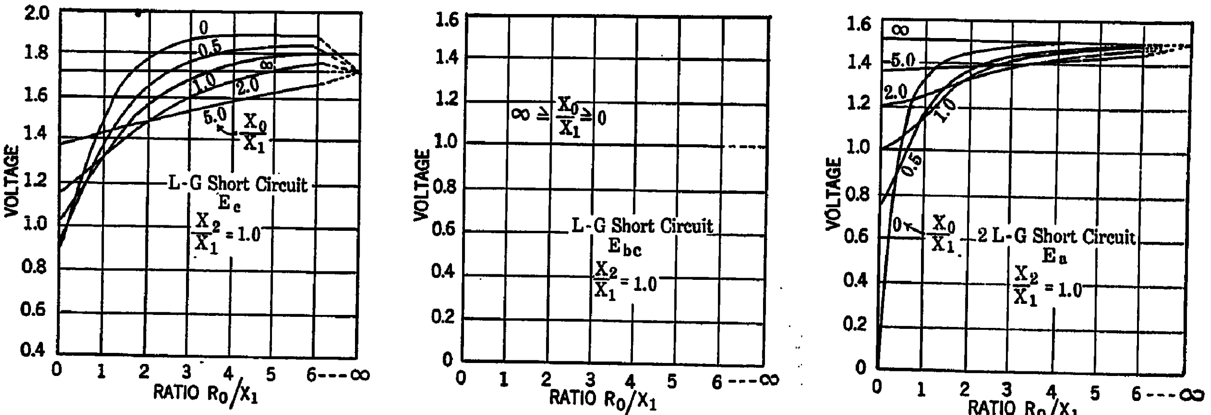
Curves in each group are for various values of the ratio X_0/X_1. All currents are expressed as a ratio to the three-phase short-circuit current



Line-to-ground voltage for single-line-to-ground fault

Line-to-line voltage for single-line-to-ground fault

Line-to-ground voltage for double-line-to-ground fault

Fig. 6. Fault voltages vs. system impedances for different types of faults

Curves in each group are for various values of the ratio X_0/X_1. All voltages are expressed as ratios to their respective normal values

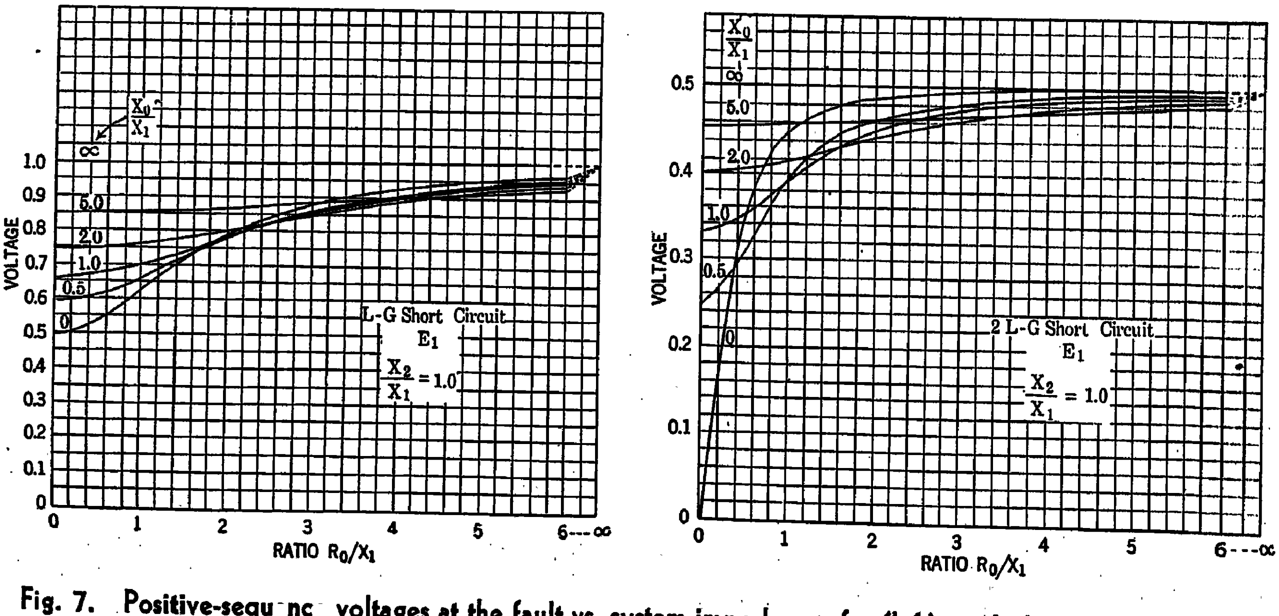


Fig. 7. Positive-sequence voltages at the fault vs. system impedances for (left) single-line-to-ground and (right) double-line-to-ground faults

Curves in each group are for various values of the ratio X_0/X_1. All voltages are expressed as ratios to the normal line-to-neutral voltage machine harmonics, and high-frequency oscillations, but any of these may either increase or decrease the rate of restoration of voltage; hence, it probably is true in comparing two similar systems of the same voltage and equal three-phase short-circuit current that the system with the highest effective recovery voltage for fault conditions will have the highest rate of change of voltage at the critical point of the wave. Regardless of whether the product of the effective current before the pole opening and the effective voltage after the pole opening may be taken as a measure of breaker duty, this product appears to be suitable as a measure of the influence of the sequence impedances on circuit breaker duty.

For the various steps possible in the clearing of the different types of faults the aforementioned product has been computed and plotted in Fig. 8. This product is obtained from the curves of Fig. 3. For example, with a three-phase grounded short circuit, the opening of the first pole changes the fault from a three-phase to a double-line-to-ground fault and the product is of the three-phase short-circuit current and the voltage of the double-line-to-ground fault. The ordinate of Fig. 8 is the ratio of the product of voltage and current for a particular pole to the corresponding product of the three-phase short-circuit current and the normal line-to-neutral voltage; the abscissa is the ratio of zero-sequence to positive-sequence reactance. For the sake of simplicity all resistances have been assumed as zero and curves are shown only for the case of positive- and negative-sequence reactances being equal.

The curves of Fig. 8 indicate that under some conditions any tendency for one pole to open before the others becomes augmented as a result of the increased duty imposed on the last poles to open (regardless of the fact that the breaker may be in proper adjustment). This may be compared to a state of unstable equilibrium. The following points are salient: (1) when zero-, positive-, and negative-sequence reactances are equal the circuit breaker kva. per pole is independent of the type of fault or the sequence of opening; (2) for any other ratio of zero-sequence to positive-sequence reactance the maximum kva. per pole is increased for some one step in the sequential opening of a breaker on a three-phase fault. Thus there may be a wide range of values of the kva. per pole when clearing faults, depending upon the type of fault, sequence of pole opening, and the sequence impedance ratios.

Comparison of Grounding Methods

The previous analysis shows definitely that the fault voltages or currents may be taken as factors indicative

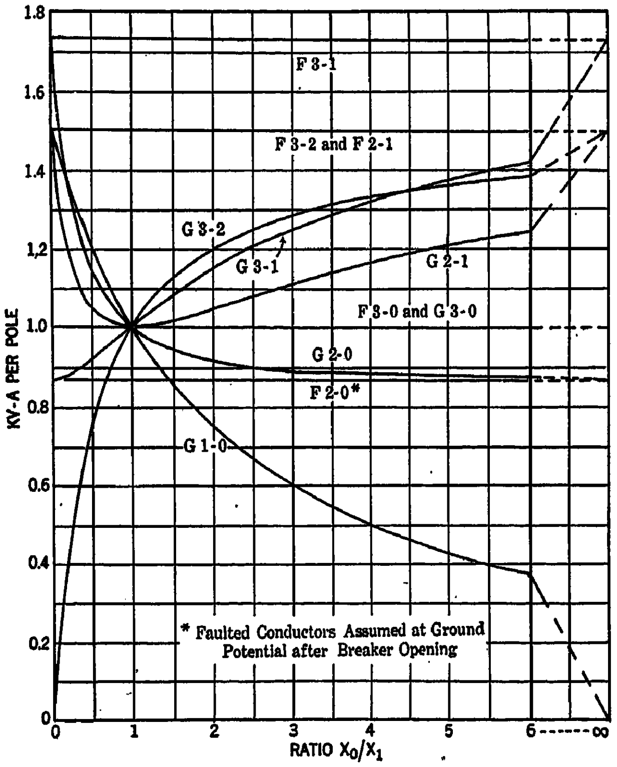

Fig. 8. Circuit-breaker kva. vs. sequence reactances for $X_1 = X_2$

Each curve shows the kva. for a pole the opening of which is one particular step in clearing a fault; curve labeling indicates number of poles closed both before and after this opening, and whether fault is grounded or free from ground (*G* or *F*). Ordinates are ratios of the product of the symmetrical r. m. s. current through a pole before opening and the voltage after opening, to the product of the three-phase short-circuit current and the normal line-to-neutral voltage. All resistances are taken equal to zero

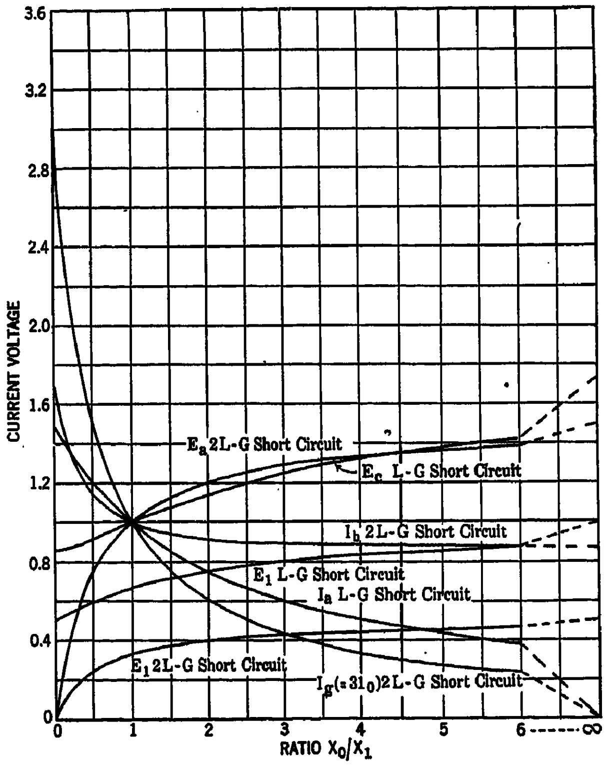

Fig. 9. Typical curves for system grounding study. Fault currents and voltages vs. zero-sequence reactance ratio for system in which $X_1 = X_2$ and all resistances are negligible

Ordinates are fault currents and voltages; currents are expressed as ratios to the three-phase short-circuit current; voltages as ratios to the normal line-to-neutral voltage. These curves were derived directly from Figs. 3, 4, 5, 6, and 7 of certain aspects of system performance, and that they are determined mainly by the value of the zero-sequence impedance ratio. Obviously a preferred value of this ratio depends upon the weight given to the various factors and upon the particular system involved. Fig. 9 illustrates the use and value of the foregoing analysis as applied in a study of system grounding. It is important to note that (1) as the ratio of zero-sequence to positive-sequence reactance varies from 0 to 1, the disadvantages decrease and the advantages increase while, (2) as this ratio goes above 4 there is relatively little of either gain or loss. Hence, the *preferred range of the zero sequence impedance ratio appears to be from 1 to 4.*

Fundamental Basis for Distance Relaying

For single-line protection, with the exception of pilot-wire, or superposed high-frequency methods, distance relays form the nearest approach to the theoretically ideal system. Except for errors due to fault resistance, these relays operate accurately according to the relative distance to faults.

AN IDEAL SYSTEM of relays for the protection of a sectionalized transmission line is one capable of dividing into two classes all faults on the lines it protects; in one, those faults occurring between the relay and the next sectionalizing point; and in the other, all other faults. It should also be capable of making this classification instantaneously. If a fault falls into the first class, the circuit breaker may be tripped immediately, thus reducing damage at point of fault and shock to the system; in general, permitting operation nearer the stability limit. If the fault falls in the second class, the circuit breaker would not be tripped or tripped only after a time delay which is great in comparison with the time required for breaker operation.

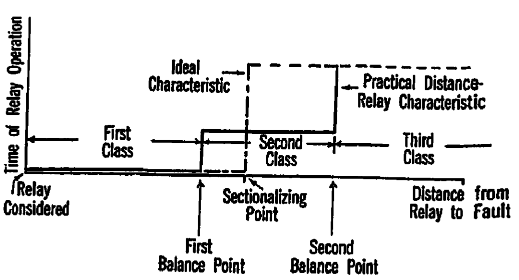

Fig. 1. Ideal and practical characteristics for distance-relaying systems

Exclusive of pilot wire or superposed high-frequency methods, the closest approach to this ideal for single line protection is attained by the use of distance relays. For parallel-line protection a somewhat closer approach to the ideal has been obtained by balanced-current relays; but additional protection is required for single-line operation and to care for the possibility of simultaneous faults on both lines, for this distance relays are well suited. Hence, if the distance relays can be made sufficiently accurate and rapid, the use of the balanced-current relays is non-essential.

Since distance relays cannot indicate with 100 per cent accuracy the distance to the fault, an additional intermediate class of faults must be introduced (see Fig. 1) comprising those which occur near the end of the section on both sides of the sectionalizing point. If a fault falls into the intermediate class, there is introduced a time delay sufficient to allow a breaker at the next sectionalizing point to trip in response to its relays which operate instantaneously; if the fault is just beyond the next sectionalizing point, it will fall into the first class of faults for the relays located at that point, and the fault will be cleared by the opening of the breaker at that point, allowing the first relay to reset; if the fault is just within the section, the relay at the original station will operate at the expiration of the time delay. Thus the final classification of faults falling in the intermediate class is made with the assistance of other breakers and relays.

In order to strike the boundaries of the intermediate class, it is convenient to call the points at which faults must occur "balance points," since the relays must just balance between one type of operation and another for faults at these points.

Distance relays may be of either the impedance or reactance type, operating on the indicated impedance or reactance of the circuit from the relay to the fault, obtained by comparing the voltage and current at the relay location. These indicated impedances and reactances are approximately proportional to the distance from the relay to the fault. They do vary somewhat,

---

From "Fundamental Basis for Distance Relaying on Three-Phase Systems," (No. 31-61) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

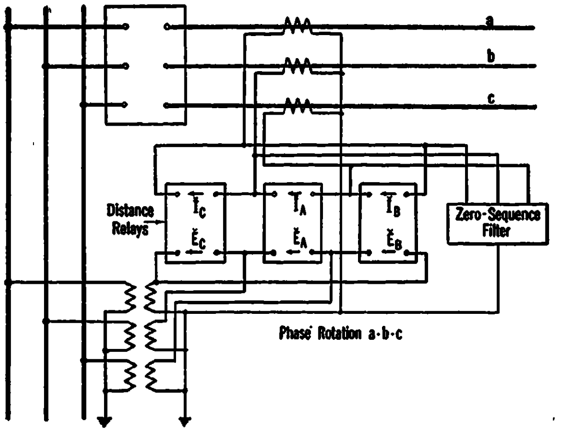

Fig. 2. Improved distance-relay connections for line-fault protection using delta-connected relays and zero-sequence filter

however, causing the locations of the balance points to shift accordingly. The greater the variation in balance point location, the larger the intermediate class must be made, and the greater are the departures from the ideal protection. If the variations in balance-point location are too great, this type of protection cannot be applied. It is, therefore, important to determine the causes of this shift in balance point and to develop methods of reducing or eliminating it.

For protection against line faults involving two or more line conductors, conventional relay connections make use of the line-to-line voltage and the line current which lags the voltage by 30 deg. at unity power factor. Analysis shows that both the indicated impedance and reactance are subject to variations for a fault in a given location dependent upon the fault resistance, current feeding the fault from the opposite end of the section, current in the remaining conductor, and current in the earth or other grounded paths. Variations in the balance points are, therefore, due to the same causes. Further analysis reveals that if "delta currents" obtained either by connecting the current transformers in delta or the current windings of the relay in delta with a suitable zero-sequence filter are used for relaying, (see Fig. 2) the two latter causes of variation are eliminated.

For protection against faults involving ground, conventional relay connections make use of line-to-ground voltage and line current. An analysis of this type of fault shows that the indicated impedance and reactance are subject to variations due to the fault resistance, the current feeding the fault from the opposite end of the section, the current in the other conductors, the mutual impedance between two parallel lines, and the difference between the impedance to balanced three-phase currents, or positive-sequence impedance and the impedance to balanced ground current or zero-sequence impedance. Further analysis shows that all of these effects except the first two may be substantially compensated, so that variations are produced only by fault resistance and the fault current feeding the fault from the opposite end of the section. This compensation may involve modifying either the current or the voltage in proper proportions. (See Figs. 3 and 4)

Thus, by the use of suitable methods, either the impedance or reactance type of distance relay for either line or ground faults may be made to measure accurately

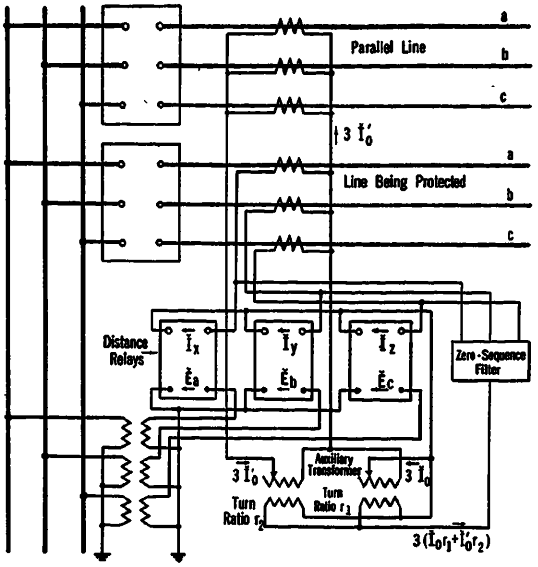

Fig. 3. Improved distance-relay connections for single-line-to-ground faults using current compensation

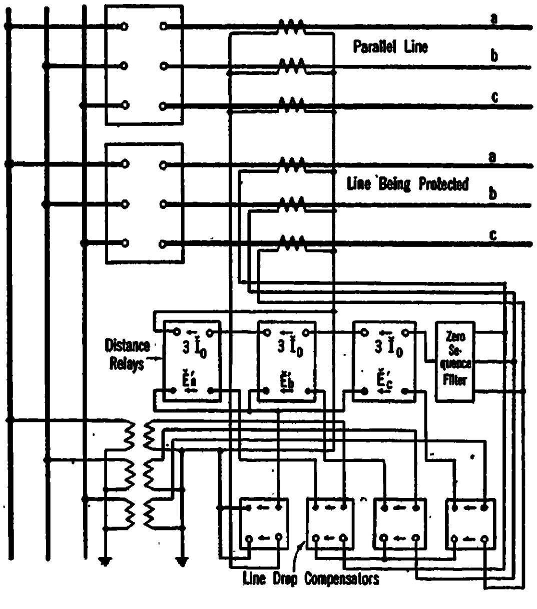

Fig. 4. Improved distance-relay connections for single-line-to-ground faults using voltage compensation

the distance to the fault except for the effects of fault resistance, the current from the opposite end of the section affecting the relays only when fault resistance is present. The effect of fault resistance may be represented by adding vectorially to the proper line impedance a resistance equal to the fault resistance, and a second term equal to the fault resistance multiplied by the vector ratio of two currents, these latter being functions of the currents feeding the fault from the two ends of the section, or their symmetrical components. Since the line impedance is generally principally reactive, the two resistance terms will add approximately at right angles, thus causing only moderate increases in the magnitude of the sum, unless the resistance terms are very large. The impedance relay operates on the magnitude of the sum of the three terms. This increases slightly with increasing fault resistance, and causes the balance points to shift toward the relay. On the other hand the reactance relay operates on the reactive component of this vector sum, and is therefore unaffected by the first fault-resistance term. If the two currents involved in the ratio are not in phase, the second fault-resistance term will have an apparent reactance which may be positive or negative depending upon which current is leading, so that the balance point may be shifted in either direction. Although generally the shift will be smaller than that produced by the same resistance using an impedance relay, the fact that it may be in either direction must be taken into account. Where fault resistances are moderate, as on most line faults if cleared rapidly, the total variation in balance point will often be quite comparable for the two types of relays. On ground faults the fault resistances are generally higher, so that some form of relay which is substantially independent of resistance is generally required, and accuracy thus reduced.

It should be pointed out that the design of the relay, its simplicity, reliability, and speed of operation, as well as possible accuracy, must be considered in choosing the type of distance relay to be used for a given protection.

From this analysis the following conclusions may be drawn:

1. Conventional methods of distance relaying are subject to errors other than those caused by fault impedance.

2. These errors may be eliminated in relays protecting against line faults by the use of "delta relaying," obtained either by connecting the current transformers in delta or by connecting the current windings of the relays in delta, using a suitable zero-sequence filter.

3. These errors may be eliminated in relays protecting against ground faults by the use of current or voltage compensation, and therefore if the impedance of the section being protected is sufficiently great distance relaying is suitable for ground fault protection.

4. Errors introduced by fault impedance, comprise the chief limitation in the application of distance relaying, but these decrease with increasing section impedance. This limitation affects distance relays of both the impedance and reactance types, although to different extents.

5. Distance relaying may be made to approach even more closely the desired relaying ideal, and within the limits of its application it should give satisfactory protection regardless of generator capacity or system conditions.

Shallenberger Personal Memoranda Discovered

A MEMORANDUM of Oliver B. Shallenberger, personally handwritten, and recently come to light, gives an interesting glimpse of the electrical business forty years ago. The man who left this penciled notation was one of the pioneer electrical engineers of the then infant Westinghouse company and was active in many major projects that did much to shape the course of the industry.

A young man when he first entered the electrical industry from the Navy after a course at Annapolis where he specialized in physics and electricity, he was still a young man when he died at the age of thirty-eight after fourteen years of creative effort.

His invention of the meter was in 1888 under very unusual circumstances and at a time when at least one justifiable criticism of alternating current was that there was no meter for measuring it and no motor to be used with it. In assembling a new form of arc lamp for test, a small spring dropped down between an actuating coil and an iron core; Shallenberger, standing near, noticed that the spring began to turn slowly and he restrained the attendant from picking it up with, "Let's see what makes the spring revolve." He saw and exclaimed, "There's a meter in that—and perhaps a motor!"

Shallenberger was at that time 28 years old. In 1889 he was sent abroad by his company to study European central stations. In 1891 he resigned because of ill health and spent several winters in Colorado, a victim of tuberculosis.

While in the West he conceived the idea of transmitting power from Canon City to the famous mining camp at Cripple Creek. In 1890 he had helped to promote the Telluride project of carrying power three miles—a revelation at that time; in 1897 he formed the Colorado Power Company of which he was president until his death.

Part of the time after his resignation was spent working in his own laboratory in Rochester, Pennsylvania, and it was there that he studied the Cripple Creek transmission and made the notations that have been discovered.

On one side of the memorandum are listed machines and equipment with prices, weights, and freight costs which form an interesting comparison with modern apparatus. Three 470-kw. dynamos are priced at $9,000 each and weighed 37 tons. Present-day machines of corresponding rating would cost about $6,500 and weigh 17.5 tons. A lightning arrester of the type he priced at $178 would cost now only about $75.

On the reverse side of the same memorandum are notations pertaining to rates and data on an expected electric lighting load, "current 28c. kw-hr., arc lamp at $15 a month," etc.—*Contributed.*

Power Supply for Telephone Service

Automatic regulating and control equipment is finding increasing use in telephone power plants, giving more exact performance, increased reliability and reduced maintenance. Certain regulating equipment and a few of the unit-type automatic power plants recently developed are described.

By

Bell Tel. Laboratories, Inc., New York

CONTINUITY and reliability of service have been keynotes guiding development of telephone power plants for many years. Duplicate equipment, reserve storage batteries, and emergency sources of power supply are regularly provided as required. A review of data available in some metropolitan districts indicates that a high percentage of continuous performance has been obtained during the past twenty years, exceeding 99.999 per cent of full time.

Provision for quick change from regular to reserve units is required, of course, while voltage regulation of the d-c. supply and frequency regulation of signaling machines are necessary for proper performance of the telephone equipment. These requirements point to the use of automatic regulating equipment and automatic power-plant operating arrangements to as large an extent as practicable, particularly since continuous service must be maintained both day and night.

Installations of automatically-controlled power equipment in small telephone offices at several towns in Pennsylvania were made during 1917 to make continuous attendance by plant employees unnecessary, particularly over week-ends. Signaling hydrometers in the two main storage batteries controlled an automatically started mercury arc rectifier to recharge the batteries as necessary. Alarms were provided to indicate any failure of equipment or abnormal discharge.

Modern automatic power plants in small offices follow somewhat similar lines except that rectifiers of the hot-cathode tube type or the dry copper-oxide disk type are employed, and control of charging is by means of an improved type of ampere-hour meter. Control of output voltage is frequently by relays which introduce counter cells. For larger offices is employed motor-generator equipment controlled by an ampere-hour meter, or where continuous floating at a fixed voltage is used, by various other means to bring in additional generators when the load requires them, most of the latter being still upon a trial installation basis.

The considerable variations in load current which must be furnished by the power plant are illustrated in Fig. 1, which pictures the daily load cycles in offices of several classes. Although the power required to carry a voice current over a telephone line is surprizingly small, it is not realized sometimes that the equipment necessary to accomplish this and to operate mechanical switching devices, signaling lamps, and other equipment in large offices with much traffic is considerable.

In Group *D*, (Fig. 1) for example, two-thirds of a million calls were handled during the day by three metropolitan office units operated from one power plant. Group *E* with a peak of 5,300 amperes at 24 volts represents the load of long distance switchboards and repeaters distributed over ten floors, this load being supplied by motor-generator sets having combined capacity of 10,200 amperes while the storage battery has a rating of 34,880 ampere-hours and weighs 111 tons. Some 500 hp. is required to drive these generators, while an additional 300 hp. is provided for 130-volt telegraph and repeater plate generators not shown on this group. An additional 215 hp. is provided for a vacuum-tube system to handle message slips. Part of the installed horsepower is on reserve equipment. Two other telephone power plants are in the same building. It might be mentioned that primary power is purchased from the public service companies and nearly all of it is then converted into other forms suitable for telephone use.

A brief statement of the means employed for regulating the voltage of the main d-c. power supply may be of interest, since this has assumed considerable importance from the standpoint of proper circuit operation, especially in dial offices where the automatic-switching equipment requires regulated power, and in repeater offices where the vacuum-tube amplifiers must have regulation to insure uniform transmission gain and long life of tubes.

Many years ago a single-battery group was employed, and when the output voltage was regulated, counter-e. m. f. cells were cut in during battery charging and at other times when necessary. With the adoption of duplicate batteries and the continuous floating system under which all the current is supplied to the load from the generators while batteries are held in standby service, an improvement in voltage regulation was obtained, the normal daily variation of a 24-volt battery being reduced from about seven volts to two volts. To reduce the two-volt range obtainable with hand adjustment of the generators, an automatic voltage regu-

lator having several novel features was developed. One of these regulators with case open is shown in Fig. 2.

Commercial regulators available were not found satisfactory in this service since considerable "hunting" resulted from the slow response of voltage in a floated storage battery to changes of current flowing into it. This regulator includes a solenoid-operated voltage element contacting at intervals with a cam disk driven by a synchronous clock motor. The contacts are made for short periods at intervals of ten seconds, the duration of contact varying with the amount that the main-battery voltage is deviating from normal. A reversible motor drives a rheostat which varies the field excitation of the charging generator. This regulator is usually adjusted to maintain the voltage on the service bus-bars within about ± 0.15 volt. Simpler types of regulators are used on smaller installations.

Typical Unit-Type Automatic Power Plants

In the development of these plants the smaller and less complicated plants were naturally attempted first; those for small private branch exchanges of the dial type, which were required in considerable number, received early attention. The dial exchange has no operators and everything must be done mechanically or, more properly, electrically, obviously requiring a more complex power plant than that of the manual P. B. X. or even of the small manual central office. In addition to a source of direct current which will continue reliable during short periods of power failure and which will be regulated as to voltage, it is necessary to provide alternating current for ringing telephone bells; also a variety of tones and signals for information and supervisory purposes. A plant which is typical of several types developed for this general class of work is shown in Fig. 3. The plant is assembled as a unit with batteries in the lower cabinet and control equipment including fuses, meters, switches, relays, ringing ma-

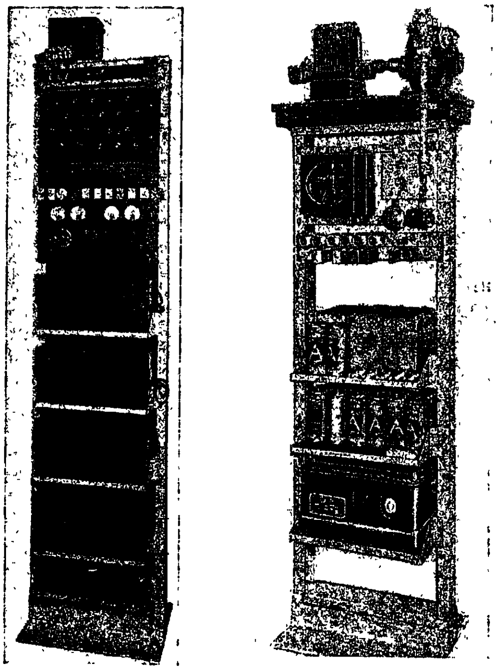

Fig. 4. (Left) Typical small plant for supplying vacuum-tube plate circuits; 125-135 volts, 50-200 milliamperes. (Right) Small plant for ringing and transmitter supply; 75-100 volts, 20 cycles and 8.5 volts direct current, 20 or 40 ampere-hours

chine, and automatic voltage control in an upper cabinet; the charging rectifiers are mounted above. In small plants the single rectifier is mounted within the cabinet. Storage batteries are of a type assembled in groups of three cells in a glass case and are equipped with indicators to show the approximate condition of charge.

Counter e. m. f. cells used for voltage control in the small plants having but a single battery are of a new type using nickel electrodes and alkaline solution. Neither plates nor solution are affected chemically during operation, so that the maintenance consists largely in adding water to replace electrolysis loss. The small panel-mounted ringing machine is of the inverted rotary-converter type with motor element operating upon the battery and the a-c. output fed to a step-up transformer arranged to give the proper operating voltages at about twenty cycles. This machine has automatic control, starting when a receiver is lifted from the switch hook and stopping after completion of the call. It is equipped with jack-and-plug connections for ready replacement by a spare machine when maintenance is required.

In this plant the charging equipment is arranged for continuous operation at an output which will carry a large percentage of the busy-hour load and will return to the battery during the light-load periods whatever discharge has been taken plus additional current to offset battery loss. A sensitive voltmeter-type relay actuating a solenoid-type switch automatically cuts in or out the counter cells to keep the terminal voltage within a proper range. One or two three-ampere rectifiers of the hot-cathode type are provided as required.

Several plants have been designed to supply energy economically to plates and filaments of repeater tubes, and to other equipment when such energy is not available from regular central office power plants. In order to match more nearly the appearance of the repeater equipment with which these are usually associated, the equipment is mounted on floor-supported vertical channels, which carry shelves and panels. Enclosing covers are being developed for use in locations where appearance will justify the added expense or where additional protection is desirable.

Several small 130-volt plants having a range in capacity from 50 to 80 or from 50 to 200 milliamperes, and larger plants. with a capacity range from 5 to 20 amperes, are included in this series, of which a typical one is shown in Fig. 4. The smaller equipments use copper-oxide rectifiers and reserve batteries of block-type dry cells automaticaly connected into circuit upon failure of the regular power service. An unusual arrangement is employed, the dry cells being connected across the rectifier in series with a copper-oxide disk assembly acting as a valve which permits a very small current to trickle into the cells under normal conditions and interposes but little resistance when the cells pick up the load, automatically sending the current in the reverse direction during power failure.

The larger sized plants use small storage cells as reserve and also use rectifiers of the hot-cathode type. A 24-volt, 8-ampere plant for filament supply is likewise available, and similar plants of other ratings are in process.

Where current demands are heavier, the amount of energy involved and the sizes of batteries warrant the use of ampere-hour meters to start and stop the rectifiers automatically upon a schedule which insures that most of the day's load is carried directly by the charging equipment and that the reserve battery is usually maintained with from 80 to 90 per cent of its capacity available for emergency use. In addition to control contacts and adjustable overcharge shunt, the ampere-hour meter is provided with a thermocouple to increase light-load accuracy, this having been found necessary because during a considerable part of the 24-hour cycle at night the load upon the office is very small. Several sizes of plants of from 5- to 100-ampere capacity at 24, 34 or 48 volts, have been made available.

Four plants have been developed in small and compact shape to furnish economical and automatic ringing and signaling service to outlying offices, particularly of the "magneto" type in districts where subscribers' telephones have their own local batteries. One of these is shown in Fig. 4.

Ringing current is obtained from a motor-driven magneto generator except during failures of outside power when a vibrating-type ringing interrupter operated from dry cells is automatically brought into use. A small storage battery equipped with a copper-oxide rectifier in operation continuously furnishes direct current for the transmitters of the central office operators, this unit being shown upon the lowest shelf.

Larger ringing plants employing two motor-driven generators equipped with a system of interrupters to furnish machine ringing, supervisory tones, and signals, as well as positive and negative direct current for operating coin boxes, have also been developed as completely engineered and coded equipment. The regular set operates from outside power while the emergency set runs on the central office storage battery. Such equipment for a smaller office is shown in Fig. 5.

Automatic-control equipment is so arranged that the emergency set will start upon failure of ringing current from the regular set and all office ringing and signaling circuits will be automatically transferred to the reserve machine by means of 12-pole, electrically-operated switches. The frequency and voltage are automatically controlled and provision is made for return to normal condition as soon as the emergency has passed. Some of the several types of signals provided by these machines utilize interrupted battery current, making slight sparks, so that these interrupters are equipped with radio-frequency choke coils to prevent interference with nearby receiving sets. Later tone alternators of a novel inductor type which cause no interference are also available, together with low-speed interrupters of new design in which the current contacts are made and broken by mercury rolling in cast-iron channels containing an atmosphere of nitrogen.

Some unusual unit-type coded plants with automatic or semi-automatic features have been developed for special uses; only one of these, however, will be mentioned here, namely, the automatic ground-potential compensator for telegraph circuits in telephone offices. This plant, including a regular and a reserve motor-generator set, is arranged to provide a buck-or-boost voltage up to 100 volts or thereabouts in the common telegraph ground lead of an office having this equipment. It is used where unfavorable electrical and geologic conditions cause the local ground potential to fluctuate severely. The machine is controlled by a sensitive high-frequency relay connected over a pilot wire to a neutral ground several miles distant.

OPERATING EXPERIENCE

Some of the automatic-control equipment mentioned has given satisfactory service for several years, but the completely automatic plants of the present types are of recent development. Operation during a few years has been quite satisfactory; any delays under automatic control in general are less than with manual operation, while attendance of course is very greatly reduced. Alarms are provided to secure help from an attended office in the event that any of the automatic equipment should fail to perform or unexpected emergencies should develop. Success with the smaller plants described has led to installation of larger plants upon a trial basis and these also are performing satisfactorily.

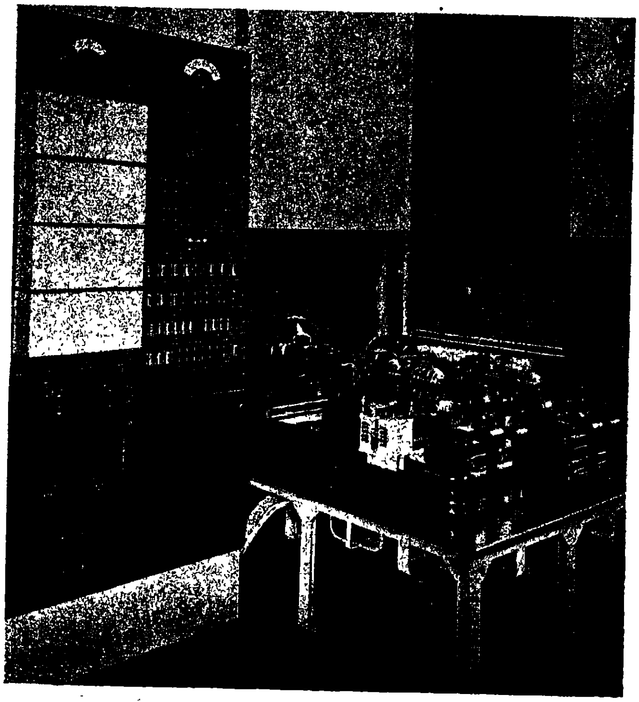

Fig. 5. Power plant for ringing and coin control, 105-100-85-77 volts, 1-8 amperes, 20 cycles and + 110, − 110 volts, 0.25-0.50 amperes direct current

Helical Grooves In Slip-Rings and Commutators

Current-collection problems can be simplified to a marked degree by helical grooves cut into the surfaces of commutators and slip-rings. Results of comparative tests before and after grooving are presented herewith.

By
G. M. LITTLE
Member A. I. E. E.

Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

PERFORMANCE OF BRUSHES on slip-rings and commutators is dependent on many more or less obscure conditions. Some of these are fairly well understood and are under control so that for the most part it is pretty well known what current density, spring pressure, peripheral speed and grade of brush are best for a given brush application. There are many purely mechanical conditions that are undesirable, such as loose commutator bars, worn bearings, poorly balanced armatures, rough tracks (in traction service), friction, vibration, and loose connections; also there are dirt, oil, acid fumes and many other obstacles which influence good brush performance. In addition to these disturbing factors, however, it often is found that the current is not divided evenly between parallel-connected brushes, and this causes some of them to be overloaded.

This article is an account of an investigation into some of the causes of trouble existing right at the sliding contact, and of the series of tests conducted on helically grooved slip-rings and commutators which followed. The results show conclusively that (1) a more uniform current distribution is obtained, (2) local spot heating and glowing under overload conditions are eliminated, and (3) better commutation with cooler operation and longer brush life is assured, where these grooves are employed.

If the current density is high, a brush is likely to glow and throw off white-hot streamers, this glowing manifesting itself as a small stationary or slow-moving white-hot spot in the polished surface of the brush. Of course it cannot be seen directly, but the surrounding brush material becomes heated to a good red color 1/8 of an inch in all directions and if the small white-hot spot is near the edge of the brush, the red glow of the surrounding brush material can be seen readily.

A study of this glowing confirms the correctness of the usual explanation of the cause which is based on the negative resistance-temperature coefficient of carbon. If a brush is overloaded and one part of the brush face should by chance be a little warmer than another part, the current will have a tendency to crowd into this warmer area, raising its temperature more and more until a low-resistance hot spot is developed, which then carries substantially all of the current.

It has been observed that a hot spot of this kind will remain in one location on the brush face for many hundred revolutions of a commutator or slip-ring, during which time all sparking of the brush will be stopped. This tendency of a spot to take all the current and hold to one position on the brush face is promoted further by the local expansion of the hot carbon. This expansion causes the hot spot to become raised slightly above the polished surface and the brush rides on this "hill" until it is worn down. During this time most of the spring pressure is concentrated on the minute, raised area. Local temperature rise due to friction is thus probably a large contributing cause for bringing about the stationary hot-spot condition. When a brush is badly overloaded the hot-spot temperatures may rise to as high as 2,000 deg. cent., sufficient to graphitize the minute areas affected.

With these observations in mind it appeared that if the current passing through the hot spot could be blocked and some other portion of the brush face, or even another parallel-connected brush, could be forced to take the load for a portion of each revolution of the commutator or slip-ring, perhaps a more uniform distribution of current under the brush face and between parallel-connected brushes would result, as well as an absence of local spot heating and glowing.

Two schemes were evolved: (1) a row of side-by-side, straight-around offset grooves; and (2) the helical groove (see Fig. 1). Both schemes were tried out and gave similar results with the exception that the helical groove was easier and cheaper to make and could be cleaned more readily if necessary. In both schemes a given spot on the face of the brush can carry current and can be subjected to frictional heating for only a portion of each revolution of the slip-ring or commutator; during the remainder of the time some other spot or group of spots are forced to carry the load. Any air trapped under the brush face, sometimes a contributing factor in uneven current distribution, is permitted to escape as are any loose abrasive, solid particles of brush or ring material.

LABORATORY TESTS ON SLIP RINGS

The first tests were made to determine the effect of grooving upon contact resistance. Two copper slip-rings were used, one plain and one grooved, both mounted on the same shaft. Each was equipped with

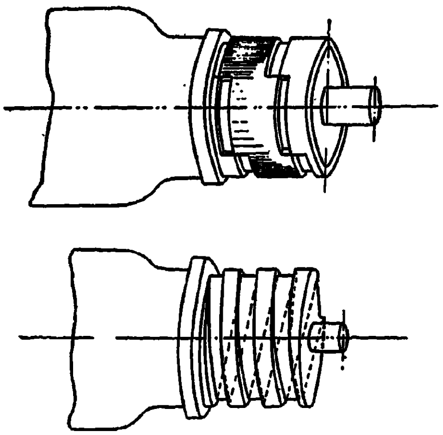

Fig. 1. The two types of grooves treated in this article. (Above) "straight around" offset groove; (below) helical groove

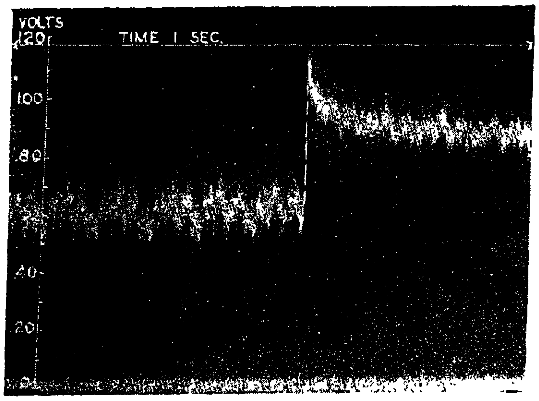

Fig. 2. Change in voltage drop on plain slip-ring as current was suddenly increased from one to seven amperes

Note the high voltage drop during the first fiftieth of a second after change. With the helical groove the current-carrying time of any given brush spot can be limited to less than 1/50 sec. thus maintaining the desirable condition of high contact drop and low operating temperature

one positive and one negative brush and the rings were so arranged that they could be operated either in series or in parallel. At the start, with clean sandpapered rings and brushes, the contact resistance on both the rings was extremely low, but the grooved ring brush-contact resistance was almost always much lower than that of the plain ring. The resistance of both rings then slowly rose until finally after from 20 to 30 hr. the resistance of the grooved ring and brushes became about 20 per cent higher than that of the plain ring and its brushes.

While the difference in the character between the slowly formed surface film of the grooved ring and that of a plain ring is probably the main reason for the difference in the contact resistance (the 20 per cent increase), there is another well demonstrated cause. An oscillogram shows that on a plain ring a sudden, forced increase in current density at the contact between a brush and a ring causes a large but rapidly diminishing increase in the contact resistance (see Fig. 2). It would appear that with a suddenly applied current an appreciable time is required for the temperature of the current-carrying contact spots to rise, during which time the resistance (owing to the negative temperature coefficient) remains comparatively high. The helical-groove scheme furnishes means of control whereby the duration of time that any given spot on a brush face could carry a heating current and maintain frictional contact was limited to 0.02 sec. or less; and from an inspection of the oscillogram as given in Fig. 2 it appears reasonable to believe that this would account for the increase in contact resistance noted.

Another test (made at the laboratory of the Stackpole Carbon Co.) on five parallel-connected metal-graphite brushes on a plain bronze slip-ring gave frequent exhibitions of one or two brushes taking all of the current; later the same brushes run on a grooved ring were free from this trouble.

Further tests were made with a grooved and a plain ring in series and with only one brush on each ring. While the set was subjected to a heavy overload it was observed that while the plain-ring brush sparked badly the grooved-ring brush operated perfectly.

Still another test was made on plain steel rings operating in an atmosphere of hydrogen. Concentration of current and local overheating caused pitting of the brush face and the formation of extremely hard particles (apparently iron carbide) which became imbedded in the face of the brush and rapidly scored the surface of the ring. Grooving this same ring did away with the scoring of the ring and the coarse pitting of the brush face.

LABORATORY TESTS ON COMMUTATORS

One of the first of these tests was made on a defective 2,000-ampere 500-volt d-c. generator. This machine would carry ½ or ¾ load very satisfactorily, but on full load, trouble would develop within a few hours' time, while on 50 per cent overload, glowing, sparking, and streamers would develop at the commutator within ten minutes.

A ⅜-in.-pitch ⅛-in.-wide groove was then cut into the commutator after which the machine carried full load indefinitely (over a week) with no glowing, and withstood the 50 per cent overload for three hours; also it was noted that the grooved commutator ran 10 deg. cent. cooler than the plain commutator. Later this same grooved commutator was operated at full load and 8 of the 44 brushes removed; no distress was observed. This suggested that with grooving, commutators could be built shorter and with less expense.

A long test (200 hr.) was then made on a 40-ampere 500-volt d-c. traction motor, with first a plain and then a grooved (⅛-in. ridge, ⅛-in. groove) commutator. A

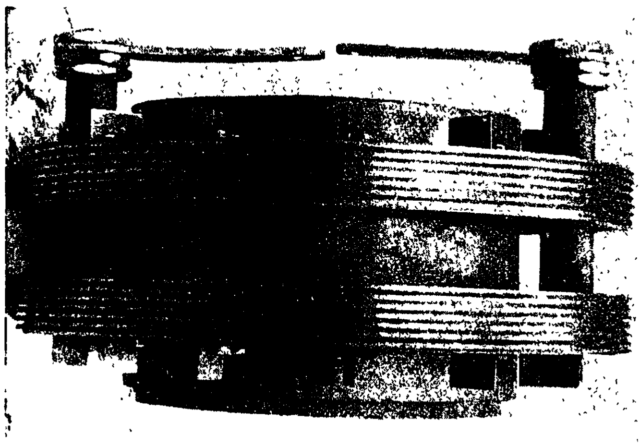

Fig. 3. Grooved slip-rings for a 15,000-kva. hydrogen-cooled synchronous condenser. The grooves are 1/8 in. wide, with a 1/8-in. ridge and a 1/2-in. pitch

reduction in sparking, a seven-degree lower operating temperature, and a more uniform current distribution between parallel brushes were noted after the commutator had been grooved; also the commutator was in better condition at the end of this test than at the end of the test made before grooving.

It appears from the above data that grooving a commutator probably does much more than simply to prevent the formation of hot spots; the cooler operation suggested that the wasteful circulating current occurring under a brush face during ordinary commutation, probably had been reduced. This can be explained only by assuming that the contact resistance had been raised. Reduction observed in the sparking at the trailing edge of brushes on a grooved commutator may be explained also by the increased contact resistance which served to cut down the volume of circulating current which the spark had to handle.

Other Considerations

The depth of groove appeared to have little or no affect upon the performance, although it is reasonable to expect that due to its increased radiating surface and the larger amount of cooling air that is dragged across the brush face a deep groove might promote cooler operation.

Width and pitch of the groove are still being studied; it would appear that to secure the best results in different kinds of service, these dimensions will vary somewhat.

When grooving a commutator it is very desirable to stone the surface after the groove has been cut in and the edges slightly rounded. Any burr left is disastrous to brush life and sandpapering alone is not effective. For subsequent polishing, a very fine sandpaper backed by a wooden block is best.

Commercial Applications to Slip-Rings

The slip-ring tests described were so convincing that when the information was divulged to one of the public service companies, this company decided to cooperate in an experiment on the rings of one of their 13,000-ampere synchronous converters. The operation proved so satisfactory that now another machine is being grooved and put into service. A second public service company is putting into operation a 15,000-kva. hydrogen-cooled synchronous condenser equipped with helically grooved steel slip-rings also running in hydrogen. (See Fig. 3).

The Calculation of Generator Heat Losses

PREDETERMINATION of the temperature in electrical machinery involves three distinct problems: (1) magnitude and distribution of the losses, (2) flow and cooling effect of the cooling medium in the machine, and (3) heat flow from source to cooling medium.

C. Richard Soderberg of the Westinghouse company in a recent A. I. E. E. paper (see foot-note) describes an unique method of calculating heat flow and heat losses within large turbine-generators under conditions of steady temperature. In his ingenious method the author utilizes "equivalent thermal circuits" for solving two-dimensional problems of heat flow.

To the third of the three problems first enumerated the author devotes his paper, which represents "an attempt at a reasonably complete solution for the heat losses in large machines with deep slots, where the temperature drops through the various iron paths are of real consequence. The analysis proceeds by progressive stages of elaboration from a simple conception of the general aspects of heat flow to what is believed to be a fairly correct picture of the complicated phenomena involved.

"Many elaborate mathemtical deductions are given . . . . Several details of the analysis have been carried to a degree of refinement which may be considered impractical for ordinary types of machines. An approximation, however, is justified only when the degree of approximation is known, and this has not always been the case with approximate methods commonly used."

From "Heat Losses in Large Turbine-Generators" (No. 31-33) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931. (For publication in the A. I. E. E. TRANSACTIONS the title of this paper has been revised to read "The Steady Flow of Heat in Large Turbine Generators.")

Synchronizing Salient-Pole Motors

By means of the integraph the differential equation of motion for a synchronous motor during pulling-into-step transients is readily solved. An expression thus can be set up to predetermine the limiting conditions under which such a motor will synchronize.

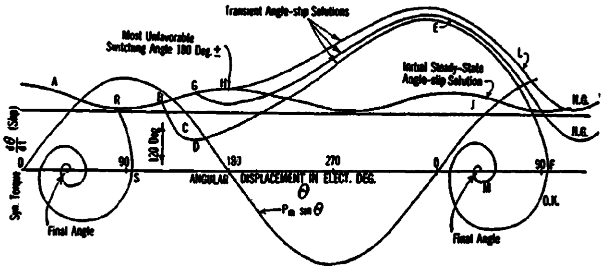
By
H. E. EDGERTON Massachusetts Institute of Technology
Associate A. I. E. E.

PAUL FOURMARIER Massachusetts Institute of Technology
Non-Member

CALCULATION of the pulling-into-step phenomena of a synchronous motor presents one of the knottiest problems in electrical engineering. After a motor is brought up by induction-motor action to as high a speed as is possible, the field is excited with direct current and the resulting synchronizing force tends to pull the motor into step. In case the moment of inertia is small and the shaft load relatively light, the motor will have no difficulty in pulling into step. When synchronous motors are used to drive loads having large torques or large moments of inertia, a condition is approached where the synchronizing force due to the d-c. field will not be of sufficient value to pull the motor into synchronism. The principal object of this investigation was to establish a criterion between the various factors that enter into the problem of the limiting case between satisfactory and unsatisfactory operation, in order that the operation of any particular motor might easily be predetermined.

A consideration of pulling-into-step problems in general for salient-pole motors shows that the following important factors influence the phenomena:

1. Load torque on the motor shaft, which in turn determines the amount of slip when running as an induction motor.
2. Maximum available synchronizing torque, which in most motors is practically proportional to the field current.
3. Inertia of the rotor and connected rotating masses.
4. Effectiveness of the amortisseur windings and field circuit as an induction-motor rotor.
5. The displacement angle between the impressed voltage and the voltage induced by the d-c. field when the exciter is connected.
6. Reluctance torque which is a function of the angular displacement.
7. The degree of unbalance in the induction-motor torque, due to the incompleteness of the amortisseur winding.



Typical integraph angle-slip solution of the equation of motion of a synchronous motor during pulling-into-step transients

All seven of these factors appear in the differential equation of torques and solutions of this equation show their influence.

Until the advent of the integraph calculation of this differential equation was possible only by difficult, approximate methods such as step-by-step analyses and energy relations. The integraph is one of the results of the efforts of V. Bush and others at the Massachusetts Institute of Technology to find mechanical and electrical methods of solving the apparently unsolvable or tediously solvable integral and differential equations which so often are encountered in engineering work.

This investigation is a continuation of a previous study of the conditions for the pulling-into-step of a wound-rotor, synchronous motor.

The details of this investigation were published in the September 1930 issue of the *Journal of the Institution of Electrical Engineers* (London), and by it a criterion for satisfactory synchronization was evolved in terms of the moment of inertia, synchronizing torque, and other factors. The continuation here considers the effects of salient poles and incomplete amortisseur windings, the solution being obtained in a similar manner by means of the integraph.

The conclusion drawn from the study is a relatively simple empirical expression which can be used to represent the pulling-into-step characteristics of salient-pole synchronous motors, this criterion being the following:

$$s < \frac{590}{n}\sqrt{\frac{P_m}{f\,(W\,R^2)}}$$

where s = initial slip as an induction motor.
n = synchronous speed in r. p. m.
f = frequency in cycles per sec.
$W R^2$ = (moment of inertia in lb.-ft.)^2
P_m = maximum synchronizing power in kw. due to the field current.

According to this criterion the amortisseur windings must raise the rotor to such a speed that the average initial slip is less than the indicated function of the speed, frequency, moment of inertia, and synchronizing power, in order that synchronism may result on the first swing for the *most unfavorable switching angle.*

From "The Pulling Into Step of a Salient-Pole Synchronous Motor," (No. 31-48) presented at the A. I. E. E. winter convention, New York, Jan. 26-80, 1981.

One of the conclusions of this study is that the reluctance torque does not influence the value of the criterion to any considerable extent. The reason for this is that the reluctance torque makes the initial slip more unfavorable than it would be if it were not present (as in wound-rotor machines) but a greater synchronizing effect is exerted by the joint action of the reluctance and synchronizing torques. These two opposite influences of the reluctance torque tend to cancel, and therefore its net effect on the ability of the motor to synchronize is inappreciable.

The degree of unbalance of the damping winding apparently also has a rather minor effect on the critical ratio. This is undoubtedly due to the fact that the rotor swings through such a large range of values of angle that only the average damping is of importance.

By means of the criterion equation, calculations of limiting slip were made for a 160-hp. synchronous motor, and according to these calculations the maximum value of slip at which the motor would pull into step was 0.0143. This represented the limiting value for the worst switching angle. In laboratory tests at these most unfavorable switching angles, the value of slip at which the motor would actually synchronize varied from about 0.014 to 0.015, which is in very close agreement with the calculated value.

A Concentrator for Printing-Telegraph Circuits

The termination in a telegraph office of a large number of "start-stop" printing telegraph circuits, requires some means for concentrating the circuits to enable incoming and outgoing traffic to be handled efficiently and economically. A multiple-turret concentrator which permits any one of many circuits to be worked by any one of a few operators is described here.

By
WILLIAM B. BLANTON The Western Union Telegraph Company
Non-Member

DURING recent years great improvement has been made in printing telegraph systems which employ the start-stop method of synchronism. Printers adapted to such systems are known by various names, some of which are start-stop printer, simplex printer, teletype, telephone typewriter, typing telegraph and teleprinter.

The telegraph companies are using in increasing numbers printers of this type on circuits which connect to the central telegraph office the public-branch offices within a city as well as the offices of those patrons who have sufficient message traffic to warrant the telegraph companies incurring the expense of providing such a connection.

The majority of such circuits is worked intermittently and therefore the continuous services of an operator are not required at the operating terminals of each circuit. In order to handle efficiently and economically the traffic on a large number of these circuits which enter a telegraph office, there is required some means for concentrating the circuits so that any one of a large group can be worked by any one of a smaller group of operators.

Before the equipment described in this paper was decided upon, three methods of concentration were considered; (1) automatic switching of calling lines to idle operators, (2) manual switching by an arrangement somewhat similar to a manually-operated telephone private-branch exchange, and (3) lines multipled before each operator.

A study of the economics and operating advantages of these three methods, and their adaptability to the present methods of handling telegraph traffic, led to the choice of the latter arrangement; in other words, a multipled-turret concentrator.

A general view of a typical concentrator installation having 50 operating positions and a capacity of 100 lines is given in Fig. 1. It is not intended that the line capacity of this type of concentrator be limited to 100 lines; in fact installations already have been made of 200 line concentrators, and it is quite practicable to accommodate more than 200 lines with the use of the same type of equipment. The number of operating positions provided depends upon the traffic load and is determined individually for each concentrator. In actual installations of 100 line concentrators the number of operating positions has varied from 20 to 70.

All of the lines to be worked in a concentrator appear in a turret (*B*) at each operating position. These turrets are simply small switchboards connected in multiple.

Associated with each line is a relay arrangement

From "A Printing Telegraph Concentrator," (N . 31-1) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

F—Message drop

which serves to light the calling lamps when the outer office initiates a call. This equipment must also function to extinguish the calling lamps when an operator answers the call and must be restored to the condition where it will be in readiness to receive another call when the operator disconnects. Generally, in multiple-turret arrangements this relay device is controlled from the operating positions over a conductor separate from the line circuit, thus necessitating that an extra conductor for each line be multipled from turret to turret. Since the cost of the turrets and the cabling required to connect them in multiple is a large item in the total cost of a multipled-turret concentrator, particularly when the ratio of turrets to lines is as high as 70 or 100 an endeavor was made to simplify the turrets and reduce the number of conductors in the multiple. To this end, the concentrator is designed so that the turret multiple comprises only one conductor for each line, the control of the relay equipment which actuates the calling lamp being accomplished over the line conductor.

The use of the one conductor multiple permitted a departure from common practise in the design of the turret. Instead of jacks, the line conductors are terminated on studs molded in bakelite panels. Fig. 2 shows a 100-line turret equipped with two of these panels; over each stud will be noted the line designation. The major advantages of these panels over an equivalent arrangement of jacks and designation strips are reduced cost of apparatus and installation, and saving of space by use of a shallower turret.

Instead of associating a calling lamp with each line stud in the turrets, the lamp cabling is greatly simplified by distributing calling-lamp cabinets containing one lamp for each line among the operating positions so that each cabinet is visible to, and used by, a number of operators.

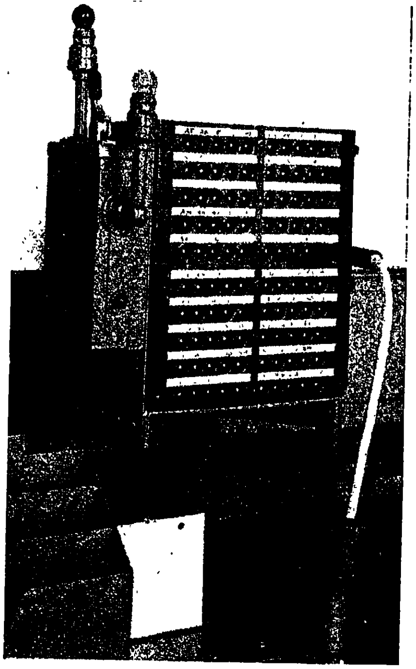

Fig. 2. Signal assembly and 100-line turret

The printer apparatus at each operating position (Fig. 3) is included in an operator's cord circuit which terminates in a jack-plug (*P*), so termed because it is used like a plug but contains springs which operate like jack springs. It is by connecting the jack-plug to a line stud in the turret that an operator connects that printer to any desired line.

When an operator at an outer office initiates a call, the calling lamps associated with this line in all of the lamp cabinets light. To avoid the confusion of all of the idle operators endeavoring to answer the call, and at the same time make sure that the call is answered promptly, the responsibility for answering is placed by virtue of an "answer-next" system upon the lowest-numbered idle operator. This system provides an answer-next lamp (*N*) on each operating position. Only one of these lamps in the entire concentrator is lighted at a time, and that lamp is always located before the lowest-numbered idle operator. This lamp glows steadily when there are no calls and flashes the instant a call appears. The operator then refers to the nearest lamp cabinet (*R*) and proceeds to attach the jack-plug to the line stud having the same relative location in that turret (*O*) as the lighted calling lamp has in the lamp cabinet. Immediately after the operator has made the connection, the answer-next lamp is extinguished and the lamp in front of the next lowest-numbered idle operator will light.

The printer (*T*) is a tape printer. During the reception of messages the operator gums the tape of each message on a telegram blank, stamps the time on the blank and then places it on a belt conveyer (*H*) which runs along the rear edge of the operating table. This conveyer feeds into a conveyer system that carries all received messages (including those received by other facilities) to the main routing center of the office.

All messages received at this main routing center and destined for an office the line of which terminates in a concentrator are dispatched by a conveyer to a message-routing rack centrally located at one end of the table rows of the concentrator as shown in Fig. 1. One or more clerks then sort these messages, according to their destination, into the proper compartment of the message-routing rack which has one compartment for each line terminating in the concentrator. Other clerks called "routing aids" immediately take these messages out of the rack and carry them to concentrator operators; messages for an office the line for which is busy are taken to the operator then working that line, while messages for an office with line idle are taken to an idle operator.

Fig. 4 shows the front view of a message-routing rack provided with 100 compartments; underneath each compartment are located five lamps utilized by the routing aids in locating the operator working any particular line. Referring to Fig. 1 it may be noted that the operating tables are divided into five distribution groups. When a line is busy, one of the five lamps associated with this line at the message-routing rack is lighted, that particular lamp denoting in which distribution group the operator then working that line is located. Thus the routing aid is guided to the proper group of tables, views the turret on each busy position, and ascertains by the location of the jack-plug which operator is working the line in question.

If none of the lamps under a particular compartment is lighted, the associated line is idle. When removing a message from such a compartment, the routing aid looks at an idle-operator indicator which is generally suspended from the ceiling and located just to the rear of the routing rack. By means of lamps this indicator shows the location of all the operators idle at that moment. As a further aid to locating the idle operators, each operating position is equipped with a green light (*M* in Fig. 3) which shows when the operator is idle.

Occasionally a message may be handed to a concentrator operator for transmission to an office which at that moment is being worked from another concentrator position. Since no busy lamps are included in the turrets, the operator is not aware of this busy condition and plugs in on the line stud. The cord circuit, however, contains an arrangement which automatically prevents the printer equipment from being connected to

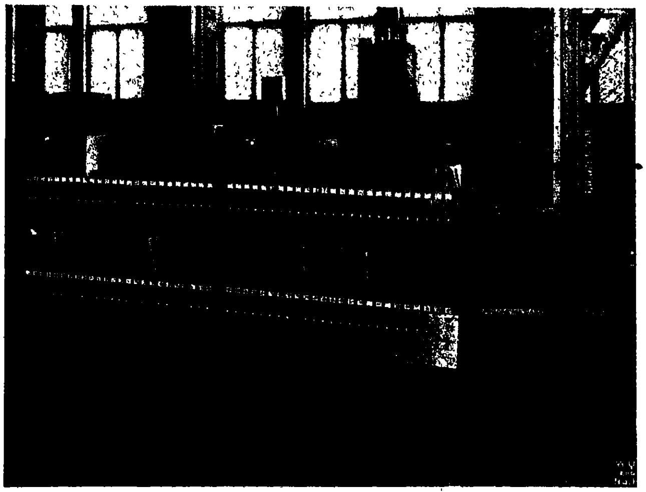

Fig. 4. Front view of message routing rack

a busy line, and furthermore, this arrangement is such that no interference is caused to printer signals which may at that moment be passing over the line circuit. The fact that the plugging in has been done on a busy line is indicated to the operator by the lighting of the busy-line lamp (*L* in Fig. 3). If the operator fails to see this signal and attempts to send on the printer, the printer due to the fact that the motor is not running will not function.

Several supervisory lamps are conspicuously located at some point about the concentrator; these lamps serve to warn the supervisor of conditions which require immediate attention, such as calls not being answered promptly or an insufficient number of operators.

All start-stop printing telegraph circuits entering the larger telegraph offices are terminated in concentrators even though some of these circuits require the individual attention of an operator during the greater part of the day.

Because the lines are of various lengths and characteristics, it is necessary to equate them for termination in a concentrator. Short lines are terminated directly in a concentrator multiple. The longer lines are terminated in single-line or duplex-half repeaters or terminal-duplex sets, the local sides of which are connected to the multiples.

Brazed Joints for Electric Conductors

Electric resistance brazing produces in electric conductors joints which possess several distinct advantages over equivalent soldered joints, and in addition can be made at a lower cost. A description of the equipment and process is given with comparative results between the two types of joints.

By
SAMUEL MARTIN, JR.
General Electric Co.
Schenectady, N. Y.

ELECTRIC RESISTANCE BRAZING has been developed to meet the need for a better means of joining two electrical conductors. Not only have brazed joints higher heat resisting qualities and higher mechanical strength than soldered joints, but they possess high electrical conductivity as well. The simplicity of the brazing process is well illustrated by the following brief description: the parts to be joined are first clamped between a pair of carbon blocks; current is then passed through these blocks and the joints, thus heating the blocks and the parts to be joined to the melting point of the brazing alloy. The alloy, which for convenience is usually in the form of a thin strip, is then applied to the contact surfaces, is melted, and flows through the joints, uniting the parts into a solid mass.

The equipment required for making this type of joint is equally simple, consisting only of an air-cooled transformer with primary and secondary leads (the latter being connected to the brazing tongs), a foot switch, and specially designed clamping tongs for holding the work. Special transformers were designed to meet the many varying factors encountered in this work. In order to heat the parts to be brazed quickly, high current is required in the secondary circuit which is subject to momentary overloads of as high as 400 per cent. With these high currents a small reactance in the leads between transformer and tongs affects the power factor materially. For any given length of lead (7-ft. being recommended), the type of carbon block, kind of joint, and amount of contact between blocks and joint also affect the power factor.

For conductors up to 300,000 cm. in cross-section, a 5-kva. transformer has been found satisfactory; for conductors from 300,000 to 2,000,000 cm. in cross-section, a 10-kva. transformer has been found a convenient size.

The complete equipment for making joints on conductors up to 2,000,000 cm. in cross-section weighs less than 100 lb.; hence it can be transported easily from place to place. For larger joints stationary machines or presses have been adopted using much larger transformers.

Proper preparation of the work for brazing is of prime importance. Parts to be brazed should be as flat as possible so that the carbon blocks will come into intimate contact with the entire surface, thus guarding against arcing and hot spots between the blocks and parts being joined. In joining round or irregularly shaped pieces the carbons may be cut to fit the piece. In general, flat plate terminals (see Fig. 2) will replace the tubular terminals commonly used in soldered joints. If the flat plate terminal

---

From "Electric Resistance Brazing," (No. 31-16), presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

or busbar is more than 1 in. wide, it is slotted and the brazing operation performed on each individual section as a separate operation.

Standard cable is usually prepared by wrapping with thin copper strip or inserting the end of the cable into a thin copper tube; then flattening before clamping in the tongs. If a very flat joint is desired the thin copper strip should be wound around the strands rather loosely. In all cases the wrapping or tubing should extend from ½ to 1 in. beyond the portion being brazed. Copper braid is prepared in a somewhat similar manner as may be noted in Fig. 2. In this case a copper clip about 0.02 in. thick and slightly wider than the braid is placed on the end of the braid, extending about ½ in. beyond the contact surface. Depending upon the size of the cable, insulation should be removed for a distance of ½ in. to 2 in. from the joint, the bare cable being wrapped with damp asbestos to protect the insulation from overheating during the brazing process. Flat joints are made by lapping the pieces to be brazed about 1½ times the thickness of the conductor. If it is desired to make a butt or scarf joint on rectangular conductors, this can be done by clamping the two ends together, then applying the carbon blocks to the edges of the conductor and feeding the alloy in from the flat side.

In soft soldering it is very essential that the surfaces be clean and free from oxides or other impurities. This is not so essential in brazing but certain oils and varnishes are not attacked by the brazing flux and should be removed. Generally fused borax is used for the flux, and it may be applied either in dry powder form from a small sifter or mixed with water or vaseline and applied to the joints in paste form. Depending upon the joint to be made, three different silver alloys are used as a brazing medium; these contain respectively 10, 20, and 50 per cent of silver. Alloys containing the higher percentages of silver have a lower melting point (about 730 deg. cent.) and are consequently used on small parts where temperatures must be kept down to a minimum. The 10 per cent silver alloy is satisfactory on larger cables, terminals, and busbars, where a higher brazing temperature (830 deg. cent.) is not objectionable.

The economics of adopting brazing in place of soldering are sound. Many cost studies have been made on various sizes of cables, plates, bars, and other conductors, and for purposes of comparison three typical cases are presented in Table I.

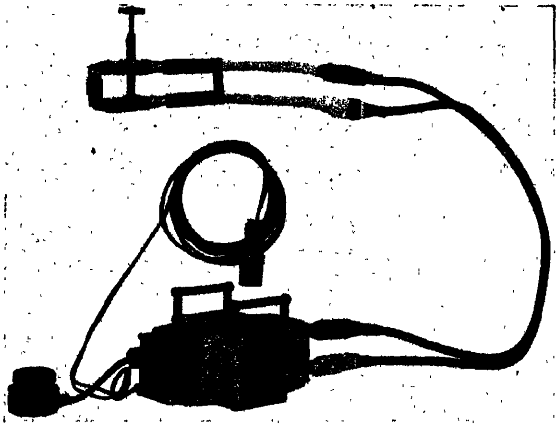

Fig. 1. Complete resistance-brazing equipment with 10-kva. transformer having 8-, 10-, and 12-v taps on its secondary winding

TABLE I—COST COMPARISON BETWEEN BRAZED AND SOLDERED JOINTS

Case	Preparation time	Brazing or soldering time	Finishing time	Cost of alloy or solder	Cost of labor at 60c./hr.	Total cost
1-B	3.41	3.17	1.2	0.027	0.077	0.104
1-S	3.41	5.17		0.025	0.085	0.110
2-B	10.90	7.28	4.0	0.225	0.220	0.445
2-S	10.99	17.97		0.247	0.288	0.535
3-B	5.35	15.57		0.225	0.209	0.434
3-S	5.35	24.80		0.46	0.302	0.762

In the column headed "Case,"
B—Brazed joint
S—Soldered joint
1—Terminal joined to 180,000-cm. cable
2—Terminal joined to 1,500,000-cm. cable
3—Twelve 1/8-in. by ¼-in. conductors are joined to a 770,000-cm. cable

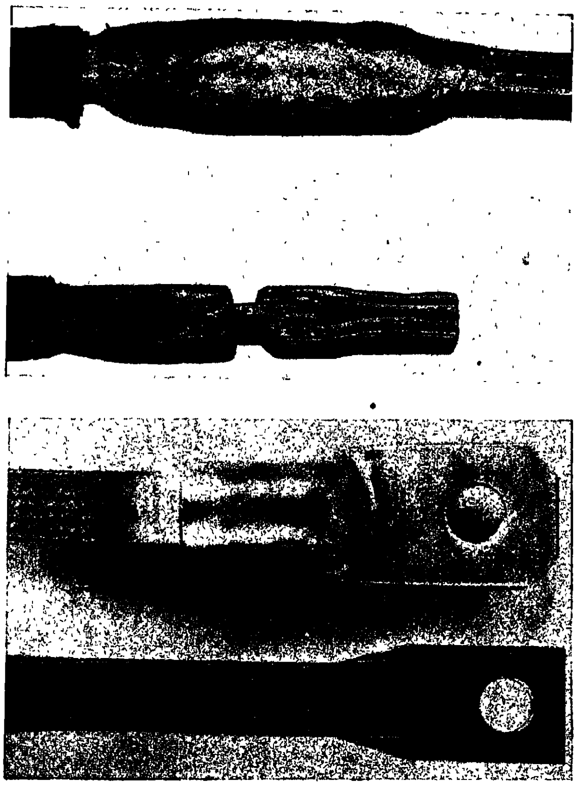

Fig. 2. A comparison between brazed and soldered joints; (above) two large conductors joined together; (below) brazed flat plate terminal and soldered tubular terminal on copper braid

In this table the preparation time includes skinning, binding, and forming the cable; finishing time is that required for cleaning. These costs have been computed for soldering under the most favorable conditions; if labor were figured at 90 cents per hour the saving on that item would be much greater.

In addition to their economic advantages brazed joints present several other distinct advantages over soldered joints. When silver solder is applied to a copper joint it dissolves a thin film of the copper surface which is very rich in copper; hence it is an excellent conductor of electricity. Since the melting point of this alloy is higher than that of the silver solder a higher temperature is always required to open the joint than to form it. If the lapped joints are designed in each case to have a contact area of at least 1½ times that of the conductor cross-section, the factor of safety is such that the joint will carry as much overload as the conductor itself. In Fig. 2 it may be seen that brazed joints besides being much more accessible for inspection are much smaller than soldered joints. These factors together with the improved mechanical strength and durability of brazed joints mark another distinct step forward in the electrical industry.

A Vacuum-Tube Voltage Regulator

A device has been developed which not only provides voltage regulation for alternators, but short-circuit protection as well. Saturation current from the filament of a thermionic tube forms the control element, while stabilization is accomplished by a feed-back system.

By

L. C. VERMAN Associate A. I. E. E. — Cornell University, Ithaca, N. Y.

L. A. RICHARDS Non-member — Cornell University, Ithaca, N. Y.

VACUUM TUBES have come into general use during the past few years for controlling and regulating various types of electrical apparatus where extremely accurate regulation of speed, voltage, or other factors, is required. These applications have been confined in general to small apparatus, but few attempts having been made to adapt such means of regulation to meet the needs of large power units.

Recently, however, a regulator of this type was developed by the physics department of Cornell University, and has been in use for about two years in the laboratory on a 25-kw., 110-volt, d-c. generator. This regulator has required no readjustments or replacement of parts.

Encouraged by this performance, a similar voltage regulator has been developed for use on alternators. Operation of this regulator involves conversion of a-c. line-voltage fluctuations into corresponding d-c. variations, amplifying these and applying them to the field of an exciter which supplies the main alternator field, thus controlling the line voltage.

A schematic diagram of the regulator circuit is shown in Fig. 1. As may be noted, the amplifying system is of the ordinary resistance-coupled type. All the grid bias and plate voltages are supplied by a single "B-eliminator" system operated from the alternator being regulated. Tube filaments are lighted directly by alternating current through individual transformers also supplied from the generator under regulation.

The first tube (in this case a UX-210 type) is operated at a low filament temperature and high plate voltage, so as to obtain saturated plate current. Under these conditions the current through the coupling resistance R_2 is nearly independent of the plate voltage but changes rapidly with the filament temperature and hence with the r. m. s. value of the line voltage. This scheme was found to be superior to a grid-control method since the grid potential must be obtained from

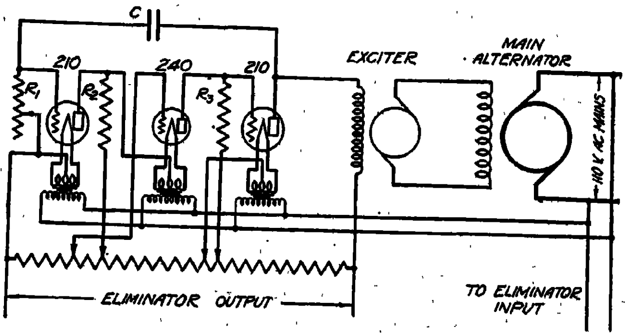

Fig. 1. Schematic diagram of regulator

From "A Vacuum-Tube Voltage Regulator for Alternators" originally submitted to the A. I. E. E. and subsequently published in full in the *Review of Scientific Instruments*, Oct. 1930.

the B-eliminator output voltage which is more closely related to the average rather than the r. m. s. value of the line voltage.

Voltage drop across R_2 is balanced out by a small adjustable portion of the eliminator output and is then applied to the grid of the second tube—a high-μ, UX-240 type. Thus a decrease in the line voltage makes the grid of the second tube more negative, cutting down the current through R_3, which makes the grid of the last tube more positive thereby building up its plate current. This increases the exciter voltage, builds up the main alternator field and boosts the line voltage. An increase in line voltage simply reverses this process.

A UX-210 type tube is employed in the last stage of the amplifier to supply the field current to the exciter generator whose field is wound to match the d-c. plate resistance of the tube. This field winding is the only special piece of apparatus used in the entire system, all the other parts being of standard make and readily obtainable.

Since the vacuum-tube system is almost instantaneous in its response to small fluctuations, the original regulator with the high amplification required for regulating a-c. machines was rather unstable in its operation. This condition, together with the comparatively long-time lags in the fields of the exciter and the main alternator, caused hunting, *i. e.*, oscillation of the line voltage about a mean value. After a good deal of experimentation it was found that the regulator could be stabilized by a feed-back coupling system composed of a condenser C and a resistance R_1, which reacts on the grid of the first tube. This virtually delays the response of the regulator, thus cutting down its tendency to over-correct.

PERFORMANCE TESTS

A number of experiments was made with this regulator connected to a 35-kva., 220-volt, two-phase alternator, operated as a single-phase machine at 110 volts —this being the rated voltage of the eliminator equipment. This constituted a severe test for the regulator, because for a given load the field-current correction necessary to maintain constant voltage is greater for low than for high voltages.

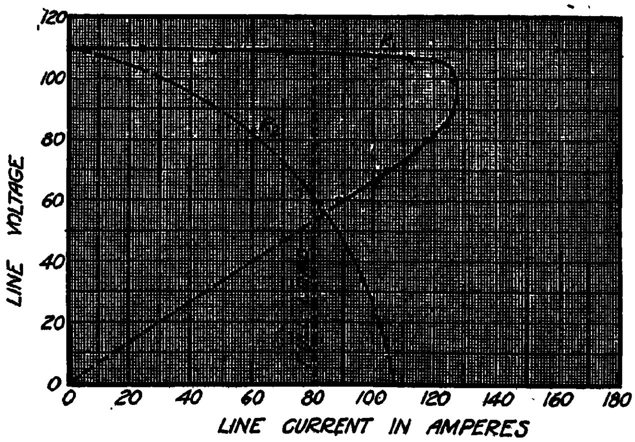

Fig. 2. Voltage characteristics of an alternator with unity-power-factor load; R_1 with vacuum-tube control; R_2, fixed excitation, without regulator

The characteristics of terminal voltage with load current at unity power factor, with and without the regulator, are given in Fig. 2. It may be noted that at full load with the regulator, the terminal voltage drops only 1.5 volts as compared with a 50-volt drop with fixed excitation.

Oscillograms (see Fig. 3) were made showing the line voltage, line current, and field current when full load at unity power factor was suddenly applied and then suddenly dropped with the regulator in operation. In these tests a regulating transformer was used to supply the B-eliminator of the regulator. This transformer was developed especially to maintain constant output voltage for a wide range of primary voltages, the load remaining constant.

With the regulating transformer in use, however, an added load of fifteen amperes at a low power factor was imposed upon the alternator and consequently the *percentage* regulation was not quite so good as when the transformer was not in use.

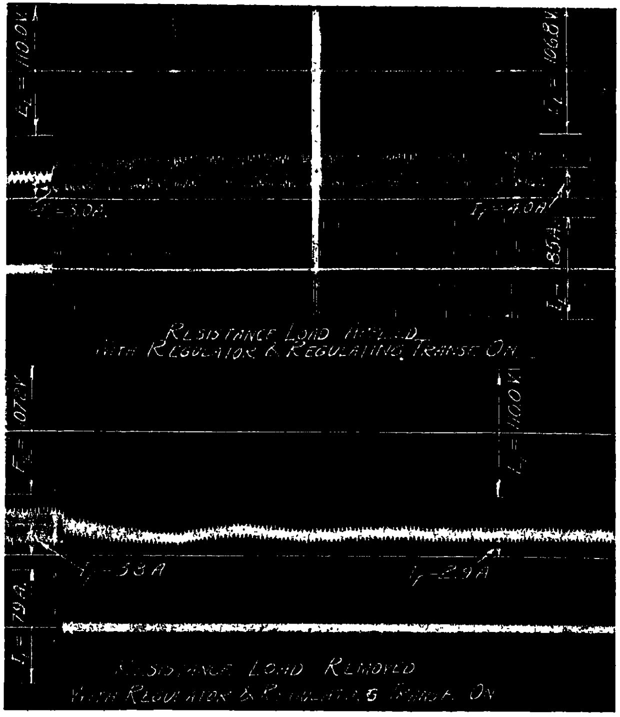

Fig. 3. Alternator terminal voltage, and field and load currents with regulator and regulating transformer in use; (above) full load is suddenly applied; (below) the load is cut off

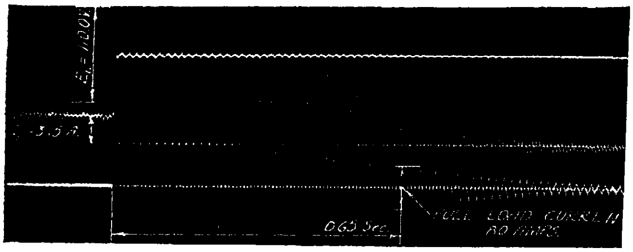

Fig. 4. Alternator voltage and current relations at time of short circuit. Note that field current is rapidly reduced to a negligible value by the protective action of the vacuum-tube regulator

PROTECTIVE ACTION

Referring again to curve R_1, Fig. 2, it may be noticed that at about 50 per cent overload the voltage starts to decrease rapidly. This is due to the fact that the B-eliminator output and the temperature of the first-stage tube filament drops sufficiently to make further regulation impossible. After the point of maximum current is reached, the system becomes unstable and the voltage drops rapidly back to zero, thus providing overload protection for the generator. The amount of overload at which the relay action starts depends upon the regulation characteristics of the eliminator as well as upon the average operating temperature of the first tube filament.

An oscillograph record showing the transient conditions occurring at short circuit with the regulator and regulating transformer in operation, is presented in Fig. 4. As may be seen, the short-circuit current is reduced to full-load value in about 0.6 sec.

FIELD CURRENT

It is shown also in Figs. 3 and 4 that the field current of the alternator is not a steady, direct current but has superimposed upon it a strong 120-cycle current. This comes from two sources: First, since the filaments of the tubes are lighted directly from the alternator, plate currents of all tubes contain a 120-cycle component which is carried right through the exciter to the main field. Second, the single-phase, 60-cycle current flowing through the windings of the armature of the main alternator induces in its field a 120-cycle e. m. f.

This 120-cycle component in the field current is of advantage, however, since the magnetic circuits of the exciter as well as the alternator are continuously carried around a hysteresis loop, thus making the average magnetic flux, and hence the generated voltage, always a single valued function of the d-c. component through the field. This field current ripple, being an even harmonic, causes no distortion in the wave form of the output voltage.

FURTHER PROBABILITIES

The regulator here described furnishes an indication of what may be accomplished by means of vacuum-tube control for power equipment. It is realized that the design might be varied to accomplish purposes other than the simple control of a single-phase machine. For example, compensation for line-voltage drop could be introduced by means of an extra winding in the filament transformer of the first tube, this winding having all or a part of the line current flowing through it. In the case of polyphase alternators a variety of schemes could be used for arranging the transformer or transformers supplying the control filament, depending upon what system voltage it is desired to control.

Motive Power for Suburban Electric Lines

Low annual car mileage together with the large number of cars required make the economical handling of suburban passenger traffic difficult. Results of a comprehensive analysis of the problem are presented.

By
CHARLES KERR, JR. Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Non-Member

MAIN-LINE RAILROADS are continually becoming more important factors in providing for the rapidly increasing suburban traffic in the larger cities. Like all urban transportation, this traffic due to the poor load factor which results from the heavy rush hour peaks, places a severe burden on the railroads. These peaks are of such magnitude that the rolling stock required to provide for this traffic is from two to six times that required for the base load. On the other hand the annual mileage of suburban cars is very low compared with that of cars in through service.

An extended suburban system embraces a variety of different types of service conditions for which the motive power must be sufficiently flexible. The average length of runs vary from a mile or less to over ten miles; the train make-up, from a few cars to many. For these

---

From "M tive Power for Suburban Electrification," (No. 31-18) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

varying conditions electrification is ideally suited, and the series motor with its steep speed-tractive effort curve meets the requirements of this service. For the short runs where high acceleration is desirable, this type of motor will deliver high tractive efforts with minimum demands on the distribution system. For the long runs where high-speed operation is desired, it will provide high balancing speeds. The steeper the speed-tractive effort curve, the better the motor is adapted to this service, a feature which makes the a-c. commutator motor well suited to suburban electrification.

The flexibility of multiple-unit cars enables trains of varying lengths to be easily formed and if desired the schedule speeds can be made independent of train size.

Modern practise in suburban electrifications employs accelerating rates not to exceed 1.0 to 1.5 mi. per hr. per sec. and maximum speeds of approximately 70 mi. per hr. Due to wheel slippage the maximum acceleration practical with two-motor equipment or four-motor equipment and a trailer is approximately 1.5 mi. per hr. per sec. The maximum speed may be raised to 90 mi. per hr. or more; but the advantage to be gained from this is small and the expense disproportionately large.

Previously it was mentioned that the annual mileage of cars in suburban service is quite low. On some systems the average is only about 25,000 mi. per car per annum, while the average for the entire country is only about 35,000 mi. Because of this low mileage, the fixed charges are the largest item of expense, and in some cases may exceed per car mile the combined cost of power, maintenance, and crew expense. With the electrical apparatus available today it is possible to reduce the operating costs greatly without materially handicapping the car performance. This may be accomplished in three ways.

LARGEST CARS MOST ECONOMICAL

The most economical car is that with the largest capacity which can be operated within the existing clearances. As the seating capacity of a car is increased, the cost, weight, and horsepower capacity per seat decrease, thereby reducing the power consumption, maintenance and fixed charges per seat. The chief objection to the large car however is its lack of flexibility. This objection is not so serious as it would seem, for most large electrifications today are faced with the problem of increased train length; with this increase the large car in spite of its lack of flexibility can be used to advantage. It is true that train make-up during the off-peak hours is slightly handicapped, but any increase in power during such times which might result from slightly heavier trains is more than counterbalanced by the reduced fixed charges. Recently there has been a decided tendency to reduce the car weight through the use of aluminum alloys, since a reduction in weight reduces the power consumption, and also the motor capacity. It is estimated that the saving of one pound reduces the operating costs per annum from 2.5 to 3.0 cents with an average car mileage of 35,000. Assuming 10 per cent fixed charges, it is economical to invest from 25 to 30 cents to save one pound in weight.

With any system of electrification in use today it is possible from a constructional standpoint to install on a car axle all the power which it is practical to utilize. This increased power may be employed either by increasing the schedule speeds or by handling trailers.

On large systems the average length of run is between 1.0 and 1.5 mi.; with acceleration of 1.0 mi. per hr. per sec. and a maximum speed of 70 mi. per hr., schedules from 20 to 40 per cent better than those with steam power can be maintained. An increase to 1.5-mi.-per-hr-per-sec. acceleration will increase the schedule speed only 3.3 per cent and will require motors 30 per cent larger. Likewise a 1.5-mi. per hr. per sec. acceleration and 90 mi. per hr. safe speed will increase the schedule speed only 6.6 per cent with a required increase in motor capacity of 67 per cent.

Because of the fact that the increase in schedule speed above a certain point is out of all proportion to the increase in motor capacity, it would appear to be highly economical to employ this increased capacity to handle trailers, thereby reducing the power consumption, maintenance, and fixed charges. During the off-peak hours sufficient motor cars will be available to provide all-motor-car operation which is desirable at these times. Power is relatively inexpensive as it does not increase the peak load demand; therefore any improvement in traffic resulting from better service is practically net profit.

As an illustration of trailer operation, a ten-car train composed of all motor cars will make only 3.3 per cent better schedule time than six motor cars and four trailers. In order to attain this 3.3 per cent increase in speed, an increase of 59 per cent in motor capacity is necessary. Costs of power, maintenance, and fixed charges are 22 per cent greater to deliver the *average* passenger at his destination less than *one minute* earlier.

To summarize, the most economical method of handling suburban traffic with electric motive power is, (1) to use the largest cars which can be operated within the existing clearances; (2) to reduce car weight, and (3) to operate all-motor-car trains or the equivalent during the off-peak hours with the extensive use of trailers during rush-hour periods.

LOCOMOTIVE OPERATION

On railroad systems operating extensive electrifications, the use of locomotive power on the heaviest trains may be desirable in suburban express service where the distance between stops ranges from three to ten miles. Due to the factor of diversity, locomotives may be operated both in through and suburban service with a large annual mileage, so that the fixed charges are low, making this operation economical. For short runs and small trains and when the annual locomotive mileage is low, multiple-unit cars offer better service at less expense.

Of Institute and Related Activities

Last Call for
The Summer Convention

ARRANGEMENTS are complete for the A. I. E. E. summer convention to be held in Asheville, N. C., June 22-26, with headquarters at the Grove Park Inn. Situated high in the southern Appalachians, Asheville offers scenic splendor of unusual interest to those who have not heretofore visited that city.

An excellent technical program has been arranged consisting of seven sessions on subjects of broad scope and current interest. Three of these sessions are symposiums; one on the important subject of power system interconnection, another on the interesting topic of communication systems for electric utilities, and the third dealing with history of electrical units, the volt, the ampere, and the ohm. Also there will be sessions on power cables, automatic stations, electrical machinery, and research.

The general convention committee has arranged an excellent series of entertainment features, sports, and inspection trips to afford visitors an attractive week of enjoyment. On Monday evening the president's reception will be held; Tuesday evening there will be a get-together dinner with entertainment; Wednesday evening the convention banquet will be given. All of these events will be held at the Grove Park Inn convention headquarters and each will be followed by dancing.

A complete list of events, tentative technical program and a description of the inspection trips was published in ELECTRICAL ENGINEERING, May, 1931, pp. 368-371. The few minor changes in program completed since the first announcement are outlined in the following paragraphs.

TECHNICAL SESSIONS

"Field Transients in Magnetic Systems" by Ernst Weber of the Polytechnic Institute of Brooklyn, N. Y., has been added to the Tuesday morning session on electrical machinery. "Residual Air and Moisture in Impregnated-Paper Insulation III" by J. B. Whitehead and F. Hamburger, Jr., of the Johns Hopkins University, Baltimore, has been transferred from the research session to the Thursday morning cables session.

GOLF—SPECIAL TOURNAMENT RULES

For golfers the main event will be the annual tournament for the Mershon Trophy, to be played over the excellent 18-hole course of the Biltmore Forest Country Club. This club is about three miles from the center of Asheville in the heart of the Biltmore Forest development. It is surrounded by beautiful homes and from almost every point there are beautiful mountain views.

It is essential that the qualifying round of the Mershon Trophy tournament be completed; this will mean that guests arriving after Monday will be unable to enter this competition.

The competition will consist of qualification round of eighteen holes, (handicap medal play) followed by match play (handicap).

The sixteen low net scores will qualify for the match play rounds, which will be played Tuesday afternoon, Wednesday afternoon, and Thursday, morning and afternoon.

Arrangements will be made by the committee for officers, section delegates, *et. al.*, to play their qualification rounds at any convenient time on Monday, so as to avoid missing their scheduled meetings.

No greens fees will be charged members or registered guests during the convention; transportation to and from all courses will be provided.

TENNIS

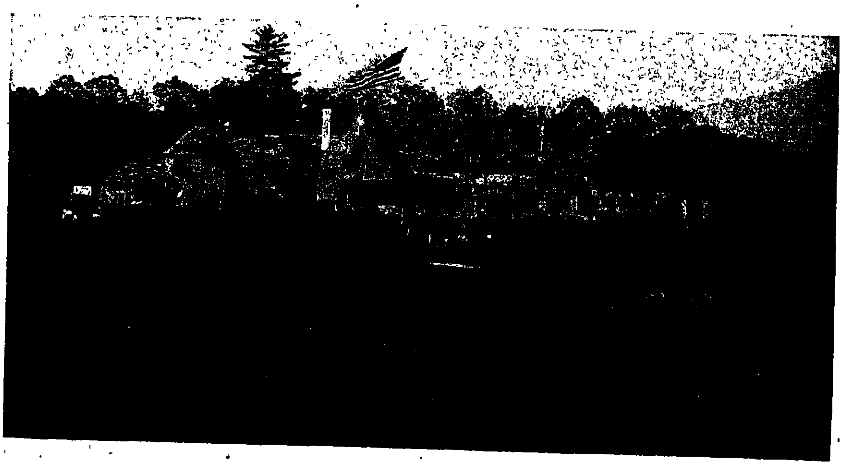
The annual Mershon Trophy competition in men's singles will be played, together with men's doubles, and if sufficient entries can be secured, ladies' singles and mixed doubles also.

The courts on which these games will be played will be announced later, but tennis players can be assured that excellent courts (probably clay) will be available for all who wish to use them.

Entries for all these events should be in the hands of the committee not later than Monday afternoon, June 22.

INSPECTION TRIPS

One of the three optional all-day trips scheduled for Friday, June 26, will be to the recently completed 25-acre plant of the American Enka Corporation the only Rayon plant in North Carolina. Inspection will be confined to the 4,400-kw. power plant and village only; the production units will not be open for inspection. The mill capacity is about 20,000



Biltmore Forest Country Club, Asheville, N. C., scene of the Mershon Trophy tournament June 22 and 24 lb. (75,000 miles) of viscose yarn per day.

Enka is about eight miles southwest of Asheville and, surrounded by the majestic mountains forming the southern extremity of the Appalachian range, is considered one of the beauty spots of western North Carolina. A water storage and settling basin has been constructed in the form of a picturesque 6,875-acre-ft. artificial lake on the borders of which three modern villages have been created for plant employees.

Invitations have been cordially extended by the State of South Carolina, the City of Columbia, and the Lexington Water Power Company to visit that state, its capital, and the 200,000-hp. Saluda River development near Columbia. The power company has offered to arrange for transportation from the railroad station to and from the dam where a barbecue will be given. Negotiations are pending with railway officials to run a special train from Asheville to Columbia at a reduced rate of fare.

If enough persons attending the convention evidence sufficient interest in this trip, arrangements will be completed for an all-day excursion Saturday, June 27.

North Eastern District Holds Busy Sessions at Rochester

BRINGING to a close for the current fiscal year the Institute's district meeting activities, engineers of the North Eastern District convened at the Sagamore Hotel in Rochester, N. Y., April 29-May 2. In addition to four regular technical sessions and a student convention there were held several special group meetings including a joint dinner meeting of national noise-study committees representing the National Electric Light Association, the National Electrical Manufacturers Association, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and other organizations.

Particularly noteworthy were the many entertainment features and inspection trips arranged by the local committees. Inspection trips included visits to the plants of such widely known organizations as the Eastman Kodak Company, Stromberg-Carlson Telephone Manufacturing Company, Bausch & Lomb Optical Company, General Railway Signal Company, in addition to stations of the Rochester Gas & Electric Company. The more diversive trips included drives through the city and a trip to Niagara Falls. A delightful series of special affairs kept women guests pleasurably active and should prove a future incentive for increasing feminine attendance at these meetings. Even the needs of golf and tennis enthusiasts were ably met.

Special credit is due to everyone assisting in the supply, installation, and operation of the public address system which was a most important contribution to the success of the technical sessions. Poor audibility in meeting rooms has killed the effectiveness of more than one otherwise good meeting. The ordinary installation of stationary microphones has failed to solve the difficulties which arise with a peripatetic speaker who spends a goodly portion of his time addressing the blackboard with his back toward his auditors. At Rochester the whole problem was admirably met with the newest thing in microphones, small units attached directly to the lapel of the speaker's coat thus removing the possibility of his walking away from the "mike." The Bell Telephone Laboratories, Inc., and the Stromberg-Carlson Telephone Manufacturing Company in collaboration installed and operated the equipment.

Two of the technical sessions were devoted to miscellaneous subjects ranging from insulation research to induction-motor design. One session was given over to an exceptionally well organized symposium on the subject of noise, covering its origin, measurement, and control. Several interesting and timely subjects crowded the student session, while the closing session dwelt upon the much-investigated but always popular subject of lightning and its related problems. Some of the "high spots" of the various papers are touched upon in the paragraphs which follow.

Power Cables and Dielectrics

In presenting his paper "Temperatures in Electric Power Cables Under Variable Loading," E. A. Church (A'29), Edison Electric Illuminating Company, Boston, emphasized the need of a practical and reasonably accurate method for making these calculations to improve cable operating efficiency. He gave a solution of the problem of determining the temperature rise from sheath surface to conductor, making use of Bessel functions and resolving the heat-flow cycle into its harmonics for separate solution as well as subsequent recombination in the proper phase relation to obtain the temperature cycle. The author stated that computations based upon his theory demonstrated that the temperature curve for any cable and load cycle may readily be calculated without excessive labor and with accuracies well within the necessities of cable constants.

Theories and calculations pertaining to the "Proximity Effect in Cable Sheaths" were presented by Prof. H. B. Dwight (F'26), Massachusetts Institute of Technology, Cambridge. He described proximity effect as being the unequal distribution of alternating current over the cross-section of a conductor as caused by current in another (parallel) conductor and stated that in some cases its calculation was of importance to prove its negligibility and in other cases to prove the importance of its consideration in connection with conductor design.

Assuming cable insulation to be essentially an imperfect condenser, Prof. C. L. Dawes (M'15) and W. M. Goodhue, both of Massachusetts Institute of Technology, Cambridge, presented a discussion of "Equivalent Circuits of Imperfect Condensers" as an aid to insulation studies and calculations.

"The Theory of Thermal Breakdown of Solid Dielectrics" as described by P. H. Moon (M'29), Massachusetts Institute of Technology, Cambridge, constituted a correlation of much of the work already done on the subject of thermal breakdown. It was the author's stated aim to present this information in a form in which it could be used by the electrical engineer for the calculation of breakdown voltage. He emphasized the fact that thermal effects are but one of several mechanisms of breakdown, and that in calculating breakdown voltage, due regard must be given to this fact.

Motors and Transformers

Some of the reasons why induction motors fail to develop their expected smooth speed-torque curves were described at length by P. H. Trickey (M'30), Westinghouse Electric & Manufacturing Company, East Springfield, Mass. He stated that present knowledge attributes the undesirable "hooks" or "cusps" in the speed-torque curves to three causes at least: (1) harmonics in the field, (2) synchronous lock-in of stator and rotor harmonics, and 3) the effect of stator slots. The first of these occupied the author's attention and it was his conclusion that harmonics in the field form have a definite effect upon the speed-torque curve; also that the assumption of each harmonic acting separately is useful (though approximate) in determining the speeds at which the worst cusps will occur.

In considering the determination of "Losses in Transformers for use with Mercury-Arc Rectifiers," E. V. DeBlieux (A'30), General Electric Company, Pittsfield, Mass., reviewed theoretical calculations previously published and discussed the assumptions involved. Methods proposed for an A. I. E. E. Standard also were described and a mathematical basis for them offered. Effort is being put forth to achieve a satisfactory method for determining rectifier transformer losses independent of rectifier losses.

"The Three-Circuit Transformer" was treated at length by C. F. Estwick (M'25), General Railway Signal Company, Rochester, N. Y. That class of transformer was described as being divided into two distinct types depending upon the relative directions of the fluxes in the mutual paths of the magnetic circuit. A typical problem for each case was cited and a mathematical analysis given.

Core-Loss Measurement

A method and apparatus for determining the core losses in magnetic sheet steels at high-flux densities were described by B. M. Smith (A'30) and C. Concordia (A'31), General Electric Company, Schenectady, N. Y. Modern demands require machines and equipment to be designed within narrowing limits and this necessitates more attention to the accurate determination of the characteristics of materials. The authors presented data in support of their contention that now it is possible to measure core losses for densities up to $B = 20{,}000$ conveniently and accurately, and that in order to obtain a true measure of "B max." it is not necessary to maintain a sine wave of induction.

Symposium on Noise

All seven of the papers presented at the noise session were liberally abstracted in the May 1931 issue of Electrical Engineering (pp. 340-354); hence they will be given no further attention here.

Student Session

President Lee (F'13) was introduced by Professor C. W. Henderson (A'20), chairman of the district committee on student activities, and emphasized very forcefully the benefits received by students who attend and participate in such meetings, stating that otherwise the contacts thus made with men and the electrical industry might not be made for months or years. He urged the young men to learn to speak and write clearly and concisely, as the presentation of reports would constitute a very important part of their engineering work.

Technical papers presented by students are outlined in the following paragraphs:

"The Theory of the Capacitance Potentiometer" as presented by A. W. Moon and W. E. Brainard, Cornell University, Ithaca, N. Y., deduced relations for the characteristics of a transformer circuit which would be suitable for use for connection across a portion of a string of high-voltage insulators. Such a connection is used now for certain instrument circuits where the cost of high-voltage instrument transformers is unwarranted; it was suggested for other possible light-load uses including radio beacons.

As a result of "Tests on 14-Megacycle Antenna Systems" reported upon by C. B. Evans, University of New Hampshire, Durham, the author stated that from experiment it appears that the most suitable radiator for 14-megacycle general amateur radio communication is a horizontal half-wavelength Hertz antenna placed as high as possible and fed as easily and as efficiently as possible. His results showed also that although antenna operation on the second harmonic is satisfactory, operation on the fundamental frequency is better.

In describing methods of "Revision of Distribution Transformer Networks," L.O. Spencer, University of Maine, Bangor, emphasized the economic desirability of building up a system of distribution maps and records, and equipment records, particularly on the older systems and where small communities and rural areas predominate. He based his comments upon experience with a northeastern electric service company whose lines and services were severely damaged by an unusually severe sleet storm in 1929, the replacement and reconstruction of these lines being rendered extremely difficult by a lack of adequate line and equipment records.

In a "Study of the Torque-Time and Slip-Time Relation of an Induction-Motor Flywheel Set Operating on a Mine Hoist," D. C. Robinson and R. W. Stone, Syracuse (N. Y.) University, attempted to solve some of the problems of industrial-motor applications where energy demands vary over a wide range within one cycle of operation. The authors presented fairly extensive experimental results together with mathematical and graphical analyses.

Possibilities surrounding "The Piezoelectric Oscillator in the Power Industry" were described by B. H. Buckingham, Massachusetts Institute of Technology, Cambridge. Super-synchronous operation of widely separated power systems through Piezo oscillator frequency control was suggested as a possibility at sometime in the future, assuming that the crystalline structure already successfully applied to the synchronization of two or more radio broadcast stations could be developed to meet the relatively rigorous demands of power-system regulation.

"A Modern Short-Wave Amateur Transmitter," recently built by the Yale Radio Club, was described by Donald Bergener of Yale University, New Haven, Conn. The set was designed and built with particular attention to high-efficiency and stable-frequency operations in the three amateur channels, 3,500-4,000 kc., 7,000-7,300 kc., and 14,000-14,400 kc. The circuit used is the tuned-plate untuned-grid type, with a power amplifier of the class-C type, using two of the '52-type tubes. A power supply common to both oscillator and amplifier is fed from a three-phase bank of 220/2,000-volt transformers through a mercury-vapor rectifier and "brute-force" filter. In operation both the amplifier and oscillator are keyed simultaneously by changing the grid bias, thus effectively eliminating noticeable key clicks. Highly successful intercontinental communication with the set was reported.

In their "Study of the Fynn-Weichsel Motor," G. S. Brown and J. C. Gibson, Massachusetts Institute of Technology, Cambridge, presented an analytical description of that motor and its operating characteristics in the direction of power-factor correction. The authors stated that in their opinion the power-factor corrective ability of the motor is in certain cases a valuable asset, but recommended careful consideration of the local conditions in connection with each individual projected application.

Under the title "Starting Windings" P. H. Trickey, University of Maine, Bangor, presented a short-cut method of designing the auxiliary starting windings of split-phase induction motors. He based his findings and mathematical analyses upon practical design experience.

Session on Lightning

Seven papers presented by thirteen authors dealing with various phases of the lightning problems were given at the lightning session. These papers in general fell into three classifications: (1) theory, evolution, and laboratory development; (2) studies of the effects of natural lightning on operating systems; and (3) studies based upon the imposition of artificial lightning surges upon operating systems. The paper "Characteristics of Lightning . . ." presented by F. W. Peek, Jr. (F'25), General Electric Company, Pittsfield, Mass., was devoted to showing how the various characteristics of lightning may be obtained from measurements on operating lines and how such results may be applied advantageously in developing line designs. The author stressed particularly the fact that oscillograms of traveling waves give a "remarkably complete and easily read story of the life and characteristics of the lightning which produces them." From these observed data the author described methods of determining cloud height, time of discharge, induced voltages, and current.

In discussing "Lightning Discharges and Line Protective Measures," C. L. Fortescue (A'23), Westinghouse Elec. & Mfg. Company, East Pittsburgh, Pa., and R. N. Conwell (A'15), Public Service Electric & Gas Company, Newark, N. J., described the mechanics of the development of a lightning stroke in a cloud and the formation of a surge on a line. Analyses of typical high-voltage line construction were presented to show the lightning performance obtained, and 220-kv. operating experience records were offered to substantiate the belief that induced surges are of relatively small importance; also that the direct stroke is the criterion for good design.

"Experimental Studies in the Propagation of Lightning Surges on Transmission Lines," were described by O. Brune and J. R. Eaton (A'27), Consumers Power Company, West Jackson, Mich. The authors presented reproductions of cathode-ray oscillograms to show the attenuation and distortion of artificial lightning surges on a power transmission line, the voltages induced by such surges in parallel wires, and the effect on tower-footing impedance of ground wires or counterpoises.

Lightning Experiences

Four of the papers presented were based upon data obtained from operating systems under natural lightning conditions.

Edgar Bell (A'29) and A. L. Price (A'30), Pennsylvania Power & Light Company, Hazelton, Pa., described the results obtained from the continuation of their "Lightning Investigation on the 220-Kv. System of the Pennsylvania Power & Light Company (1930)." Lightning instruments in service on this system include some 300 lightning-stroke recorders, more than a thousand surge indicators, 39 surge-voltage recorders, two cathode-ray oscillographs, three field-intensity recorders, four lightning-severity meters, in addition to magnetic oscillographs and high-speed recording ammeters at terminal stations. These authors are convinced that at least a large proportion of the lightning kick-outs on their 220-kv. system are caused by direct strokes to line structures or conductors.

Philip Sporn (F'30), American Gas & Electric Company, New York, and W. L. Lloyd, Jr. (M'27), General Electric Company, Pittsfield, Mass., presented data from the "1930 Lightning Investigations on the Transmission System of the American Gas & Electric Company." These authors reported that of 107 surges recorded on the system in Ohio, 33 per cent were caused by lightning, and 60 per cent by switching. Of the surges caused by lightning 85 per cent were positive or predominantly positive, and 8.5 per cent were purely negative (a ratio of ten-to-one). Of the surges caused by lightning, half were oscillatory and half were not. Of the oscillatory group, half were positive and half were negative.

W. W. Lewis (M'13) and C. M. Foust (A'22), General Electric Company, Schenectady, in "Lightning Investigation on Transmission Lines—II," reviewed the results of a five-year investigation of the effect of lightning on transmission systems. The authors concluded that direct strokes play a prominent part in causing flashovers, but admitted that induced strokes also seem important. These authors contended that conventional overhead ground wires with low tower-footing resistance take care of direct strokes as well as induced strokes, and operate to prevent flashovers. They also reflected and emphasized the opinion that the mechanism of a lightning stroke as yet is not understood, but that polarity effects are indicated to be of a highly important nature and worthy of careful consideration in line design.

I. W. Gross (A'12), American Gas & Electric Company, New York, and J. H. Cox (A'25), Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa., described the "Lightning Investigation on the Appalachian Electric Power Company's Transmission System." One of the characteristics of the system in question is the fact that tower-footing resistances almost universally are high, 250-ohms or more in many cases. Special equipment installed on that system at the present time includes 21 klydonographs, one cathode-ray oscillograph, and 35 direct-stroke recorders.

Inter-Society Cooperation Urged to Expedite Noise-Study Agreement

THAT the Institute should officially recognize the importance of the several angles of the noise-study situation by appointing qualified representatives to cooperate actively with corresponding groups in other societies was the concensus of opinion of the Institute members in attendance at a joint dinner meeting held at Rochester, N. Y., May 1, 1931. The dinner meeting presided over by P. L. Alger (F '30) chairman of the A. I. E. E. committee on electrical machinery and an aggressive leader in noise-study activities, closed a day devoted to the presentation and discussion of seven papers and the demonstration of four different types of noise-measuring instruments. Specialists and various committee members contributed to the dinner discussion which was centered upon an attempt at selection of definite units and methods of measurement and evaluation of noise. Without a common language for these essentials no cooperative progress can be made.

These topics have been under consideration for some time by committees of the N. E. M. A., A. S. M. E., and the Acoustical Society of America, and representatives of all these groups participated in the discussion. While no definite agreement could be reached, three principal questions were crystallized, the answers to which form a fairly complete basis for a system of noise measurement:

1. How shall the unit of noise measurement be defined?
2. What is a suitable scale of values for noise that will cover the wide range of noise intensities met with in practise?
3. What weighting factors shall be used to correlate the noises produced by sounds of different frequencies?

The accompanying table listing the characteristics of eight different proposed noise measurement systems indicates the ways in which these questions have been answered by different investigators. The conclusions of the Rochester meeting are summarized in the following paragraphs by Mr. Alger.

I—The Unit of Noise Measurement

Since all noise is the result of waves of sound pressure, it is logical to measure it in terms of dynes per square centimeter pressure to which the name "equivalent bars" might be given. Such a measurement being based wholly upon mechanical pressure will avoid many of the difficulties involved in a measure primarily based upon psychological effects which would necessarily change as more data are obtained. However, as tones of different frequencies are not equally audible, it is desirable to convert all measurements into equivalent sound pressure at a definite standard frequency. On this basis, the consensus of opinion was that:

Noise should be measured in equivalent bars of the sound pressure produced by a pure tone of frequency 1,000 cycles per second.

VARIOUS NOISE SCALES PUBLISHED OR PROPOSED UP TO APRIL, 1931

Name	1 Pressure dynes cm.^{2}	2 Intensity	3 Sensation level loudness	4 Noise level	5 Sound level	6	7 Masking	8 Deafening
Scale........	Linear....	Db.	Db........	Db.......	Db.	Db.	Db....	Arbitrary
Ref. pt., dynes cm.^{2}	0	6.5	Thshld.	Thshld.	0.001	0.01	Thshld.	Thshld.
Frequency		1,000	700	Street noise	1,000	1,000	Warble	Buzz
Weighted	No	Yes	Yes	Yes	Yes	Yes	Uses ear	Uses ear
			Examples					
Just painful	2,500	50	130	130	125	105	115	100
Just audibl	0.0005	−80	0	0	−5	−25	0	0
Average residence	0.05	−45	32	35	30	10	20	20

Db. = decibel. Thshld = threshold. One decibel = 12 per cent change in sound pressure.

II—THE SCALE OF NOISE MEASUREMENT VALUES

As the range of audible sound pressure varies from 0.0005 to 2,500 equivalent bars a definition of noise in terms of pressure alone does not give a satisfactory impression of its magnitude. The logarithm of the sound pressure corresponds roughly to the sensation experienced, and this quantity is also very convenient for describing the sound transmission qualities of materials. For these reasons it was the consensus of opinion that:

> While noise may properly be expressed in equivalent bars (or milli-bars or kilo-bars), it is also desirable to express it on a logarithmic scale or in decibels where the difference in decibels between two pressures P_1 and P_0 is given by 20 log P_1/P_0. The zero of the decibel scale (P_0) should be taken at a convenient reference point such as 0.001 or 0.01 bars at 1,000 cycles. That is, one decibel is defined as a change in equivalent sound pressure of 12 per cent.

There was some feeling that the reference level should be taken as the threshold of audibility but the uncertainty of this level and the probability that it will change in future as more precise knowledge is gained led the majority to prefer the absolute level mentioned above.

III—FREQUENCY-WEIGHTING FACTORS

Since the audibility of sounds of different frequencies varies from zero for frequencies below about 20 cycles per sec. through a maximum at about 2,000 and down again to zero at about 20,000 cycles per sec., it is necessary to multiply the actual sound pressures by weighting factors to reduce them to a common basis. Also, since the relative audibilities of different sound frequencies vary greatly with the noise intensity, it is necessary to use different weighting factors for different levels of noise. It does not seem practical at present to have a uniformly varying weighting factor scale incorporated in a noise-measuring device, so that it seems best to establish several different weighting-factor curves for use in different zones of noise. It was the consensus of opinion, therefore, that:

> Approximately three distinct frequency-weighting-factor curves should be agreed upon, on the basis of average experimental results with a series of observers, for use in noise zones of approximately 0-20, 20-50, and above 50 db.

All noise measuring instruments should then be equipped with three networks, giving these multiplying factors for different frequencies, and all measured results should be accompanied by a statement of the network used.

IV—ADDITIONAL QUESTIONS

Questions requiring further discussion, although their solutions do not seem necessary for immediate progress, are:

4. How shall allowance be made for the fact that all noise-measuring instruments so far known record the r. m. s. value of the weighted sound pressures, whereas the ear gives more weight to the notes of higher intensity, and to certain disagreeable combinations of them?

5. How shall allowance be made in commercial measurements for reflections from walls and other objects near the source of sound?

6. How shall allowance be made for the fact that low-frequency noises are more easily transmitted through structures than high-frequency noises, so that the relative sound pressures of different frequencies vary with the distance from the source?

7. How shall the commercially acceptable noise levels for different types of apparatus and different locations be defined?

It is believed that agreement on the three principal questions can be reached in a reasonable period through joint action of the committees of the several interested engineering societies. The Bureau of Standards and other laboratories have agreed to accept any conclusions reached by these engineering committees; hence responsibility rests upon the engineering societies for bringing this matter to conclusion.

District Executive Committee Meets at Rochester, N. Y.

The executive committee of District No. 1 held a luncheon meeting on Thursday, April 30, during the District meeting in Rochester. In the absence of Vice-President I. E. Moultrop (F '29), Wellen H. Colburn (M '26) served as temporary chairman.

A. C. Stevens (M '26), secretary-treasurer of the District, presented a detailed statement of receipts and expenditures since the October meeting of the committee, and H. J. Klumb (A '16), chairman of the local executive committee for the Rochester meeting, supplied information regarding some of the expenses incurred in that connection.

It was announced that the board of directors had approved the holding of a District meeting in Providence early in May of 1932, and, after a discussion regarding the most desirable time, the dates of May 4-7 were chosen to be recommended to the executive committee for 1931-32.

Student Activities Conference Held at Rochester

The North Eastern District's annual conference on student activities was held as a luncheon meeting on Friday, May 1, with Prof. C. W. Henderson (A '20), counselor Syracuse University Branch and chairman of the District committee on student activities, presiding. Nine of the thirteen Branches in the District were represented by their counselors and chairmen; one was represented by the counselor only. Prof. Henderson was re-elected chairman of the District committee on student activities; Prof. C. L. Dawes (M '15), counselor of Harvard University Branch, and Prof. W. B. Hall, (M '28), counselor of Yale University Branch, were elected to serve with him on the executive committee of the District committee.

Professor F. M. Sebast, (M '27), counselor of the Rensselaer Polytechnic Institute Branch, and past-chairman of the District committee on student activities, presented a comprehensive report upon the types of technical papers presented in the past by students in the District, and discussed some of the factors involved in efforts to encourage all Branches to submit papers for the annual meeting.

Henry H. Henline (M '26), assistant national secretary, gave a brief summary of the types of student papers presented in such sessions in other Districts, and the subjects discussed at their conferences.

In the discussion that followed, the principal topics mentioned were (1) the desirability of active student participation in the Branches, (2) importance of interesting sophomores and juniors, (3) contacts with Sections, (4) methods of getting more of the practising engineers to attend student sessions, and (5) the importance of visits to the Branches by national officers.

Prof. W. H. Timbie (F '24), counselor of the Massachusetts Institute of Technology Branch, and chairman of the A.I.E.E. committee on student Branches, spoke briefly of the great need among high school students for accurate information on electrical engineering, and mentioned the plans of his committee to supply it.

President Lee spoke briefly upon the importance of the student activities, and mentioned the provision for allowing traveling expenses to the vice-presidents for visits to the Branches in their districts.

A Summary of Some Rochester Discussions

ONLY discussion given at the meeting and submitted in writing in accordance with governing A. I. E. E. rules is summarized; complete discussion, together with all papers so approved, will be published in the TRANSACTIONS. The titles of the papers and the names of their respective authors were published in ELECTRICAL ENGINEERING, April 1931, page 302.

ELECTRIC POWER CABLES

F. L. Buller's discussion of "Temperatures in Electric Power Cables Under Variable Loading" was read by P. L. Alger. It called attention to the statement on page six of the paper where the heat storage capacity of the lead sheath was neglected. He pointed out that in large cables the thermal capacity of the sheath was often equal to 80 per cent of that of the conductor and 25 per cent of that of the cable as a whole and for other types of cable it might even be of a larger percentage. He suggested that the equations in the paper should be analyzed to determine the effect of the omission of this factor on the results.

R. W. Atkinson discussed "Proximity Effect in Cable Sheaths" particularly formula (7) of the paper which related to sheath losses in three-conductor cables. He analyzed this formula transforming it into a convenient form of application and presented an approximate sheath-loss formula for three-conductor cables which gave values for sheath loss but from 2 per cent to 5 per cent higher than that obtained from formula (7) in the paper.

MOTORS—TRANSFORMERS

C. G. Veinott discussed "Cusps in the Speed-Torque Curves of Induction Motors." He believed that quantitatively it would be more accurate to assume the harmonic motors excited by constant primary current rather than by constant primary voltage.

G. Camilli discussed "Core Loss Measurements at High-Flux Densities" and believed it would have been of great value had data been given to show just what errors would have occurred had the older methods of measurement been used.

MAGNETIC NOISE IN SYNCHRONOUS MACHINES

H. D. Taylor discussed this subject and explained that the theory described by the authors which accounted for tooth-frequency noise was very similar to one developed by his associates and confirmed by several years' experience in designing and testing low-speed synchronous machines. Mr. Taylor's experience also confirmed the authors' statement that the worst cases of noise are likely to be associated with pole-and-slot combinations giving nearly an integral number of slots per pole. His experience with respect to the frequency of noise differed from the authors' rule. Analysis indicated that it should be a multiple of twice the line-voltage frequency times the integer nearest to the number of slots per pole.

C. E. Kilbourne discussed this subject also and explained that from a number of observations on machines having several types of rotors he had never found a case where noise could be directly traced to the rotor. Stethoscopic analysis of the stator itself indicated an increase in the volume of noise from that stator core. Another valuable part of his discussion analyzed the general equation of A. L. Ruiz for the vibration of a homogeneous ring which when there are a large number of nodes with an increased frequency is more accurate of application to this problem than is Timoshenko's equation.

MACHINERY NOISE IN BUILDINGS

J. A. Jackson discussed this subject and explained that a much closer cooperation between the electrical industry, the architects, and the consulting engineers would be needed to solve completely the noise troubles which arise in buildings. With a tendency to reduce building cost resulting in a lighter type of construction, this problem within the past few years has become increasingly difficult. Thinner walls, floors and ceilings vibrate more readily and act as sounding boards.

LIGHTNING

F. E. Andrews discussed this subject and gave data obtained by the performance of 132-kv. lines which substantiated the value of ground wires for preventing

Floodlighting at Sea

TOWERING 128 ft. above the water line, the floodlighted funnels of the new 758-ft., 42,500-ton Canadian Pacific liner "Empress of Britain" are expected to be visible for 30 miles.

interruptions. Lines of double-circuit steel-tower construction with only a single ground wire over single-circuit portions of these lines had on the average 3.78 interruptions per 100 mi. per year while parts of these lines which had double circuits with a ground wire above each circuit had only an average of 1.10 interruptions per 100 circuit miles per year.

L. V. Bewley discussed Mr. Peek's paper "Lightning" and explained that by tying down into a single set of curves (Fig. 6) the seven main factors which characterize the magnitude and shape of induced-voltage waves due to a lightning discharge; it constituted an outstanding contribution to the present knowledge of magnitudes of induced strokes. By mathematical demonstration he illustrated the application of these equations in the Appendix of Mr. Peek's paper to a specific case.

LIGHTNING VS. LINE PROTECTION

K. B. McEachron discussed "Lightning Discharges and Line Protective Measures" and in connection with the authors' versions of the mechanism of lightning strokes he believed it would be helpful if the authors could give a more detailed explanation of just what they believed happened during the interval just before and after lightning strikes. Another point in his discussion referred to the separations between line and ground wires as shown in Figs. 3 and 4 of the paper; these he believed were unnecessarily large since many lines similar to that shown in Fig. 4 but with much smaller clearances between line and ground wires and low tower-footing resistance have had excellent operating records.

J. J. Torok's discussion of "Lightning Discharges and Line Protective Measures" was read by J. H. Cox. To supplement the general treatise of the paper the results of calculations of the effects of the tower on the reflections of traveling waves were illustrated with lantern slides. Mr. Torok also explained that the analysis and accompanying curves as presented in the paper were of considerable importance as they give for the first time a clear insight into the happenings on a transmission line at the time it is struck.

EXPERIMENTAL LIGHTNING STUDIES

L. V. Bewley discussed "Experimental Studies in the Propagation of Lightning Surges on Transmission Lines" with particular references to the authors' conclusions about the counterpoise. He presented data from tests and equations which substantiated his belief that the major benefit to be derived from the use of a counterpoise was a reduction in true grounding resistance, and that the surge impedance and reflections are quite subsidiary effects. These results indicate that a given length of wire is most efficiently employed as a counterpoise by using it as a number of short lengths in parallel radiating out from the tower rather than as a single length. The direction of the counterpoise it was thought has no particular virtue.

J. H. Cox discussed "Lightning Investigations on Transmission Lines—II." He believed that these data were gratifying as they indicated the benefits derived from the use of a ground wire. He commended also the results contained in Table I on the use of buried cable to reduce tower-footing resistance. On the other hand he cited reasons why he did not agree with the authors that a direct stroke to a line conductor would provide necessarily sufficient voltage for insulation breakdown.

DO STREAMERS BUILD UP OR DOWN?

K. B. McEachron discussed the mechanism of the lightning stroke and the probability of discharges proceeding from the tower to the cloud when the cloud is negative. In the light of present evidence he believed that in order to obtain definite evidence from which to build up an adequate theory further study should be given to the determination of the manner of propagation of discharges.

1931 Lamme Medal Nominations Must be Made by October 1

Special attention is directed to the fact that the names of Institute members who are considered eligible candidates for the Lamme Medal to be awarded in the Fall of 1931 may be submitted by any member in accordance with Section I of Article VI of the By-laws of the Lamme Medal Committee, as quoted in the following:

> The committee shall cause to be published in one or more issues of the A. I. E. E. JOURNAL each year, preferably including the June issue, a statement regarding the "Lamme Medal" and an invitation for any member to present to the national secretary of the Institute by October 1 the name of a member as a candidate for the medal, accompanied by a statement of his "meritorious achievement" and the names of at least three engineers of standing who are familiar with the achievement.

Each nomination should give concisely the specific grounds upon which the award is proposed, and also a complete detailed statement of the achievement of the nominee, to enable the committee to determine its significance as compared with other candidates'. If the work of the nominee has been of a somewhat general character in cooperation with others, specific information should be given regarding his individual contributions. Names of endorsers should be given as specified above.

The Lamme Medal, founded as a result of a bequest of the late Benjamin G. Lamme, chief engineer of the Westinghouse Electric & Mfg. Company (deceased July 8, 1924), provides for the annual award by the Institute of a gold medal—together with bronze replica thereof—to a member of the A. I. E. E. "who has shown meritorious achievement in the development of electrical apparatus or machinery;" for the award of two such medals in some years if the accumulation of funds warrants.

The third (1930) Lamme Medal has been awarded to Dr. William James Foster (F '16) consulting engineer, (retired), General Electric Company, Schenectady, N. Y., "for his contributions to the design of rotating a-c. machinery;" presentation to be made during the summer convention at Asheville, N. C., June 22-26, 1931.

Edison Bust Unveiled in German Hall of Fame

Dedicated to the "spirit of indomitable research" the remarkable likeness of Thomas Alva Edison sculptured by Mrs. Evelyn Longman Batchelder was unveiled in the Hall of Honor of the Deutsches Museum, Munich, Thursday, May 7, 1931. Sponsored jointly by the Edison Pioneers and the American Institute of Electrical Engineers, this marble bust (see ELECTRICAL ENGINEERING, Jan. 1931, p. 59), was bestowed upon the museum at the time of its annual meeting presentation being made by H. H. Barnes, Jr., chairman of the joint committee of sponsors, and on behalf of the electrical engineers of America. Response to the presentation address was given by his excellency Dr. Oscar von Millar, the genius to whom credit is due for the creation of the museum and its development to the present imposing proportions. Dr. von Millar paid tribute to Mr. Edison "as a world figure and as a benefactor of humanity."

Dr. H. Schacht, chairman of the board of directors of the museum, former president of the Reichsbank, and spokesman for German interests during the drafting of the Young Plan, presided over a group of some 400 statesmen, scientists, and industrial leaders from all over Germany.

The Deutsches Museum has arranged five rooms in its electrotechnical division, one the Hall of Honor and the others devoted respectively to historic exhibits of transformers, storage batteries, transmission materials, and the industry in general. In the Hall of Honor there is installed the first dynamo made by Werner von Siemens along with other early models of dynamos. The Edison bust is one of two accorded a position in the Hall; the other is that of von Siemens. On the pedestal of the Edison bust is inscribed:

> The great inventor to whom the world is indebted for pioneering advances in the most varied fields of scientific and engineering endeavor.

On the pedestal of the von Siemens bust there is the inscription:

> The distinguished scientist and engineer whose work created the foundation of electrotechnics.

The personnel of the joint committee which handled all details for the A. I. E. E. and the Edison Pioneers included as representatives of the Institute, H. H. Barnes, Jr. (F '13), vice-president, General Electric Company, chairman; H. P. Charlesworth (F '28), vice-president, Bell Telephone Laboratories, Inc., and a vice-president A. I. E. E.; K. G. Frank, (M '14), consulting engineer of New York; and C. E. Stephens (M '22), vice-president and northeastern district manager of the Westinghouse Electric & Manufacturing Company and a director of the A. I. E. E. John W. Lieb (deceased) was the first chairman of the joint committee. Representing the Edison Pioneers were Edward D. Adams (A '10), deceased; W. S. Barstow (F '12—Life Member), president, W. S. Barstow & Co., N. Y.; G. F. Morrison, honorary vice-president of the General Electric Company; and W. H. Meadowcroft, of the Edison Laboratories.

Lighting Pioneer Dies on Pacific Coast

Augustus D. Curtis, president and founder of Curtis Lighting, Inc., died suddenly April 29, 1931, at Beverly Hills, California, at the age of 65.

His passing culminates a life devoted to the art and science of illumination, his major contribution being the active promotion of indirect lighting and the foundation of a company dedicated to the advancement of lighting. Mr. Curtis was born at Hawley, Pa., October 14, 1865, the son of a country physician.

A. I. E. E. Directors Meet in New York

THE regular meeting of the board of directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, Tuesday, May 19, 1931. Present were: *president*—W. S. Lee, Charlotte, N. C. *Vice-presidents*—W. S. Rodman, Charlottesville, Va.; C. E. Sisson, Toronto, Ont.; G. C. Shaad, Lawrence, Kans.; H. P. Charlesworth, New York, N. Y. *Directors*—E. B. Meyer, Newark, N. J.; J. Allen Johnson, Buffalo, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, A. E. Knowlton, R. H. Tapscott, New York, N. Y.; A. B. Cooper, Toronto, Ont. *National treasurer*—W. I. Slichter, New York, N. Y. *National secretary*—F. L. Hutchinson, New York, N. Y.

The minutes of the directors' meeting of March 12, 1931, were approved. The board ratified its executive committee's action of April 3, 1931, in enrolling 66 Students; electing 128 Associates, 6 Members, and 1 Fellow; transferring 15 to Member grade and 5 to Fellow grade.

Reports of board of examiners' meetings of March 25 and April 29 were presented and approved. Upon the recommendation of the board of examiners, 138 Students were enrolled; 87 Associates were elected; 6 Members were elected; 6 applicants were transferred to the grade of Member.

Approval by the finance committee, for payment, of monthly bills amounting to $30,268.77, was ratified.

The national secretary reported 1,805 members in arrears for dues for the fiscal year which ended April 30, 1931, and was directed to transfer their names from the mailing list (after the distribution of the June and July issues of ELECTRICAL ENGINEERING) to a "suspended" list, and to employ the usual methods of collecting these dues and restoring the members to the active membership list.

The annual report of the board of directors to the membership for the fiscal year which ended April 30, 1931, as prepared under the direction of the national secretary, was considered and approved for presentation at the annual meeting of the Institute at Asheville, N. C., June 22.

The national treasurer presented a report covering the fiscal year just closed. Annual reports of the general standing committees (exclusive of the reports of the technical committees, which will be presented at the summer convention in June) were received. Abstracts of these reports were incorporated in the board of directors' annual report.

The national secretary submitted a report relating to several proposed Institute activities and upon his recommendation the president was authorized to appoint a special committee to study and report upon present and proposed Institute policies.

Authorization was given to the meetings and papers committee to schedule two papers by non-members for the summer convention.

The report of the committee on award of Institute prizes, of the awards made covering the year 1930, was presented and accepted.

Upon the recommendation of the standards committee, (1) approval was given to a minor revision of A. I. E. E. Standard No. 26 on "Automatic Stations," made by the committee on automatic stations; (2) approved for presentation to the American Standards Association for consideration as an American Standard, "Symbols for Mechanics, Structural Engineering, and Testing Materials," prepared by the sectional committee on scientific and engineering symbols and abbreviations. As a member-body of the American Standards Association, the Institute's approval was given to proposed revisions of the constitution of that organization.

A report was presented of a special committee appointed upon the recommendation of the delegates' conference at the 1930 summer convention, to consider membership grades in the Institute (below that of Member), entrance and transfer fees, etc. This report, in effect, recommended that no change be made at this time in the present arrangement of including all members below the grade of Member in the single grade of Associate, and that the entrance and transfer fees now in force be continued. Report approved.

In accordance with Section 37 of the Institute's constitution, consideration was given to the appointment of a national secretary for the administrative year beginning August 1, 1931. F. L. Hutchinson, present national secretary, was reappointed, and a resolution was adopted expressing the board's appreciation of the value of his services.

As a result of a communication from the Polish Association of Electrical Engineers, suggesting cooperation, the secretary was authorized to make arrangements with that organization for the exchange of membership privileges for visiting members, similar to the arrangements in force with several other foreign engineering societies.

An invitation to send delegates to the Fourth Pan American Commercial Conference, in Washington, October 5-12, 1931, was accepted and the president was empowered to appoint the delegates.

Other matters were discussed, reference to which may be found in this and future issues of ELECTRICAL ENGINEERING.

Who Received The First E. E. Degree?

Recent efforts upon the part of Institute headquarters to answer the question as to what American college was the first to award a degree in electrical engineering resulted in the collection of the following interesting information:

The Tufts College catalogue for 1882-83 contained an announcement of a course in electrical engineering arranged in connection with other departments of instruction extending over a period of three years and leading to a special degree.

In June 1883, F. S. Pearson received a degree in civil engineering at Tufts College, and in 1885 he was awarded a new diploma containing recognition of the fact that he had completed the course in electrical engineering. Thus, while the use of the expression "electrical engineering" in connection with a degree was first used at Tufts College in 1885, it was made retroactive by the issuing of a new diploma.

Lehigh University announced in its catalogue for 1883-84 a special advanced course in electrical engineering requiring one year for completion. The first class entered in the fall of 1884 and completed the work in June 1885, receiving certificates but not degrees. The first degrees in electrical engineering at this university were awarded in 1891.

The Massachusetts Institute of Technology announced August 1, 1882, the establishment of a four-year curriculum in electrical engineering under the administration of the department of physics, beginning with the opening of the academic year 1882-83. Two degrees for completion of this curriculum were awarded in 1885.

The Cornell University curriculum in electrical engineering was established early in 1883 as an offshoot of the department of physics, and the first degrees were awarded in 1885.

Additional information regarding early degrees in electrical engineering will be deeply appreciated by the Institute headquarters staff. Address correspondence to Henry H. Henline, assistant national secretary, A. I. E. E., 33 West 39th St., New York, N. Y.

Institute Priz Awards Announced for 1930 Papers

FOUR national prizes for papers submitted during the calendar year 1930 have been announced by the committee on award of Institute prizes, which committee consists of A. E. Knowlton (F '30) chairman, L. W. Chubb (F '21) and W. S. Gorsuch (M '17). These prizes in each case consist of $100 in cash and suitable certificates; in cases of joint authorship the cash to be divided. Personal presentation of the prizes will take place at the first session of the Institute's summer convention at Asheville, N. C., June 22-26, 1931.

District prizes as announced by five Districts include ten awards of $25 each together with appropriate certificates. As in the case of the national prizes, where there is a joint authorship the cash awards are divided.

NATIONAL PRIZES

First prize for theory and research, awarded jointly to R. H. Park (A '27) and W. F. Skeats (A '27) for their paper "Circuit-Breaker Recovery Voltages" presented at the Middle Eastern District meeting, Philadelphia, Pa., October 13-15, 1930.

First prize for engineering practise, awarded to V. M. Montsinger (F '29) for his paper "Loading Transformers by Temperature" presented at the winter convention, New York, January 27-31, 1930.

Honorable mention was made of the paper by W. B. Kirke (A '19), "The Calculation of Cable Temperatures in Subway Ducts" presented at the North Eastern District meeting, Springfield, Mass., May 7-10, 1930.

No prize was awarded in the field of public relations and education.

NATIONAL PRIZE FOR INITIAL PAPER

Initial-paper prize awarded jointly to E. E. George (M '29) and R. H. Bennett, Jr., (A '25) for their paper "Directional Ground Relays" presented at the summer convention, Toronto, Ont., June 23-27, 1930.

Honorable mention given to E. T. J. Brandon (F '20) for his paper "The 220,000-Volt System of the Hydro-Electric Power Commission of Ontario" presented at the summer convention, Toronto, June 23-27.

NATIONAL PRIZE FOR BRANCH PAPER

Branch-paper prize awarded jointly to J. R. Outt and E. H. Pemberton for their paper "Neutral Grounding Reactors for Power Systems" presented at a joint meeting of the University of Colorado Branch and the Denver Section, May 24, 1930.

Honorable mention made of the paper by G. W. Barnes "A Vacuum-Tube Wattmeter" presented at a meeting of the Oregon State College Branch, May 24, 1930.

DISTRICT PRIZES

District No. 1

First prize awarded to J. E. Clem (M '30) for his paper "Arcing Grounds and Effect of Neutral Grounding Impedance" presented at the North Eastern District meeting, Springfield, Mass., May 7-10, 1930.

Initial-paper prize awarded to F. R. Longley (A '25) for his paper "The Calculation of Alternator Swing Curves" presented at the North Eastern District meeting, Springfield, Mass., May 7-10, 1930.

Branch-paper prize awarded to F. K. Fischer for his paper "Magnetic and Electrical Properties of Some Chromium-Steel Alloys" presented at the student Branch convention, Springfield, Mass., May 9, 1930.

District No. 6

Branch-paper prize awarded jointly to J. R. Outt and E. H. Pemberton for their paper "Neutral Grounding Reactors for Power Systems" presented at a joint meeting of the University of Colorado Branch and the Denver Section, April 18, 1930.

District No. 8

First prize awarded jointly to F. E. Terman (A '13), D. E. Chambers (A '30), and E. H. Fisher (A '30) for their paper "Harmonic Generation by Means of Grid-Circuit Distortion" presented at the Pacific Coast convention at Portland, Ore., September 2-5, 1930.

Honorable mention was made of a paper by E. R. Stauffacher (M '26) "Development of a Relay Protective System on the Lines of the Southern California Edison Company, Ltd." presented at the Pacific Coast convention, Portland, Ore., September 2-5, 1930.

District No. 9

First prize awarded jointly to F. O. McMillan (M '26) and E. O. Starr (M '29) for their paper "The Influence of Polarity on High-Voltage Discharges" presented at the Pacific Coast convention, Portland, Ore., September 2-5, 1930.

Initial-paper prize awarded to E. O. Goodale (A '27) for his paper "Errors in Power Metering" presented at a meeting of the Seattle Section, May 20, 1930.

Branch-paper prize awarded to Lowell Hollingsworth for his paper "A Visual Lichtenberg Figure Voltmeter" presented at a meeting of the Oregon State College Branch, May 24, 1930, and at the Pacific Coast convention, Portland, Oregon, September 2-5, 1930.

Honorable mention was made of a paper by H. D. Garrison and L. E. Steele, "The Development of a Tesla Coil," presented at a joint meeting of the Seattle Section and University of Washington Branch, April 15, 1930.

District No. 10

First-prize awarded to T. R. Rosebrugh (A '91) for his paper "The Analytics of Transmission Calculations" presented at the summer convention, Toronto, Ont., June 23-27, 1930.

Initial-paper prize awarded to T. R. Rosebrugh for his paper "The Analytics of Transmission Calculations" presented at the summer convention, Toronto, Ont., June 23-27, 1930.

V. D. I. Celebrates Its 74th Anniversary

On May 12, celebrating the seventy-fourth year of its existence, the Verein Deutscher Ingenieure unveiled at Alexisbad, Germany, a statue as a memorial to its founders and their aim "to coordinate the efforts of the best technical brains for the benefit of the whole industry of the country." Today the V. D. I. has 31,000 members in 53 districts and 29 local branches in Germany besides three foreign branch societies, one each in China, Argentina, and Japan.

In addition to this memorial the V. D. I. annual meeting to be held at Cologne June 27-29 will be in the form of a jubilee celebration, although true to its traditions as a scientific body, scientific events will be the chief attraction. A lecture on radiation problems, emphasizing the relation between engineering and modern physics will be the principal item of the program.

Coffin Fellowships Awarded to College Graduates

Nine college graduates have been granted fellowships for the collegiate year 1931-1932 by the Charles A. Coffin Foundation, a creation of the General Electric Company. The fellowships are to enable the recipients to engage in technical research and post-graduate work in various educational institutions. The recipients are:

J. L. Oncley, of Winfield, Kan., graduate of University of Wisconsin, to study at that institution.

E. E. Postel, of Cleghorn, Ia., a senior at University of Illinois, to study at the University of Iowa.

A. P. Gagge, of Richmond, Va., graduate of University of Virginia, to study at Yale.

G. H. Fritzinger, of Bryant, Ind., graduate of Wittenburg College, to study at Purdue University or at Massachusetts Institute of Technology.

H. E. Darling (Assoc. Student, A. I. E. E.), of Pawtucket, R. I., graduate of Brown University, to study at that institution.

J. P. Fugassi, of Pittsburgh, graduate of Carnegie Institute of Technology, to study at University of Wisconsin.

O. C. Simpson, of Champaign, Ill., graduate of University of Illinois, to study at that institution.

M. Nelles, of Madison, S. D., graduate of University of South Dakota, to study at Harvard.

D. H. Sloan, of San Francisco, graduate of Washington State College, to study at University of California.

Of these men two, Simpson and Sloan, received fellowships under the Foundation last year.

"Plan Your Vacation to Include Tahoe Convention"

As the plans for a splendid technical and social program for the A. I. E. E. 1931 Pacific Coast convention at Lake Tahoe, California, Aug. 25-28, are reaching the final stages, added inducements have developed unexpectedly. These combine with the many program features to make attendance at the convention doubly desirable.

Members of the Institute who plan to combine work and play in their vacation schedule by attending the convention may spend the week preceding or following the convention at Tahoe Tavern with the low convention rates applying during their entire stay. Since the management of Tahoe Tavern has offered the convention the attractive rates of $7.00 to $8.00 per day per person, American plan, many members are planning to take advantage of this splendid opportunity to spend the week-end before or after the convention enjoying the famous Lake Tahoe scenery.

For those traveling by automobile, several scenic routes are available through many points of historic interest. Railroad transportation to the convention is by the Overland Route of the Southern Pacific. Low summer round-trip fares with attractive stopover privileges are available from all parts of the country.

Light and Vision

The February 1931 issue of the *Transactions of the Illuminating Engineering Society* contains an analysis of the literature concerning the dependency of visual functions upon illumination intensity compiled in the form of a report prepared for the national committee on industrial lighting of the national Research Council by Dr. L. T. Troland, Lecturer on Psychology, Harvard University, Cambridge, Mass., and Head of Research Department, Technicolor Motion Picture Corp., Boston, Mass.

Prof. J. W. Barker (F '30, dean of the Columbia University school of engineering) in an editorial, in the same issue, says in part:

"In the paper which forms the body of this issue of the *Transactions*, Dr. Troland has assembled a bibliography of more than nine thousand sources from which he has critically analyzed and correlated the contents. Many portions of this analysis will be of great interest and assistance to the practical engineer, and the analysis in its entirety will serve as a compendium of reference material to which we may refer as an analytical background for much of our specialized work."

The scope of this analysis is indicated by the headings given below, taken from the table of contents of the report in question:

TABLE OF CONTENTS

I. Preface

II. Method and scope of literature search

III. Abstract of the literature bearing on the dependency of visual functions upon intensity of the stimulus

1. General survey of the problem
2. Absolute sensitivity to light
    - References on absolute energy and brightness thresholds
    - References on areal relations of the thresholds
    - References on light and dark adaptation
3. Fechner's law: discrimination of reflection coefficients of large areas
    - References on brightness discrimination threshold
4. Dependency of visual acuity upon illumination intensity
    - References on visual acuity, general
    - References on visual acuity as a function of intensity
    - References on glare
5. Speed of vision as determined by intensity
    - References on speed of vision
6. The dependency of color vision upon intensity
    - References on color and intensity
7. Oculomotor functions, eye-strain, fatigue and injury
    - References on the pupil and other oculomotor functions
    - References on eye-strain and fatigue
    - References on injury to the eye due to light
8. The influence of illumination intensity upon practical operations
    - References on illumination intensity and practical operations
    - Miscellaneous references
9. Summary and conclusion

Prof. Barker, in closing his editorial, says: "In publishing this analysis the Illuminating Engineering Society feels that it is making available to the world a monumental piece of work for which it thanks Dr. Troland the National Research Council."—*An "Illumination Item" contributed by G. S. Merrill, chairman A. I. E. E. committee on production and pplication of light, Nela Park, Cleveland.*

Personal

R. E. Doherty Accepts Yale Professorship

R. E. Doherty (M '27) for many years consulting engineer of the General Electric Company, Schenectady, N. Y., and formerly a personal assistant to Dr. C. P. Steinmetz, will become professor of electrical engineering at Yale University this fall. He will succeed Prof. C. F. Scott (HM '29 and past-president) whose retirement takes place a year from this date. Mr. Doherty is a graduate of the University of Illinois. From the student training course at Schenectady, he worked for two years in the General Electric Company's testing department; then joined the a-c. engineering department as proposition designing engineer. His work attracted the attention of Dr. Steinmetz and in 1920 he chose Mr. Doherty as his assistant. During this period of service with the "electrical wizard" he was doing postgraduate work at Union College and in 1921 he received his master of science degree. In 1922 he became the company's consulting engineer and as such achieved monumental record. In addition to his consulting work he has had charge of the company's advanced course in engineering, a three-year course in design engineering specially planned for a small selected group of college graduates. He was a member of the G. E.'s general education committee and is deeply interested in all educational matters. For three years (1918-19 and 1926-28) he served on the Institute's educational committee. He has been a member also of the A. I. E. E. committees on electrophysics (1924-26) and power transmission and distribution (1928-29); during the period 1926-27 he served as chairman of the Schenectady local Section. He has contributed much also to technical literature.

S. M. Kintner (M '13) for some time assistant vice-president of the Westinghouse Electric and Manufacturing Company was elected its vice-president in charge of engineering at the April 29 meeting of the board. He succeeds W. S. Rugg (M '13) whom the company has made vice-president in charge of sales. As an Institute member, Mr. Kintner has been active on its committees as follows: telegraphy and telephony 1914-15; research 1927-29; representative to National Research Council, engineering division 1928-29; chairman of the research committee and on the board of award of Institute prizes 1929-30.

R. E. DOHERTY

S. M. KINTNER

J. E. OLEM

North Eastern District 1930 Prize Winners

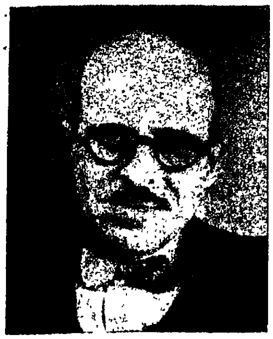
F. K. Fischer, a member of the A. I. E. E. student Branch at Rensselaer Polytechnic Institute received the 1930 Branch Paper prize for his paper "Magnetic and Electrical Properties of Some Chromium Steel Alloys" presented as a part of the program of the North Eastern District meeting at Springfield, Mass., and the basis of the thesis upon which Mr. Fischer earned his E. E. degree at time of graduation June, 1930. This thesis has since been published as a Rensselaer Polytechnic Institute Bulletin, Engineering and Science Series. In July Mr. Fischer joined the student Test Course of the Westinghouse Electric and Manufacturing Company at East Pittsburgh and at present is a member of the Westinghouse Mechanical School of Design run in cooperation with the Graduate School of the University of Pittsburgh.

J. E. Clem (M '30) received the 1930 Best Paper prize of the North Eastern District, A. I. E. E., for his paper "Arcing Grounds and Effect of Neutral Grounding Impedance" presented at the Springfield meeting of the District in May, 1930. Mr. Clem was graduated from the University of Colorado in 1910 with the degree of B. S. in E. E. During the summer of that year he joined General Electric staff in Schenectady, N. Y. In 1922 he went to Japan to supervise the initial installation of 154-kv. transformers in that country, returning in 1925 to become a member of the central station engineering department at Schenectady. Mr. Clem is the author of several Institute papers, and is active in Institute affairs.

F. R. Longley (A '25) received the North Eastern District's 1930 First Paper prize for his paper "The Calculation of Alternator Swing Curves" presented at the District meeting in Springfield in May, 1930. Mr. Longley was graduated from the Georgia School of Technology, Atlanta, in 1923 with the degree of B. S. in E. E. During that summer he joined the General Electric staff in Schenectady where he spent time "on test" and subsequently in the a-c. engineering department. Later, in the central station engineering department he made a special study of stability problems. Mr. Longley left the employ of the General Electric Company in July, 1930, to become associated with the Western Massachusetts Companies with headquarters in Springfield.

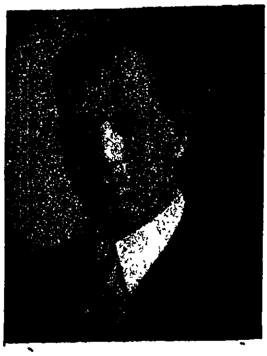
B. M. Jones (M '24) general engineer of the Duquesne Light Company, Pittsburgh Pa., has become the comp ny's planning engineer, and as such will be directly responsible for the planning and development of the Duquesne system as well as the preparation and administration of the capital improvement budget. For many years Mr. Jones has taken an active part in Institute affairs as member of the relay subcommittee and the oil circuit breakers, switches, and fuses subcommittee of the protective devices committee (still serving); and the membership committee of the Pittsburgh Section. He has done considerable work in connection with the committee on uniform procedure for testing oil circuit breakers for interrupting capacity; was joint author with G. B. Dodds in the presentation of "Ground Relay Protection for Transmission System" at the Detroit A. I. E. E. summer convention.

E. J. Jonas (M '23) is the new president of the Central Electric Railway Master Mechanics' Association, Toledo, Ohio. His success as superintendent of the Cincinnati Street Railway Company has made him eminent in mechanical and electrical engineering circles in Cincinnati, as did his work on the standing committee of the Institute's local Section there; he also has served twice on the A. I. E. E. nominating committee. Two years ago he was elected vice-president of the



F. R. LONGLEY

F. K. FISCHER



R. W. E. MOORE

Master Mechanics' association, and its program committee chairman.

Chester Lichtenberg (M '13) who has been intimately identified with technical committees of the Institute, the N. E. L. A., N. E. M. A., and the War Department's procurement planning activities, recently was appointed engineer of the electric refrigeration department at the Fort Wayne Works of the General Electric Company, after nearly twenty-five years with that company in the development of switchboard apparatus, particularly in connection with high-speed air circuit breakers, oil circuit breakers, and selective protective relays.

E. A. Olsen (M '24) formerly vice-president of the Pacific Public Service Company and managing head of its public utility properties serving California, Oregon, and Washington communities, has accepted the position of executive vice-president of the Oklahoma Natural Gas Corporation with offices at Tulsa. Associated with the Insull interests Mr. Olsen held similar office with the Florida Power Corporation and the Georgia Power & Light Company.

R. W. E. Moore (M '17) who until June 1 was with the Westinghouse Company at East Pittsburgh, Pa. as manager of association activities, has been appointed by the National Electric Manufacturers Association to take charge of its publications. For many years Mr. Moore was a member of the Electrical Manufacturers Council as well as chairman of the NEMA Fire Prevention committee.

Alexander E. Bettis (F '26) one of the Institute's directors, and at present serving on its safety code, production and application of light, and transportation committees for 1931, has been chosen president of the Missouri Association of Public Utilities. Mr. Bettis is at present serving the Kansas City Power & Light Company as its vice-president. In 1926-28 he was vice-president of the Institute's South West District.

J. W. Young (A '22) who as engineer of the Narragansett Electric Company went to Providence two years ago to participate in distribution system improvement, has been transferred to the Boston office of the New England Power Association to serve as assistant distribution engineer under W. C. Phillips (M '30) in charge of the development of retail properties of the organization.

W. H. McGrath (M '20) formerly vice-president of the Puget Sound Power & Light Co., Seattle, Wash., has been made its executive vice-president and C. C. Curtis (M '23) previously vice-president in charge of the Fall River Gas Works, Fall River, Mass. has been appointed manager to supervise the Puget Sound Company's operations in its southern, southwestern, and western districts.

Thos. E. Penard (A '08) who during his many years of service with the company has specialized in station design and substation development as head of the electrical division of the Edison Electric Illuminating Company of Boston has been appointed recently to the office of assistant superintendent of its station engineering department.

Gerard Swope, (F '22) addressed the plenary session of the sixth general congress of the International Chamber of Commerce meeting May 4-9, 1931, Washington, D. C., taking as his subject "Regularization of Employment", and presenting the various points of view of company, trade and industry, society, and employe.

L. C. Halpin (A '26) until recently meter superintendent for the Western division of the Niagara Lockport and Ontario Power Company, has been made rural representative of the Angola district in charge of distribution. Mr. Halpin is a member also of the Western Society of Engineers.

Karr Parker (M '24) well known in the Westinghouse organization as president of that company's Agent Jobbers Association, is the newly elected president of McCarthy Bros. & Ford, Buffalo, N. Y., Westinghouse jobbers. He succeeds E. D. McCarthy whose death occurred recently.

H. T. Edgar (M '28) who entered the public utility field in 1886 as an employee of the Edison Electric Illuminating Company of Brunswick, N. J., and for the past thirty-two years associated with Stone & Webster in managerial work extensively throughout the country, has resigned from that organization.

A. M. Chitty (M '22) who has succeeded R. C. Saunders as southwestern district manager of the Puget Sound Power & Light Company, with headquarters at Tacoma, Wash., has a record of long standing with these interests, having been for many years superintendent of the company's traction properties.

Frank W. Smith (M '12) vice-president and general manager of the United Electric Light & Power Company, New York, N. Y. and a former president of the National Electric Light Association, now is vice-president of the New York Edison Company as well.

A. R. Nissar (M '16) principal of the Calcutta Technical School, Bengal, India, left Calcutta the first week in April 1931 for an extended trip to France, Italy, Switzerland, Holland, Germany, and Great Britain.

J. H. Cerecedo (A '20) of the firm of J. H. Cerecedo & Company, Santurce, Porto Rico, Pan-American consultants, has announced the opening of an office in the United States in Chicago, at 105 South La Salle Street.

J. S. Edstrom (F '14) managing director of the General Electric Company interests in Sweden, recently visited the United States as a delegate to the World Congress of the International Chamber of Commerce, Washington, D. C.

R. H. Manahan (M '22) who is chief of the Department of Electricity of the City of Los Angeles and for many years active in the affairs of the International Association of Electrical Inspectors, now has become its national president.

F. R. Phillips (M '27) for some time senior vice-president of the Philadelphia Company was elected president of that company at the April 28 stockholders' meeting.

Obituary

Edward Dean Adams (A '10), engineer, financier, scientist, whose vision, industry, courage, and philanthropy has made possible many achievements of outstanding worth to humanity, including the conception and development of the Niagara Falls hydroelectric system, passed away at his home in New York City May 20, 1931. His death, it is believed, was due almost directly to an automobile accident which occurred while he was en route to Florida in March. Primarily a financier and promoter of innumerable engineering and philanthropic projects, Dr. Adams was born in Boston, Mass. April 9, 1846. From college days on, he has been the recipient of almost countless honors; his degrees (B. S. 1864, M. S. 1897, LL.D. 1906 and M. A. 1908) were followed by titles of both national and international merit including the Royal Order of the Crown of Prussia (1909) and the Médaille de Réconnaissance of the French Republic (1921). In 1926 he received the John Fritz Medal "for great achievement as an engineer, financier and scientist;" he was patron and Life Member of the American Association for the Advancement of Science; patron and Fellow for Life of the American Fine Arts Society; Fellow for Life of the American Geographical Society; and Life Member of the National Geographical Society, the Massachusetts Institute of Technology Alumni Association, the New York Academy of Science, New York Historical Society, Germanistic Society of America, New York Botanical Garden (of which he also was manager and past officer 1912-19), Society of the Sons of the Revolution, New York Geneological and Biographical Society; a Fellow in Perpetuity of the Metropolitan Museum of Art, the Museum of Natural History and the National Academy of Design; a member of the Edison Pioneers; a Fellow and member of the Power Division of the American Society of Civil Engineers; a member of the executive board, engineering division, and electric insulation committee of the National Research Council. Since its inception he has held the chairmanship of the Committee on War Memorial to American Engineers which controlled the building and bestowal of the worldwide famous carillon installed and dedicated at the University of Louvain, Liege, Belgium, July 4, 1928. As a past-officer and director, has included in his activities the promotion of few less than a hundred industrial, educational, and charitable organizations. From 1922 to 1924 he was chairman of the Institute's Edison Medal Committee and from 1916 to the date of his death has represented the Institute on the Engineering Societies' Library Board and in the United Engineering Trustees, Inc. His membership in twenty-seven of the prominent clubs, local and otherwise, including the Engineers Club of New York, the Technology Club (Life Member), Faculty Club of Columbia University, Grolier Club, New York Railroad Club, Lawyers Club, Metropolitan Club, Mendelssohn Glee Club, Economic Club of New York, the Chicago Club and the Adirondack League Club, conveys some intimation of the breadth of application of his activities. Science, art, industry, education, and charity in every community in which he has had his being have benefited by his generosity.

Charles Day (A '02) chairman of the board of Day & Zimmerman, Inc., Philadelphia, Pa., and an expert in plant operation, died at the University Hospital, Philadelphia, May 10, 1931 after an illness of ten days, with which he was stricken a few days subsequent to his return from a trip to North Africa. Philadelphia was his native city; in boyhood he attended the Germantown Academy and in 1899 he was graduated from the department of electrical engineering, University of Pennsylvania. That summer he worked in the engineering department of the National Export Exposition, later associating himself with the Link Belt Engineering Company. As an acknowledged authority on industrial plant equipment and management of public service corporations, he lectured before the Graduate School of Business Administration at Harvard and Columbia universities. At the beginning of the World War he was made trustee of the Emergency Fleet Corporation and during the war served also as a member of civilian board to investigate the efficiency of the Navy Yards. In the winter of 1917 he attended the war council of the Allies and as one of the Storage Committee of the General Munitions Board he conferred with General Pershing and French officials in an effort to speed the transportation of troops and supplies to Europe. He was appointed by the Secretary of War to the Depot Board. He was engineering advisor to Colonel House, a member of the board of management of Franklin Institute, a trustee of the University of Pennsylvania, and a member of the American Society of Mechanical Engineers; also he was a director of the Pennsylvania Railroad, the Philadelphia Fidelity and Trust Company and the United Gas Improvement Company of which his partner Mr. John E. Zimmerman was president. Socially, his memberships included the Engineers' Club (Philadelphia and New York), the Aero Club of America, the Huntington Valley Club and the Raquette Club. His contributions to technical literature were many and his book "Industrial Plants" has had wide circulation.

Stanley L. B. Lines (M '18) vice-president of the Sangamo Company, Ltd., of Toronto, Canada, died at his home there April 9, 1931. He was born in Shire Newton, England in 1884, and received his early education in English private schools. With Brockie Pell Lamp Company, London, he was an honor pupil for three years and also attended evening classes at the City and Guilds Technical Institution for another three years. After completing an apprenticeship with the British Thomson-Houston Company, he joined the technical staff of the Chamberlain & Hookham Company of England, and as its special representative traveled to almost every known continent, finally establishing and managing the Canadian branch of the company at Toronto. In 1919 with Prof. P. M. Lincoln, under whose patents the work was largely carried on, he organized at Toronto the Lincoln Meter Company, Ltd., (producers of a large line of measuring devices) he himself acting in the capacity of vice-president and manager. In 1930 this company was absorbed by the Sangamo Electric Company of Canada, the company of Mr. Lines' final affiliation. His was a long and noteworthy record with the electrical industry of Canada, conspicuous in conjunction with the Canadian Electrical Association and his work as a member of its meter committee. He was past-president of the Electric Club of Toronto, an Associate Member of the Institution of Electrical

Engineers in England, a member of the Association of Professional Engineers of Ontario and belonged to numerous clubs and technical organizations. He was a survivor of the Lusitania disaster.

W. S. Richmond (A '15) secretary, treasurer, and general manager of the Marseilles Land and Water Power Co., Ottawa, Canada, died April 11, 1931. He was a native of Cheshire, Mass. and 50 years of age. Upon graudation from the Adams High School in 1901, he immediately entered upon his technical training at Massachusetts Institute of Technology from which he was graduated with the degree of B. S. in civil engineering June, 1905. Early in 1909 he was first assistant to the resident engineer of the United States government determining the efficiencies of generating units of the Niagara Falls Power Company; later that same year he engaged in a similar capacity at Sault Ste. Marie, Michigan, in connection with government tests of plants of Lake Superior Power Company, the Edison Sault Electric Company and the Lake plants in Michigan. In 1914 the United States government engaged him as resident engineer in full charge of determining efficiencies of generating units in the plants of the Hydraulic Power Company at Niagara Falls. More recently he was civil engineer with the United States Lake Survey (of the War Department) in charge of government surveys of harbors on the east coast of Lake Michigan.

Clark E. Baker (A '21), a member of the transportation engineering department of the General Electric Company at Erie, Pa., and for a number of years a resident of Schenectady, died at his home in Erie on May 11 after a short illness. He was graduate of California Institute of Technology, Pasadena, in 1917 and went to Schenectady in June of that year on the student training course. In September he entered the army engineering corps and continued in service until March, 1919.

Resuming work at Schenectady he was transferred in August, 1919, to the company's railway engineering department, specializing on substation equipment applications. In September, 1929, he moved to Erie with the department and was placed in charge of the substation section.

He was born at Paw Paw, Illinois, December 19, 1894, but the family early removed to Santa Ana, California, where both parents now are living. He is survived by his wife, Myrtle Van Allen, and two children, a boy of 7 and a girl of 5. He was active in American Institute of Electric Engineers affairs, serving on committees and contributing to the proceedings. Interment was at Santa Ana, California.

Robert McRae Wilson (A '24) electrical engineer of the General Electric Company, Bloomfield, N. J. and resident of Montclair, N. J., died suddenly April 24, 1931, while in Savannah, Ga. on a motor trip. He was a native of Beaufort, S. C., but his technical education was acquired in the State of New York—two years at City College of New York and the regular four-year course at Cornell University from which he was graduated in 1896. The following year he engaged with the Hyer Sheehan Electric Motor Company of Newburgh, N. Y., for eighteen months general engineering and estimating work; then he joined the Sprague Electric Company at Bloomfield, N. J. The next year he became instructor in electrical engineering at Lehigh University, but at the end of one semester returned to the Sprague company and remained with it after it became the Sprague Electric Works of the General Electric Company; later the Bloomfield Works of that company. Mr. Wilson's term of service, extending over a period of thirty years, included considerable specialized work on d-c. motor and generator design.

Edward B. Plenge (A '22) electrical engineer of the waterwheel generator section of the a-c. engineering department of the General Electric Company, Schenectady, N. Y., died April 3, 1931 due to injuries sustained by being struck by an automobile. He was born in Charleston, S. C. in 1886, and was graduated from Clemson College in 1907, having completed its course in electrical engineering. In August of that year he engaged in the G. E. Test Course at the Schenectady works, and in October 1909 joined the a-c. engineering department of the company, where he has remained in continuous service. He has had charge of the design work on waterwheel-driven generators for a number of years during a period when General Electric achievement in this field included generators for the Conowingo Dam, the 65,000-kw. units at Niagara Falls, and the 77,500-kw. units for the U. S. S. R. Mr. Plenge's home was in Scotia, New York, where he was held in high esteem by both his professional and personal friends. He was a member of the Edison Club and of the Schenectady Country Club.

McKee Duncan (A '14) consulting engineer of Duncan, Young & Company, New York City, met with sudden death on the public golf course at Van Cortlandt Park there. He was 43 years of age. In 1910 the degree of B. S. was conferred upon him by Columbia University; later in that same year he went to Europe for graduate work in physical chemistry at the University of Leipzig. Returning to the United States in 1911, he continued the study of physical chemistry at the University of Wisconsin. His early commercial connection brought him in close association with Dr. Louis Duncan as a member of the firm of Duncan, Young & Pressey, Inc., predecessors of the company of his last affiliation, and was heartily endorsed by him for membership in the Institute after a friendship which had endured for over twenty years.

Joseph T. Blondin (A '18) director of the Revue Générale de l'Electricite, France, passed away at the home of his son in Paris, April 21, 1931. He was in the 68th year of his age. Born in Dieppe, he led a most active professional career, held in high esteem by his countrymen. He was well-known as an electrical engineer, and bore the honorary titles of Officer d'Academie, Officer de l'Instructions Publique and Chevalier du Merite Agricole. He was also professor of mathematics and professor of physics at several of the representative universities of France, including Orleans and the College of Rollins. Many of the French technical publications were issued under his directorate.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicat them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Collinot, Marcel A., 88 Sherman Ave., Newark, N. J.

DiLucci, A., Box 1051, Chicago, Ill.

Duane, George B., Otis Elevator Co., Yonkers, N. Y.

Muncy, V. E., Ohio Mechanics Institute, Cincinnati, Ohio.

O'Shea, V., Jr., 115 Broadway, New York, N. Y.

Tung, C. T., c/o Stone & Webster Engg. Corp., Hopewell, Va.

Local Meetings

Florida Section Organized

At its meeting held on January 28, 1931, the Institute's board of directors authorized the formation of the Florida Section to cover the entire state.

This Section held an organization meeting March 27th, at which the following officers were elected: Prof. Joseph Weil (A '24) chairman; C. S. Hammatt (M '23) vice-chairman; R. P. Smith, secretary-treasurer; H. N. Fairbanks, member executive committee.

Student Convention at Rose Polytechnic Institute

The annual student convention of the Branches at Purdue University, University of Illinois, and Rose Polytechnic Institute was held at Rose Polytechnic Institute April 18, 1931; total attendance 120.

The afternoon was devoted to an inspection trip to the Dresser plant of the Indiana Electric Corporation, and the mine operating in conjunction with it. Addresses of the evening were:

Railway Electrification, by W. D. Bearce (M '30), General Electric Company.

The Operation of Large Electric Power Plants, by L. B. Andrus (F '19) president, Indiana Electric Corporation.

North Central District Holds Student Activities Conference

The fifth annual conference on student activities in District No. 6 was held at the University of North Dakota (Grand Forks) on April 17-18, 1931. Of the nine schools in the District, eight were represented by both counselors and chairmen.

Friday Evening

In the absence of Thomas F. Kane president of the University of North Dakota, the address of welcome was given by Dr. William G. Bek, dean of the junior division. Dean H. S. Evans (M '09) vice-president, District No. 6, responded for the delegates and then presided during the presentation of the following program:

Report of summer convention of the A. I. E. E. held June 1930 at Toronto, Ont., Canada, by Prof. G. H. Sechrist (A '20) counselor, University of Wyoming Branch, and chairman of the district committee on student activities.

Personal Qualities Which a Branch Chairman Should Develop to be a Successful Leader of His Branch, Prof. W. C. DuVall (M '20) counselor, University of Colorado Branch, Prof. F. W. Norris (M '26) counselor, University of Nebraska Branch.

Formal discussion presented by Neil Sanders, chairman, University of Wyoming Branch.

The Effect of Electricity Upon the Human Body, by R. B. Witmer, Asst. Prof. of Physics, University of North Dakota.

After the completion of the program the business meeting of the counselors and an informal meeting of the Branch chairmen were held in parallel session. Prof. G. H. Sechrist (A '20) chairman, District committee on student activities, presided at the former.

The counselors decided that the sixth annual conference will be held in the spring of 1932 at the University of Denver.

Prof. H. F. Rice (A '21) counselor, University of North Dakota Branch was elected chairman of the committee on student activities for the ensuing year and delegate to the summer convention at Asheville. Prof. D. R. Jenkins (A '16) counselor, University of North Dakota Branch was elected alternate delegate.

Saturday Morning

Vice-president Evans presided.

Should Qualifications for the Grade of Enrolled Students be Established?, by Prof. B. B. Brackett, counselor, University of South Dakota Branch.

Formal discussion presented by B. J. Shields, chairman, University of North Dakota Branch.

Should Attendance at Student Branch Meetings be Made Compulsory and Credit Given for this Work?, by Prof. H. F. Rice, counselor, University of North Dakota Branch, presented by Charles C. Libby.

Formal discussion presented by A. Steponaitis, University of South Dakota Branch.

What the Prospective Employer Looks for in the Engineering Graduate, by Prof. H. S. Rush (M' 30) counselor, North Dakota Agricultural College Branch.

Formal discussion presented by Almon Bjerke, chairman, South Dakota State School of Mines Branch.

What Can the Institute do Through Its Branches to Inform High School Students of the Opportunities and Need for Trained Electrical Engineers, by Prof. J. O. Kammerman (M' 20) counselor, South Dakota State School of Mines Branch.

Formal discussions presented by R. M. Partington, chairman, University of Colorado Branch, and H. H. Ward, chairman, University of Denver Branch.

How Best May the Branch Serve in the Development of Its Members as Engineers?, by Prof. R. E. Nyswander (M '22) counselor, University of Denver Branch.

Formal discussions presented by Phil Ehrenhard, chairman, University of Nebraska Branch, and C. E. Bryant.

San Francisco Section Meets with Branches

The annual joint meeting of the San Francisco Section and the student Branches at the University of California, University of Santa Clara, and Stanford University was held on the Stanford campus April 17, 1931; attendance 165.

In the afternoon visits to engineering laboratories and shops were concluded by a demonstration of high-voltage flashover at the Ryan High-Voltage Laboratory.

During the dinner held in Stanford Union, entertainment was furnished by the Branches; an address of welcome was given by Theodore J. Hoover, dean of the School of Engineering, and Dr. Harris J. Ryan (F '23) executive head of the department of electrical engineering and past-president of the A. I. E. E., spoke on the establishment of the student Branches of the Institute.

The evening's technical program presented by students was as follows:

Vacuum-Tube Voltage Regulators, by Edwin W. Palmrose, senior, University of California.

Development of Television, by Charles Harvey and Lionel Thorpe, juniors, University of Santa Clara.

Corona and Transmission-Line Surges, by Hugh H. Skilling, graduate student, Stanford University.

The prize of one year's Associate's dues in the Institute was awarded to H. H. Skilling.

Past Section Meetings

Baltimore

The Holtwood Hydraulic Laboratory and Its Contribution to the Design of the Safe Harbor Development, by G. W. Spaulding, Pennsylvania Water and Power Co.;

Construction of the Safe Harbor Development, by C. W. Black, The Arundel Corp. Inspection trip to the Safe Harbor Hydroelectric Project. Joint meeting with the Engineering Societies of Baltimore. April 23. Attendance 300.

Birmingham

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of

Virginia, and vice-president, District No. 4, A. I. E. E. March 20. Attendance 7.

Boston

Performance of High-Tension Cable, by F. Malcolm Farmer, Electrical Testing Laboratories. Buffet supper served prior to the meeting. April 24. Attendance 100.

Cleveland

Human Relations in Industry, by Whiting Williams. E. C. Stone, The Philadelphia Co., and vice-president, District No. 2, A. I. E. E. gave a short talk on Institute activities. Two papers were presented by students as follows:

The Cathode-Ray Oscillograph, by J. F. Matyas;

Bridge-Circuit Control of Thyratron Tubes, by I. J. Rand. Joint meeting with the Case School of Applied Science Branch. April 15. Attendance 101.

Columbus

Audible Light and Visible Sound, by John B. Taylor, General Electric Co. Demonstrations. March 27. Attendance 250.

Connecticut

Talks on electrical control of temperature by O. H. Hunt, T. F. Herring, J. J. Carney, and P. A. Borden, all of the Bristol Company's engineering staff. April 14. Attendance 50.

Dallas

Modern Developments in Communications, by S. P. Grace, assistant vice-president, Bell Telephone Laboratories, Inc. Illustrated. Joint meeting with the Dallas Electric Club. April 13. Attendance 340.

Denver

Annual College Night at which the following papers were presented by students:

New Ideas for High-Voltage Circuit Breakers, by Charles A. Church and Neil R. Damon, University of Colorado;

The Life of Faraday, by Oscar Bear, Colorado Agricultural College;

Variation with Temperature of the Magnetic Properties of Iron and Nickel, by Harry H. Ward and Gerald O. Cannon, University of Denver. April 24. Attendance 110.

Detroit-Ann Arbor

The 1,000-Deg. Turbine, by Paul W. Thompson, Detroit Edison Co. There was an inspection of the new Delray Power House and the 1,000-deg. turbine. April 21. Attendance 250.

Erie

Hoboken Electrification of D. L. & W. Railroad, by Edward L. Moreland, Jackson & Moreland. Dinner preceded the meeting. April 21. Attendance 150.

Fort Wayne

Saturated Reactor and Capacitor Circuits, by C. M. Summers and L. F. Hemphill, both of the General Electric Co. April 16. Attendance 60.

Indianapolis-Lafayette

Research and Industry, by E. L. Manning, General Electric Co. Demonstration of the thyratron tube. April 10. Attendance 280.

Iowa

Trend in the Design of Principal Electrical Features of Steam Power Stations, Substations, and Transmission Lines, by H. W. Eales, Byllesby Engineering and Management Corp. Illustrated with lantern slides. April 16. Attendance 35.

Ithaca

Some Recent Developments in Radio Receiver Tubes, by Walter R. Jones, Sylvania Products Co. March 20. Attendance 50.

Lehigh Valley

The Home Lighting Story, by Lilliam E. Eddy, Edison Lamp Works;

When Electricity is the Master Servant, by Clara Zillessen, Philadelphia Electric Co. Illustrated. Ladies' Night held at the Hotel Americus, Allentown, Pa.

Los Angeles

Discussion and demonstration of sound-recording and reproduction as practised in the motion picture industry. Speakers: R. H. Townsend, RCA Photophone Company, H. C. Silent and J. H. Frayne, Electrical Research Products, Inc. Illustrated by lantern slides and talking motion pictures. April 14. Attendance 426.

Louisville

Inspection trip through the Axton-Fisher Tobacco Co. May 8. Attendance 55.

Lynn

Changing Views of the Nature of Matter, by Saul Dushman, General Electric Co. March 18. Attendance 450.

The twentieth annual banquet. March 28. Attendance 460.

Discussion on Radio Tubes, by O. H. Biggs, A. C. Rockwood, G. D. O'Neil, all of the Hygrade Lamp Co. April 8. Attendance 300.

Madison

Modern Electroplating, by J. G. Zimmerman, Burgess Laboratories;

Chromium Plating—The Electroplate that is Different, by Professor O. P. Watts, University of Wisconsin. Inspection trip to the Scanlan-Morris Company's plant. April 29. Attendance 27.

Mexico

Ericssen System of Long-Distance Telephony, by Helge F. Rest, Ericssen Company. April 14. Attendance 22.

Minnesota

Factors Affecting Noise Induction Between Power and Telephone Circuits, by F. R. Kappel, Northwestern Bell Telephone Co. April 29. Attendance 150.

Niagara Frontier

Art in Industry, by D. R. Dohner, Westinghouse Elec. & Mfg. Co.;

Quick-Trip Graphic Meters and Their Application, by D. J. Angus, Esterline-Angus Co. Illustrated. Election of officers as follows: R. W. Graham, chairman; E. S. Bundy, vice-chairman; G. W. Eighmy, secretary-treasurer, H. B. Vidal and G. W. Brooks, members executive committee. April 17. Attendance 50.

Oklahoma City

Telegraphic Pilot-Wire Relay System, by J. D. Browder, Oklahoma Gas & Electric Co. and E. B. Jennings, Southwestern Bell Telephone Co. April 29. Attendance 61.

Pittsburgh

Electric-Arc Furnace Installations, by Samuel Arnold, American Bridge Co.;

Arc-Furnace Control, by C. C. Levy, Westinghouse Elec. & Mfg. Co. Illustrated with lantern slides. Joint meeting with the Engineers' Society of Western Pennsylvania. April 14. Attendance 93.

Philadelphia

Speed, Unemployment, and Progress, by William McClellan, Stone & Webster Engg. Corp. April 13. Attendance 150.

Portland

Application of Vacuum Tubes, by A. W. Copley, Westinghouse Elec. & Mfg. Co. Demonstrated. Joint meeting with the N. E. L. A. March 16. Attendance 96.

Waves or Particles, by A. A. Knowlton, Reed College. Joint meeting with the N. E. L. A. April 21. Attendance 90.

Providence

Magic Tubes, by Prof. F. N. Tompkins, Brown University. Dinner in honor of the speaker preceded the meeting. March 10. Attendance 220.

Rochester

New Developments in Vacuum Tubes, by Eugene W. Ritter, RCA Radiotron Co. Joint meeting with the I. R. E. April 16. Attendance 97.

In Years to Come, by James G. Harbord, Radio Corporation of America. Tenth annual dinner of the engineering societies of Rochester. April 18, Attendance 395.

St. Louis

Introduction of Higher Speed into Transmission Line Protection, by W. E. Winterhalter, General Electric Co. Election of officers for term 1931-32 as follows: C. H. Kraft, chairman; F. B. Wipperman, vice-chairman; C. H. Lankford, secretary. April 15. Attendance 60.

San Antonio

Lightning and Lightning Protection, by P. F. Squier, Westinghouse Elec. & Mfg. Co. Illustrated. April 13. Attendance 32.

Sharon

Hon. Frank Crowther, U. S. Congressman from New York, discussed the problems presented to the last Congress. Before the meeting there was an inspection trip through the McDonald Plant of the Carnegie Steel Co. Joint meeting with the Association of Iron and Steel Electrical Engineers. April 15. Attendance 310.

The Contribution of Telephone Research to Talking Motion Pictures, by J. O. Perrine, American Telephone & Telegraph Co. Illustrated. May 5. Attendance 240.

Spokane

A Progress Report on a Short Circuit Model of the Washington Water Power Company System, by Clarence L. Holmes, State College of Washington;

Short-Circuit Transients In Synchronous Generators, by Robert Pennoyer, University of Idaho;

Fundamentals of Carrier Telephony, by Loren A. Traub, Home Telephone & Telegraph Co. Dinner preceded the meeting. April 24. Attendance 46.

Springfield

Grounding the Neutral, by W. W. Lewis, General Electric Co. Illustrated. March 19. Attendance 56.

Electrotherapy, by William Bierman, president, N. Y. Physical Therapy Society. April 13. Attendance 52.

Toledo

System Regulation, by T. J. Nolan, Toledo Edison Co.;

Storage Batteries, by W. E. Dunn, Electric Storage Battery Co. Illustrated. April 17. Attendance 45.

Toronto

Interesting Developments and Problems in Central Station Engineering, by R. E. Powers, Westinghouse Elec. & Mfg. Co. Joint meeting with Engineering Institute of Canada. April 24. Attendance 250.

Annual meeting. French Faience, by C. H. Mitchell, University of Toronto. Illustrated. Election of officers as follows: T. W. Eadie, chairman; G. D. Floyd, secretary. May 1. Attendance 43.

Utah

Miracles from the House of Magic, by H. T. Plumb, General Electric Co. Inspection of the laboratories at University of Utah followed by dinner. April 9. Attendance 470.

Vancouver

Starting Conditions in Synchronous Machines and an Analysis of the Synchronous-Induction Motor, by H. Vickers, University of British Columbia. April 6. Attendance 33.

Inspection of Ruskin Hydroelectric Development of the British Columbia Electric Railway Co. April 25. Attendance 64.

General Developments in the Bell Telephone Laboratories, by C. C. Pettet, Northern Electric Co. May 4. Attendance 41.

Washington

Lightning and Lightning Arresters, by M. G. Lloyd, Bureau of Standards. Orville S. Peters was presented with the John Scott Award for the invention and development of the electric telemeter. April 14. Attendance 94.

Worcester

Copper from Mine to Consumer, by William H. Bassett, Jr., Anaconda Wire & Cable Co. Joint meeting with the A. S. M. E.

Fused Quartz, by A. L. Ellis, General Electric Co. May 12. Attendance 40.

Past Branch Meetings

Alabama Polytechnic Institute

Election of officers as follows: W. H. Mimns, chairman; T. N. Pyke, vice-chairman; G. F. Fuker, secretary. April 23. Attendance 17.

University of Alabama

Business meeting. April 27. Attendance 15.

University of Arizona

X-Rays and Their Application, by Paul F. Hawley, student. April 10. Attendance 6.

University of Arkansas

Demonstration of a color organ was given by Professor Wesley Roberds, Physics Dept. April 23. Attendance 22.

Armour Institute of Technology

Film—"The Single Ridge." May 1. Attendance 51.

Polytechnic Institute of Brooklyn

Electrons and Sub-Electrons, by Dr. Ernst Weber. April 23. Attendance 42

California Institute of Technology

Power Systems of Germany, England, and France, by Professor W. T. Ryan, University of Minnesota. April 16. Attendance 35.

University of California

Russian Five Year Plan, by Robert Sibley, University of California Alumni Association. Joint meeting with the A. S. M. E. Branch. April 8. Attendance 55.

Carnegie Institute of Technology

Sound Motion Pictures, by Carl Long, student;

Underground Cables, by Thomas Zima, student. Election of officers as follows: Walter B. Wigton, chairman; H. A. Wagner, vice-chairman; F. A. Lennberg, secretary; S. J. Myers, treasurer. April 15. Attendance 22.

University of Cincinnati

Life of Joseph Henry, by D. Michael, student. Illustrated lecture on Electric Ship Propulsion. Election of officers as follows: W. Kock, chairman; H. Koerber, vice-chairman; Mr. Schmidt, secretary; Mr. Manning, treasurer. April 21. Attendance 23.

Clarkson College of Technology

Inspection trip to the sawmill of the Elliott Hardwood Co., Inc., at Potsdam. April 8. Attendance 12.

Colorado State Agricultural College

Inspection trip to the Valmont electrical plant of the Public Service Co. of Colorado. April 24. Attendance 11.

University of Colorado

New Developments in Engineering, by Wm. Trudgian, Westinghouse Electric & Mfg. Co. Film—"Westinghouse Steam Turbines." April 1. Attendance 38.

Annual College Night held jointly with the Denver Section. (For complete report see "Past Section Meetings.")

Cornell University

Talks on the life of Faraday by four students. Election of officers as follows: Randall A. Smith, chairman; Wm. S. Bachman, secretary-treasurer. April 22. Attendance 23.

Drexel Institute

Potentiometer Pyrometer, by Fred C. Haish, student. April 21. Attendance 34.

An explanation and description of the Reading R. R. suburban electrification and Wayne Junction substation construction was given by S. I. Croney, student. May 5. Attendance 10.

Duke University

Courier Systems Used in Telephone Communications of Power Companies, by S. G. Flack, student. Election of officers as follows: S. G. Flack, chairman; A. L. de Bruyne, vice-chairman; J. A. Womack, secretary-treasurer. May 5. Attendance 15.

Georgia School of Technology

Lighting, by Mr. Horton, General Electric Co. April 8. Attendance 113.

Harvard University

Engineering Students and the Management of Men, by Professor E. D. Smith, Yale University. April 24. Attendance 30.

University of Iowa

Four reels of motion pictures on telephone communications were shown. April 15. Attendance 42.

University of Florida

Lighting Design, by John W. Wilson, student. April 13. Attendance 23.

Election of officers as follows: R. E. Walker, chairman; J. C. Huffer, vice-chairman; L. P. Barnett, secretary-treasurer. April 20. Attendance 21.

Kansas State College

The Successful Engineer, by Professor L. M. Jorgenson. April 9. Attendance 67.

The same program was presented at the evening meeting. April 9. Attendance 41.

The Engineering Field, by H. S. Kilby, Kansas Power Co. Film—"The Benefactor." April 23. Attendance 40.

The same program was presented at the evening meeting. April 23. Attendance 70.

The Design of Telephone Outside Plants, by E. C. Kuhlman, Southwestern Bell Telephone Co. May 7. Attendance 73.

The same program was presented at the evening meeting. May 7. Attendance 40.

University of Kansas

Banquet. Attendance 146.

Life of Michael Faraday, by Charles Brecheisen, student;

Life of Joseph Henry, by Clifford Hamel, student. The Branch was presented with the Sigma Tau cup for the best exhibits in the engineering exposition. May 7. Attendance 47.

Lafayette College

Business meeting. May 2. Attendance 25.

Lewis Institute

Description of the electrification of the suburban division of the Illinois Central Railroad Co., by C. H. Mottier, of that company. April 3. Attendance 151.

University of Louisville

Life of Joseph Henry, by Mr. Friedman, student;

Life of Faraday, by Mr. Knoop, student. Mr. Cook, student, reviewed the achievements of 1930. March 20. Attendance 15.

University of Maine

Radio, by Walter J. Creamer, student. April 9. Attendance 22.

Election of officers as follows: R. E. Young, chairman; Gerald Frost, vice-chairman; Roland J. Tibbetts, secretary; Thomas Morrison, treasurer. April 21. Attendance 16.

Vacuum Tubes and Their Industrial Applications, by Oliver Ajer, General Electric Co. Demonstration of the operation of the photoelectric cell and the thyratron. April 23. Attendance 160.

Marquette University

Executive board meeting. March 26. Attendance 7.

Switches and Switching, by J. D. Greensward, Allis-Chalmers Co.;

Personality in Engineering, by H. S. Day, Wisconsin Telephone Co. Annual banquet. April 9. Attendance 50.

Massachusetts Institute of Technology

The PiezoElectric Oscillator in the Power Industry, by B. H. Buckingham; student;

Radio in Aeronautics, by J. G. Ritchey, student. April 14. Attendance 50.

Michigan College of Mining and Technology

Faraday and His Early Experiments, by Oscar Hane, student;

The Early History of Electricity, by William Keyes, student. March 25. Attendance 15.

Michigan State College

Demonstration and explanation of the control device called the "Telemat," by W. H. Bliss, instructor. April 14. Attendance 23.

Talks on the life and work of Faraday and Henry, by E. Moore and J. Young, students. Election of officers as follows: Edwin W. Moore, chairman; John Young, vice-chairman; Webster Bowler, secretary-treasurer. April 28. Attendance 24.

University of Michigan

Experiences with the Detroit Edison Co., by William S. Thomas, student. April 29. Attendance 28.

School of Engineering of Milwaukee

Substations and Substation Metering Equipment, by William Duhn, instructor;

Vacuum Tubes and Their Use in Medicine, by Wm. P. Gainer, Branch chairman. Film—"The Single Ridge." April 8. Attendance 45.

Missouri School of Mines and Metallurgy

The Application of the Photoelectric Cell, by M. R. James, student;

Hydroelectric Developments, by Professor I. H. Lovett, counselor. April 15. Attendance 24.

Inspection trip to the Bagnell Dam. April 18. Attendance 43.

Six films shown as follows: "Telephoto Equipment," "Television," "Electric Heat in Industry," "Induction Voltage Regulators," "Oil Circuit Breakers," and "The Automatic Substation." April 22. Attendance 24.

Montana State College

Banquet given in honor of Dean H. V. Carpenter, University of Washington, and vice-president, District No. 9, at which he delivered an address entitled Continuity of Service. April 9. Attendance 39.

Man and His Machines, by Dean H. V. Carpenter. April 9. Attendance 164.

Electric Communication and the New York Stock Exchange, taken from Electrical Engineering, presented by C. G. Anderson, student;

Cracking Oil by Electricity, taken from Electrical Engineering, presented by Eric N. Blannin, student;

Inspection of Arc Welds, by Edgar Dolum, student;

Two Elevators in One Shaft, taken from *Electric Journal*, presented by Leonard Estey, student. April 16. Attendance 125.

Election of officers as follows: Homer Lambdin, chairman; Jean Smith, vice-chairman; Wesley Funk, secretary; William Scheele, treasurer. April 21. Attendance 30.

Private-Wire Telegraph Service, taken from Electrical Engineering, presented by James Graybeal, student;

Maintenance of Distribution Systems, by Arthur W. Buckley, student;

Railroads vs. Transmission Lines, taken from Electrical Engineering, presented by W sley Funk. April 23. Attendance 120.

Ventilating Electrical Galleries, taken from *Electrical World*, presented by Curtis Hanson, student;

Recent Uses and Developments of Electricity in Transportation, by Armin J. Hill, student;

Radio Beacon Guides Planes, by Homer Lambdin, student. April 30. Attendance 114.

Inspection trip to the Anaconda Copper Mining Company; Morony, Volta, Rainbow, and Black Eagle power plants of the Montana Power Co.; Claude Neon Sign Works; Automatic telephone exchange of the Mountain States Tel. & Tel. Co.; and radio station KFBB. May 4-6. Attendance 29.

Analysis of Radio Interference, by W. H. Bato, student;

Treating Rewound Motors, by Carl Wall, student;

Current Collection in Hydrogen Atmosphere, by Jean Smith, student. May 6. Attendance 77.

University of Nevada

Engineering Economics, by J. Hough, student;

New Developments in Synchronous Motors, by Clarence Jones, student. April 4. Attendance 13.

The Use of Hydrogen in Rotating Electrical Apparatus as a Cooling Medium, by E. H. Tucker, student. April 15. Attendance 24.

Newark College of Engineering

Mercury Arc Rectification, by Paul Dumont, General Electric Co. Election of officers as follows: E. Olsta, president; J. G. Woehling, vice-president; M. Barker, treasurer. April 20. Attendance 25.

University of New Hampshire

The Problems of Telephone Transmission, by O. W. Eshbach, American Tel. & Tel. Co. April 10. Attendance 103.

Vacuum Tubes, by Oliver Ajer, General Electric Co. Demonstrations. April 21. Attendance 83.

College of the City of New York

Eighth annual dinner. April 9. Attendance 112.

Electric Drive of Ships, by Frank V. Smith, General Electric Co. April 16. Attendance 20.

North Carolina State College

Election of officers as follows: G. E. Ritchie, chairman; J. W. Southerland, vice-chairman; L. C. Hubbard, secretary. April 14. Attendance 28.

Radio Frequency Amplifiers, by W. S. Smith, student. May 12. Attendance 21.

University f North Carolina

Radio Applications, by R. V. Whitener, student. Election of officers as follows: D. J. Thurston, Jr., chairman; R. C. Cadmus, vice-chairman; Lloyd Swain, treasurer; Sam Barham, secretary. April 23. Attendance 41.

North Dakota State College

Election of officers as follows: Clarence Bryant, chairman; Fred Payne, vice-chairman; Ralph Simenson, secretary-treasurer. April 13. Attendance 13.

Life of Steinmetz, by Andrew Fritch, student. Film—"Electric Welding." Joint meeting with A. S. M. E. April 16. Attendance 66.

Film—"Dynamic America." Joint meeting with A. S. M. E. and College Engineers' Club. April 30. Attendance 57.

University of North Dakota

Film—"The General Electric Test Course." April 29. Attendance 15.

University of Notre Dame

Substation Design, by E. P. Kreimer, Indiana Michigan Electric Co. Patrick Murray, student, presented the regular engineering news review. April 13. Attendance 46.

Application of Electricity to Metallurgy, by Edward G. Mahin, chemistry dept.;

The Mechanical Larynx, by Charles Podlaski, student. Patrick Murray, student, presented the engineering news review. Election of officers as follows: Hugh Ball, chairman; J. Andres, vice-chairman; F. A. Consolati, secretary; L. R. Rohlof, treasurer. April 27. Attendance 56.

Oklahoma A. & M. College

Power Distribution in City Limits, by V. A. Pendelton, Oklahoma Gas & Electric Co. Election of officers as follows: Joe Hutchinson, chairman; L. C. Hanan, vice-chairman; Clyde Benson, secretary. April 24. Attendance 40.

Oregon State College

Engineering Practise, by E. D. Searing, Portland General Electric Co. April 30. Attendance 33.

Pennsylvania State College

College Illumination, by Professor D. L. Markle. April 22. Attendance 14.

Pratt Institute

Films—"Conowingo" and "Steam Turbine with a Solid Rotor." April 15. Attendance 23.

Mr. Muldaur, National Fire Underwriters' Laboratories, spoke on the testing and setting of standards for mechanical and electrical equipment, and also gave a brief outline of the development of the association and its uses to the public April 23. Attendance 150.

Purdue University

History of Michael Faraday's Life, by M. F. Droege, student;

Experiments by Michael Faraday, by Paul E. Duff, student. W. P. Hallstein and C. C. Fisher, students, gave a demonstration on the operation of a tesla coil. April 28. Attendance 100.

Rhode Island State College

Election of officers as follows: Leon C. Breault, chairman; Byron A. Porter, vice-chairman; Lloyd E. Crandall, Secretary-Treasurer. April 15. Attendance 15.

Rice Institute

Television, by Mr. Kennedy, student. April 15. Attendance 20.

University of Santa Clara

Election of officers as follows: Lionel W. Thorpe, chairman; John Pocharich, vice-chairman; Thomas Eberhard, secretary-treasurer. April 30. Attendance 21.

University of South Carolina

Business meeting. April 13. Attendance 13.

The Engineer and His Connection with Sanitation, by Col. A. E. Legare, supervisor, Dept. of Health. April 20. Attendance 31.

Michael Faraday, by L. E. Rankin, student;

Charles P. Steinmetz, by C. Urquhart, student. April 27. Attendance 35.

South Dakota State School of Mines

Professor J. O. Kammerman, counselor, Almon Bjerke, Branch secretary, and Charles Laws, Branch chairman, gave reports of the fifth annual conference of student Branches of District No. 6. April 22. Attendance 36.

Stevens Institute of Technology

Submarines, by R. C. Welles, student. April 16. Attendance 25.

Syracuse University

Busbar Stresses, by Oliver Bigsby and Edwin Hinchliffe, students;

Scott Connection for Autotransformers, by Lyndon Depew and W. Kleppinger, students. April 17. Attendance 25.

University of Texas

Inspection of the electrical equipment of the Norwood Building, Littlefield

Building, and Austin Power Plant. April 9. Attendance 18.

University of Utah

Election of officers as follows: Richard C. Hansen, chairman; Philip J. Elsey, vice-chairman; W. S. Nishiyama, secretary-treasurer. April 21. Attendance 37.

University of Vermont

Hydrogen Cooling of Rotating Electrical Machinery, by E. J. Mercier, student. April 14. Attendance 22.

Films—"A Concrete Example," "The Telephone Repeater," "Something About Switchboards," and "The World's Telephone Workshop." April 21. Attendance 40.

Election of officers as follows: Donald E. Child, chairman; C. B. Cross, vice-chairman; Robert A. Hyde, secretary-treasurer. April 28. Attendance 24.

Virginia Military Institute

Television, by R. P. Sledge, student;

A Floating Power Plant, by J. C. Shell, student;

Future of Electricity, by H. J. Geiger, student. April 18. Attendance 50.

Virginia Polytechnic Institute

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and vice-president, District No. 4, A. I. E. E. May 5. Attendance 51.

University of Virginia

The History and Development of the Telephone, by B. G. Switzer, student. April 7. Attendance 17.

University of Washington

Television, by Carl Johnson, student. April 9. Attendance 13.

"Ruby" the Next Development of the Skagit, by J. D. Ross, former Superintendent of Lighting, City of Seattle. April 16. Attendance 213.

Washington State College

Direct Coupled Amplifiers, Their Construction and Use, by L. N. Hatfield, Branch chairman. May 1. Attendance 22.

Washington University

Election of officers as follows: D. A. Fischer, president; Charles L. Cline, vice-president; Ernest A. Wolff, secretary-treasurer. April 30. Attendance 16.

West Virginia University

The following talks given by students were based on a recent inspection trip:

Westinghouse High Voltage Laboratory, by H. O. Webb;

H. J. Heinz Co., by J. R. Nottingham;

American Bridge Co., by J. E. Newcomer;

Motors for the P. R. R. Electrification, by C. Malone;

New Power Plant in South Carolina, by H. V. Locker;

Pittsburgh Transformer Works, by F. E. Watson. April 21. Attendance 32.

The following talks given by students were based on a recent inspection trip:

Jones & Laughlin Steel Corp., by G. Pride;

Mesta Machine Co., by S. Boone;

Electrical Communication in N. Y. Stock Exchange, by C. DeLancy;

Synchronous Motors for Ship Propulsion, by P. Steenbergen;

Propeller Type of Pumps, by C. Withers;

Bell Telephone Co., by A. Fervier;

Electrification of the Pennsylvania R. R., by W. Unger;

Eddy Currents, by G. Lefevre. April 28. Attendance 32.

University of Wyoming

Election of officers as follows: Neil Sanders, chairman; T. Hance, vice-chairman; Roy Perkins, secretary-treasurer. April 7. Attendance 10.

Life of Faraday, and Circuit Breakers, by Reece Achenbach, student. May 5. Attendance 8.

Yale University

Election of officers as follows: Ludwig B. Hansen, chairman; J. A. Keyser, sreasurer; F. M. Wolff, secretary. May 1. Attendance 16.

Employment Notes

Of the Engineering Societies Employment Service

Positions Open

ELECTRICAL ENGINEER with experience in designing a-c. and d-c. machines. Apply by letter giving qualifications. Location, vicinity of New York City. W-2753.

YOUNG MAN with training and experience in patent and trade mark law, who would like to work himself into the patent and trade mark problems of a large chemical firm. Apply only by letter. Location, New York. W-2018.

Men Available

ELECTRICAL ENGINEER with 15 years' experience in design, construction, reports and editorial work. Now engaged on special publishing job; will be available for publicity or editorial work on trade publications. References from leading engineering and publishing firms. B-4022.

1930 TECHNICAL GRADUATE, B. S. in M. E., age 24, single. Five and a half months' experience with conveyer manufacturer. Desires training with some engineering company. Salary secondary. Location, immaterial. Available at once. C-9095.

GRADUATE ELECTRICAL ENGINEER, 35, married. Twelve years' experience of which five as junior executive. Desires position as assistant general executive or in transmission or distribution department, United States. Street railway, power and light utility experience. Good references. Available July. C-5091.

ELECTRICAL ENGINEER, age 31, B. S. in E. E. Two years' electric car-shop experience; one year student engineer with power company; two years in engineering department of street railway company; one year electrical control of armament on aeroplanes; one year hydroelectric power studies. C-6077.

COMMUNICATION ENGINEER, 40, married, B. S., E. E. and E. E. degrees. Retired officer naval service. Twelve years' experience administration of communication organizations, development and operation radio-communication systems. Wide experience handling personnel. Three years director of radio, foreign government. Previous experience naval operator. Location, immaterial. Available July 1, 1931. C-9200.

ELECTRICAL ENGINEER, 34, married, graduated in Europe, with nine years' American experience covering drafting, testing, research, supervision of electrolysis work, operating and planning. Familiar with overhead and underground transmission and heavy electrical traction. Last two years as assistant electrical engineer with large hydro projects. Available on short notice. C-9170.

GRADUATE ELECTRICAL ENGINEER, desires substantial connection with public utility or industrial firm on power engineering as engineer or assistant to superintendent or engineer. Ten years' experience in power-plant test, operation, design, construction, and maintenance. Three years electrical engineer for industrial firm. Two years assistant to power engineer. B-8379.

ELECTRICAL ENGINEER, 35, married, B. S. in E. E., four years' experience in electrical design at steam and hydroelectric plants, switching stations, substations and transmission lines including field experience; two years design and construction of railway electrification. Also has had practical experience in industrial construction, factory and steel mill maintenance. References. C-9211.

SALES EXECUTIVE ENGINEER, electrical training and seven years' experience covering sales engineering, sales promotion, sales management. Has traveled extensively, acquainted with conditions in all sections of country. Well acquainted with New England. C-5431.

ELECTRICAL DESIGNER, age 36, married. Ten years' public utility experience in steam and hydroelectric plants, substations and industrial plants. Also served four years as fire insurance inspector. Graduate of technical school on electrical and mechanical subjects. C-7979.

ELECTRICAL ENGINEER, graduate, E. E. degree 1930, 25, American, single. Experience power-cable research and testing and allied work. Desires any kind of work in electrical engineering field. Best references. Available immediately. Any location considered. C-9188.

1930 GRADUATE OF E. E. under the cooperative plan at Georgia Tech. Worked alternate months with public utility company in Georgia in car-barn, gas, engineering, hydro-generation and statistics departments. Since graduation has worked six months with transmission line construction crew. Any location. C-9210.

ELECTRICAL ENGINEER, 30, married, university graduate, two years' experience distribution engineering for large electrical manufacturer; six years' experience power-plant and substation maintenance, operation, design, and construction with large power company. Wants position with power company, engineering, or construction firm. Available upon short notice. Will go anywhere. C-9267.

RADIO ENGINEER, 33, broad training in research, development and production of radio receivers, accessories, and component parts; responsible charge of quality; commercial understanding of engineering relations to purchasing and manufacturing; advertising and sales experience; resourceful. Available to progressive organization in radio or allied fields. B-5752.

EXPERIENCED TRANSLATOR, ELECTRICAL ENGINEER by profession, French and German, would prefer to translate technical and scientific books. Best of references. B-7091.

GRADUATE ELECTRICAL ENGINEER, 1930, 24, single. Seven months' experience transmission-line construction. Excellent physical condition. Desires position with future. Location preferred, East. C-9238.

ELECTRICAL ENGINEER, college graduate, over 20 years' experience in high-voltage transmission line and power-station work, principally with Siemens Schuckert and Brown Boveri companies in Germany. Desires responsible position. C-9257.

ELECTRICAL ENGINEER, 31, single, graduate University of California (1927), varied experience, designing, developing, testing high-frequency measuring apparatus. Has had some work engineering department, electrical manufacturing and radio concern. Desires connection with public utility, industrial equipment company. Now employed on development high-frequency apparatus. Location preferred, New York City. C-6734.

ENGINEER, college graduate with B. S. in E. E., seeks connection as chief engineer or superintendent of industrial plant or office building. Fifteen years' broad experience in power installation, operation and maintenance of electrical, mechanical and steam equipment. Familiar with building operation and maintenance. References furnished with interview. C-9262.

SWITCHBOARD FOREMAN, ten years' experience with construction companies for public utilities, wiring, construction and installation of powerhouse switchboards and control apparatus. Shop experience, manufacturing switchboards. C-4831.

SENIOR STUDENT in electrical engineering, graduating in June from Colorado University, available July first. Desires position as a junior engineer, sales engineer or instructor in mathematics or electrical engineering subjects. Has had 18 months' practical work in electrical service and repair of power equipment prior to college. Location preferred, Southern or Western United States. C-9241.

ENGINEER, graduate Stevens, one and one-half years' G. E. Test, with broad knowledge of transmission operation gained during five years with public utility operating in the foreign field; seeks new connection either domestic or foreign. Would be valuable for staff of general superintendent; mechanical engineer with electrical experience. C-9177.

GRADUATE ELECTRICAL ENGINEER, 1929, age 24, single. Two years' experience in overhead distribution and transmission design, drafting, and estimating. Best of references. C-9256.

ELECTRICAL AND RADIO ENGINEER, 39, University graduate with B. S. in E. E. G. E. Test experience. Fifteen years in design, test and operation of radio and high-frequency circuits and apparatus. Married, two children. Location secondary importance, West preferred. Available immediately. C-9246-314-C-12-San Francisco.

GRADUATE ELECTRICAL ENGINEER, age 25. Two years' experience in power system operation, system planning and development; also experience in distribution and transmission engineering. Desires position in any location with public utility, or in any electrical line offering a future. Available upon short notice. References. C-9281.

RADIO ENGINEER, 35, married, A. B. in M. E., and Engineer in E. E. Fourteen years' experience, research, development, design, installation, and testing of radio transmitting equipment. Also experienced, patent investigations, office management, and purchasing of materials. Desires executive, research, or teaching position permitting advancement of art of radio communication. C-9251.

ELECTRICAL, MECHANICAL, CONSTRUCTION ENGINEER, 35, married. Experience in installation of automatic equipment in power stations, general construction about 11 years. Has five years air-corps service. Available upon notification. Location preferred, San Francisco, California. C-9247-314-C-15-San Francisco.

GRADUATE ELECTRICAL ENGINEER, 23, B. S., M. S. in E. E. Desires position, instructor in engineering department of college, university. Has fundamental, practical knowledge d-c., a-c. circuits and machines. Can teach engineering mathematics, physics. Has had some teaching experience; two years research work obtaining degrees. Available July 1st. Location, anywhere United States. C-9214

GRADUATE ELECTRICAL ENGINEER, 29, one year Westinghouse Test course, six years engineering for large eastern utility. Familiar design, construction, and operation of distribution substations, customers' services, load dispatching and supervisory-control system. Desires responsible position with public utility, consulting engineers, or sales work with electrical manufacturer. C-8322.

RELAY ENGINEER, university graduate, ten years' practical experience, thoroughly familiar with all relay applications and testing, short-circuit studies, stability calculations, and all problems connected with system disturbances. Moderate salary. Available at once. C-9291.

ELECTRICAL ENGINEER, 25, married, desires engineering work. Has been on electrical seismograph for last two years. Work involved use of portable oscillograph and wireless telegraphy. Holds second-grade commercial operator's license. Has one year public utility experience and surveying experience. Personal interview desired. C-3035.

ELECTRICAL ENGINEER, 23, single, graduate Georgia School of Technology, B. S. degree in E. E. Cooperative plan 1930; five years' experience railroad shop all departments during cooperative course; one year experience with utility on manufacturing concern. Prefers Southeast. C-9292.

DISTRIBUTION ENGINEER, 29, single. Six years' experience on overhead distribution, estimating, design, construction and revamp in general office of large utility. Available immediately. Location preferred, West, but will consider others including foreign country. C-9307-314-C-13-San Francisco.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.	205 West Wacker Drive	31 West 39th St.
San Francisco	Chicago	New York
N. D. Cook, Manager	A. K. Krauser, Manager	W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

JUNIOR ENGINEER, 1930, graduate, B. S. degree in E. E. Associate member of Sigma Xi. Eight months' practical experience in research, design, and testing with large radio concern. Desires position as engineering instructor or in any electrical line offering a future. Eastern location preferred. Salary secondary to opportunity. C-9300.

ELECTRICAL ENGINEER, age 28; single; considerable industrial experience; one year as graduate assistant; M. S., Iowa State College, 1930; B. S. Pennsylvania State College, 1925. Desires position as instructor with the prospect of a permanent teaching position. C-3202.

ELECTRICAL ENGINEER, 28, A. B., E. E. 1926. Two years as emergency man, one year as engineering assistant with a New York Power Company. Four years with a Telephone Company making studies of equipment and operating conditions and on service maintenance. Two years teaching mathematics in evening classes. References. C-9308.

HEATING ENGINEER, 12 years' experience, largely on industrial electric heating equipment, particularly heat treating and forging furnaces. University of Wisconsin graduate (1918). Some arc-welding and motor design experience. Familiar with research, design and sales practise. Locate anywhere. Prefer executive position. B-8838.

ELECTRICAL ENGINEER, B. S. degree in E. E. in 1925. Five years' experience in electrical equipment design, public utility operation, and field construction. Natural writing talent. Desire work in editorial or related fields. C-4875.

RADIO ENGINEERING GRADUATE, student in one of the greatest eastern universities, desires connections fitting his education. Has B. E. degree in E. E. and has been very active in radio engineering practise for seven years. Available at once, age 23 years. C-7315.

GRADUATE IN ELECTRICAL ENGINEERING, 1928, married; one year's experience on Westinghouse test floors assigned to traction apparatus. Has completed Westinghouse graduate student course. Has had approximately 18 months' experience as sales engineer. Especially interested in work within transportation industry, or as instructor in recognized engineering school. Excellent scholastic record and references. C-9309.

GRADUATE ELECTRICAL ENGINEER, 35, good technical school. Ten years' experience in electrical station construction and design drafting, including considerable mechanical experience. Latest position superintendent of design and construction of transformer substation. Preferring station design and construction with utility, would consider engineering industrial plant maintenance or operation. C-7043.

COLLEGE GRADUATE class of '29, B. S. degree in electrical engineering, 25, single, G. E. Test, general engineering and business courses. Interested in position in engineering department of manufacturing or utility company. Available at once. Location, Eastern United States. C-9003.

ELECTRICAL-MECHANICAL ENGINEER, 28 years old, experienced in power generation, distribution and application to industrial uses. Desires position as electrical-mechanical engineer in charge of operation, maintenance and repairs with manufacturing concern generating own power. C-9063.

GRADUATE ELECTRICAL ENGINEER with broad experience in development and design, executive and engineering on small electric motors, desires connections as engineer or chief draftsman. Available in from twenty to thirty days. Married. References. B-9395.

COLLEGE GRADUATE, 27, single, B. S. in E. E. Eighteen months General Electric Test, twenty-two months telephone equipment engineer. Desires position in manufacturing or utility company. Location preferred, Middle West, but, not essential. Available at once. C-9285.

ELECTRICAL ENGINEER, B. S. degree 1929, married, 33, American. Two years' experience as a draftsman-designer with large utility company. Experienced on outdoor and indoor high-voltage substations. Speaks Russian, (United States citizen). Well acquainted with Manchuria, China. Location, immaterial. C-6290.

ESTIMATING ENGINEER, B. S. degree in E. E., age 34, married. Ten years' experience with large company manufacturing electrical power equipment, including designing electrical and mechanical construction and calculating cost, weight and dimensions of this apparatus, in connection with customers' negotiations. Available at once. Location, immaterial. C-4633.

GRADUATE ELECTRICAL ENGINEER, single, age 25, eight months engineering assistant power department office of public utility, fourteen months equipment engineer handling installation and testing of toll line telephone equipment. Good general knowledge of building trades. Excellent references. Location, immaterial. C-8126.

ELECTRICAL ENGINEER, 24, single; B. S. in E. E., 1929; M. S. 1931. Westinghouse graduate student course. Some experience in acoustic and radio laboratories. Six months' experience with phototube and grid-glow tube applications. Natural writing ability. Available at once. Location, immaterial. C-9314.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, age 24 and single. Experience in machine shop and steel construction work. Four years of practical and theoretical electricity in college. Willing to start at bottom and work up with a reliable company. Available any time. Location, anywhere in United States. C-9135.

ELECTRICAL ENGINEER, age 45, technical school graduate desires position with railway, consulting engineer, or industrial plant. Twenty-four years' experience with large street railway and electrical contractor on drafting, designing, estimating, construction and operation of power, distribution and miscellaneous electrical. Conversant with power reports, new projects, budgets and executive responsibility. C-7202.

ELECTRICAL ENGINEER, 1930 graduate, 22, single. One year on the Westinghouse student course. Desires position as instructor in electrical engineering. Available school year 1931-1932. References. Location, immaterial. C-9311.

ELECTRICAL ENGINEER, B. S. E. E., '29, M. S. E. E. '31, leading university, 18 months General Electric Test, 23, single. Desires to teach in technical university. Prefer Mid West. C-9320.

ELECTRICAL ENGINEER with Master's degree, industrial design and development of electrical-control equipment, authority on electrolytic condensers; married; will work anywhere except Russia. Available on six weeks' notice. Employed at present. Not interested in position without full responsibility. C-7288.

ELECTRICAL EXECUTIVE, 39, married. Thoroughly experienced in power plant and industrial construction, maintenance. Can handle men and improve service. Very well qualified to assume part of the responsibility of a busy executive. Replies confidential. C-2028.

ELECTRICAL ENGINEER for eight years in charge of design and construction of large switching stations up to 220,000 volts in the East, and with strong mechanical and structural antecedents seeks permanent connection. C-9332.

Membership

Recommended for Transfer

The Institute's board of examiners at its meeting of April 29, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

To Grade of Fellow

KELLY, MERVIN J., Vacuum Tube Development Engr., Bell Telephone Laboratories, Inc., New York.
KRAFT, CHRISTOPHER H., Supt. of Electrical Distribution, Union Electric Light and Power Co., St. Louis, Mo.

To Grade of Member

AJANI, FRANCESCO, vice-director, Societa Industrie Elettrotelefoniche, Turin, Italy.
ALLENDE, OCTAVIO E., asst. general mgr., Compania Electrica de Cartago, Costa Rica, C. A.
CARTER, E. L., consulting engr., 814 Continental Bank Bldg., Indianapolis, Ind.
COOPER ROBERT S., supervisor of communications, West Penn Power Co., Connellsville, Pa.
CORSON, LeROY, supervisor, N. Y. & Queens Elec. Lt. & Pr. Co., Flushing, N. Y.
FEDER, TOBIAS M., district sales mgr., Jeffery Dewitt Insulator Co., Chicago, Ill.
GOLDTHWAITE, GEORGE E., consulting engr., Hine, Goldthwaite & Mylott, New York.
MARQUIS, VERNON M., elec. engr., American Gas & Elec. Co., New York.
MARTIN, EDWIN R., motor engr., Delco Products Corp., Dayton, Ohio.
RALPH, ARTHUR J., technician, Yale University, New Haven, Conn.
ROTTY, OSCAR J., supt. of substations, Union Electric Lt. & Pr. Co., St. Louis, Mo.
SANO, SHIRO, president, Sano Electric Mfg. Co., Tokyo, Japan.
SCHULER, L. R., inspector, Public Service Co. of Northern Illinois, Chicago, Ill.
WRIGHT, SUMNER B., telephone engr., American Tel. & Tel. Co., New York.

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before June 30, 1931.

Atkinson, C. R., General Electric Co., Fort Wayne, Ind.
Bailey, R. S., (Member), American Tel. & Tel. Co., New York, N. Y.
Balzer, E. W., Healds Engineering College, San Francisco, Calif.
Bangs, J. E., (Member), Suite 1122, Earle Bldg., Washington, D. C.
Bardwell, M. W., Syracuse Lighting Co., Inc., Syracuse, N. Y.
Barkson, J. A., American Tel. & Tel. Co., Cleveland, Ohio
Bonnett, A. A., Alaska Gold Mines Co., Thane, Alaska
Boulton, B. K., (Member), Beauharnois Construction, Beauharnois, Que., Can.
Buese, L. A., Los Angeles Gas & Electric Corp., Los Angeles, Calif.
Burleson, W. H., (Member), Ohio Brass Co., Mansfield, Ohio
Campbell, R. W., General Electric Co., New York, N. Y.
Clark, Maurice E., New England Tel. & Tel. Co., Boston, Mass.
Elliott, H. J., Atmospheric Nitrogen Co., Hopewell, Va.
Fouracre, V. W. M., M. Montgomery & Co., Ltd., Vancouver, B. C., Can.
Friedman, V. N., (Member), Jas. R. Kearney Corp., St. Louis, Mo.
Gills, E. T., Ohio Brass Co., Mansfield, Ohio
Gonzalez, J. J., Veracruz Electric Lt. Pr. & Traction Ltd., Veracruz, Mexico
Harris, C. E., Duke Power Co., Charlotte, No. Car.
Hatfield, B. F., Southern Bell Tel. & Tel. Co., Atlanta, Ga.
Herwegh, L. J., (Member), Atwater Kent Mfg. Co., Philadelphia, Pa.
Holmes, L. O., Rensselaer Polytechnic Institute, Troy, N. Y.
Hutson, R. V., Cincinnati & Suburban Bell Tel. Co., Cincinnati, Ohio
Ingles, J. A., Hydro-Electric Power Commission of Ontario, Toronto, Ont., Can.
Jack, F. M., New York Edison Co., New York, N. Y.
Kalen, E. T., N. W. Electric & Machine Co., Milwaukee, Wis.
Kanekeberg, A., Public Service Co. of Colo., Denver, Colo.
Kiltie, O., General Electric Co., Fort Wayne, Ind.
Kimbrell, M. R., (Member), Duke Power Co., Charlotte, No. Car.
Lyons, S. E., D. L. & W. Railroad Co., Hoboken, N. J.
May, D. M., Collins Flashlight Corp., New York, N. Y.
McGuire, F. J., Otis Elevator Co., Yonkers, N. Y.
Morgan, F. D., Allied Engineers, Inc., Jackson, Mich.
Morris, F., Saskatchewan Power Commission, Moose Jaw, Sask., Can.
Muller, H. S., New Jersey Bell Tel. Co., Newark, N. J.
Myers, C. F., Puget Sound Power & Light Co., Wenatchee, Wash.
Needham, G. H., New Jersey Bell Tel. Co., Newark, N. J.
Organ, J. W., Union Electric Light & Power Co., St. Louis, Mo.
Peterson, A. W., Continental Electric Co., Inc., Newark, N. J.
Peterson, N. T., MacMillen Elec. & Mfg. Co., Los Angeles, Calif.
Powell, J. A., (Member), W. S. Barstow & Co., Inc., Reading, Pa.
Rogers, T. A., University of California, Berkeley, Calif.
Russell, H. G., 37 Harvard St., Worcester, Mass.
Slezak, S. T., New York Telephone Co., New York, N. Y.
Warrington, A. R., General Electric Co., Philadelphia, Pa.
44 Domestic

Foreign

Gara, E., Chile Exploration Co., Chuquicamata, Chile, So. America
Hofman, S. P., The General Electric Co., Ltd., Witton, Birmingham, Eng.
Kempe, R., Asea, Ludvika, Sweden
Robinson, C. S., Cia. Chilena de Electricidad Ltd., Santiago, Chile, So. America
Singh, G., Mussoorie Hydro-Electric Scheme, Dehradun, U. P., India
Stock, J. M., Cia. Interprovincial de Servicios Publicos S. A., Buenos Aires, Argentina, So. America
Texier, J., M. M. Schneider & Cie, Paris, France
van Dyk, J., Philips Lamps (A'sia) Ltd., Sydney, N. S. W., Australia

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during April are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

Electrical Drafting and Design. 2nd edit. By C. C. Bishop. N. Y., McGraw-Hill Book Co., 1931. 190 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $2.00.——Covers the ordinary work done in the office of an engineer, contractor or power company, in drafting and designing layouts, switchboards, residence and power wiring, etc. A collection of tables is included. The book bridges the gap between the usual course in mechanical drawing and the practical methods of the industry. The new edition has been revised to meet changes in underwriters' rules and in apparatus.

Grundwasser-Abdichtung. 3. Auflage. By J. Schultze and W. Sichardt. Berlin, W. Ernst u. Sohn, 1931. 69 pp., illus., diagrs., tables, 10 x 7 in., paper. 5-r. m.——A concise review of practical methods for waterproofing mortar and concrete in underground structures. The advantages and disadvantages of different methods are described and directions given for their use.

Grundzüge der Technische Schwingungslehre. By O. Föppl. Berlin, J. Springer, 1931. 212 pp., illus., diagrs., tables, 8 x 5 in., cloth. 9.50-r. m.——2nd edit. A concise treatise on the theory of vibration and its applications in engineering. The effects of vibration upon structural materials, methods of calculating frequencies, damping devices, the prevention of vibration in reciprocating machines, and similar topics are discussed.

High Frequency Alternating Currents. By K. McIlwain and J. G. Brainerd. N. Y., John Wiley & Sons, 1931. 510 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth. $6.00.——A course for senior students, as given at the University of Pennsylvania. The theory of these currents is presented and their use in telephony, radio communication, remote control, and other purposes are discussed.

High-Speed Diesel Engines. By A. H. Goldingham. Lond., E. & F. N. Spon, Ltd., 1931. 148 pp., illus., diagrs., charts, tables, 9 x 6 in., 10s. 6d.——After an introductory chapter upon the theory and advantages of this engine, the various systems of fuel injection are described in detail. The remaining two-thirds of the book describes various types of high-speed Diesel engines. The book summarizes the present position of this engine in convenient form.

"Hütte" des Ingenieurs Taschenbuch. 26 Auflage, 1 Band, 1931. By Akademische Verein Hütte. Berlin, W. Ernst u. Sohn, 1931. 1199 pp., diagrs., charts, tables, 8 x 5 in., cloth, 17,50 r. m.; leather, 20,50 r. m.——The first volume of the new edition covers such fundamental matters as mathematics, mechanics, technical physics, heat, strength of materials, materials, measurements and surveying. Compared with the previous edition, this is ten per cent larger and has been thoroughly revised throughout. Hütte still remains the most comprehensive collection of engineering tables, formulas and general information in print.

Mathematical Tables and Formulas. By R. D. Carmichael and E. R. Smith. Bost. & N. Y., Ginn & Co., 1931. 269 pp., diagrs., tables, 9 x 6 in., cloth. $2.00.——This compilation aims to meet the needs of students in mathematics courses and other courses that require mathematical computations or involve mathematical processes. It contains the usual logarithmic and trigonometric tables, up to five places, needed in the study of college algebra and trigonometry; other numerical tables frequently used in computation; and a collection of mathematical formulas, integrals and series.

Modern Diesel Engine Practice. By O. Adams. N. Y., Norman W. Henley Publ. Co., 1931. 656 pp., illus., diagrs., tables, 10 x 6 in., cloth. $6.00.——A descriptive work, intended primarily for the operating engineer and the owner. Special attention is given to applications of Diesel engines, and to operating and maintenance practise. Aircraft engines and locomotives are included.

Non-Interpolating Logarithms, Cologarithms and Antilogarithms. By Frederick W. Johnson. San Francisco, Simplified Series Publ. Co., 1930. 23 pp., tables, 9 x 6 in., limp cloth, note-book edit. $1.60; fabrikoid, $2.25; full leather, $4.00——Four-place and five-place logarithms and antilogarithms, and four-place cologarithms can be obtained from these tables by inspection, without any calculation. The tables are very compactly printed, in clear type, on substantial paper, and are thumb indexed. Additional tables of constants, metric conversion factors and other frequently used data are included.

Pocket-Book of Electrical Rules and Tables. By W. R. Cooper and R. Appleyard. Phila., J. B. Lippincott, 1931. 765 pp., illus., diagrs., tables, 7 x 4 in., cloth. $4.00.——A reference book giving special attention to electrical instruments and measurements, conductors, submarine cables, telephony and radio, but also treating more briefly of electrometallurgy, dynamos, balancers, transformers, power-factor improvement and illumination. The book has long been valued by cable and telegraph engineers as a practical pocketbook. Various specialists have contributed to the revised edition.

Radio Handbook, including Television and Sound Motion Pictures. By J. A. Moyer and J. F. Wostrel. N. Y., McGraw-Hill Book Co., 1931. 886 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth. $5.00.——A concise but comprehensive reference book for the radio engineer. The authors have summarized the existing data upon radio apparatus, not only for telephony and telegraphy, but also for industrial power control and similar purposes.

Radioelements and Isotopes: Chemical Forces and Optical Properties of Substances. By K. Fajans. N. Y., McGraw-Hill Book Co., 1931. 125 pp., diagrs., charts, tables, 9 x 6 in., cloth. $2.50.——A review of the researches of the author and others upon the nature of chemical forces and the relation of these forces to the optical properties of atomic and crystal structures. The book is based upon the author's lectures at Cornell University during 1930.

S. A. E. Handbook. 1931 edit. Society of Automotive Engineers, N. Y. 752 pp., diagrs., charts, tables, 8 x 4 in., cloth. $5.00 to non-members.——Contains the standards and recommended practises of the Society, revised to March, 1931.

Standard Wiring for Electric Light and Power, 1931. By H. C. Cushing, Jr. Publ. by H. C. Cushing, Jr., N. Y., 1931. 503 pp., illus., diagrs., tables, 7 x 4 in., leather, $3.00.——The new edition of this well-known handbook has been thoroughly revised to represent the latest approved practise. Specific directions are given for wiring for all ordinary purposes, for installing motors, generators and storage batteries, and for lighting.

Vergrösserung der Effektiven Höhe von Flugzeugschleppantennen. (Luftfahrtforschung Bd. 8, s. 141-154, Heft 6, 3 März 1931.) By F. Eisner, G. Sudeck, R. Schröer and O. Zinke. München, R. Oldenbourg, 1931. Illus., diagrs., tables, 12 x 8 in., paper, 2,80 r. m. ——Reports the results of an investigation of the efficiency of trailing antennas for aircraft radio stations and describes an improved L-shaped antenna.

List of Alloys with Physical Properties of Typical Alloys. By W. Campbell. Phila., American Society for Testing Materials, 1930. 65 pp., 9 x 6 in., paper, $1.50; cloth, $2.00. Over 2,500 alloys are represented. These are mostly non-ferrous alloys, but certain non-corrosive and heat-resistant iron alloys are included. The composition of each alloy is given and, in some cases, the physical properties.

Personnel Problems. Methods of Analysis and Control. By F. E. Baridon and E. H. Loomis. N. Y., McGraw-Hill Book Co., 1931. 452 pp., diagrs., charts, tables, 9 x 6 in., cloth. $5.00.——Intended as guide in the study and solution of these problems. The questions that constantly arise under modern industrial conditions are outlined specifically, and methods for their analysis and control are suggested.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

ORDER FORM FOR REPRINTS OF FULL PAPERS ABRIDGED IN THIS ISSUE OF *ELECTRICAL ENGINEERING**

(June 1931) Number	Author	Title
☐ 31-1	William B. Blanton	A Printing Telegraph Concentrator
☐ 31-15	Charles Kerr, Jr	Motive Power for Suburban Electrification
☐ 31-16	Samuel Martin, Jr	Electric Resistance Brazing
☐ 31-31	F. Creedy	The Neutralized Welder—A Means of Controlling Transients
☐ 31-33	C. Richard Soderberg	Heat Losses in Large Turbine-Generators
☐ 31-38	G. M. Little	The Application of the Helical Groove to Slip-Rings and Commutators
☐ 31-48	H. E. Edgerton and Paul Fourmarier	The Pulling Into Step of a Salient-Pole Synchronous Motor
☐ 31-55	R. M. Stanley and C. T. Sinclair	The Primary Network
☐ 31-59	R. D. Evans and S. H. Wright	Power System Voltages and Currents Under Fault Conditions
☐ 31-61	W. A. Lewis and L. S. Tippet	Fundamental Basis for Distance Relaying on Three-Phase Systems
☐ 31-65	R. L. Young and R. L. Lunsford	Automatic Power Plants for Telephone Offices

*Members, Enrolled Students and subscribers are entitled to one complete copy of any paper abridged if it is requested within one year from date of its publication in Electrical Engineering. Thereafter a charge of twenty-five cents per complete copy will obtain.

Selected Items From

Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translation of foreign articles at cost.

Boilers

ELECTRIC. Packed Heat from a New Type of Electric Steam Generator, H. Bidwell and L. H. Jones. *Indus. and Eng. Chem.*, vol. 23, no. 3, Mar. 1931, pp. 298-300, 2 figs. Description of generator suitable for hospital sterilizers, pressure cooking retorts or industrial processes where large amount of steam is required for short time which has reservoir properly located between high- and low-water levels which serves as source of energy, so that pressure from boiler is immediately available when required.

Cables

FAULT LOCATION. Service d'études et de recherches techniques (Study of Underground Conductors and their Failures). *Annales des Postes Télégraphes et Téléphones*, vol. 20, no. 2, Feb. 1931, pp. 153-160, 8 figs. By running telephone frequencies through cable and by using loop operated amplifier, course of cable or of single conductor in group of conductors and various types of faults and insulation troubles can be detected.

HIGH TENSION. Elektrische Arbeitsuebertragung durch Hochspannungskabel (Electric Power Transmission Through High-Voltage Cables), J. Kuehle. *Elektrotechnische Zeit.*, vol. 52, no. 12, Mar. 19, 1931, pp. 373-377, 15 figs. Comparison between operating characteristics of cable and overhead lines; advantages and disadvantages of both systems shown by numerical comparison; three-conductor and single-conductor cables in three-phase system; lead sheath losses and process in dielectrics.

LEAD SHEATHING. Kristallgefuege und Disglomeration des Bleies (Crystaline Structure and Disglomeration of Lead), O. Haehnel. *Elektrische Nachrichten Technik*, vol. 8, no. 2, Feb. 1931, pp. 77-88, 16 figs. Metallographic measurement of crystallite grain of pure lead yield mean diameter of 8 mm. being largest crystallites which ever have been observed in cast lead cooled in manner as described; all lead drawn from cable lead presses has much smaller crystallites; grain in cable press is determined by operating temperature and working pressure.

METAL SHEATHED. De la préférence à donner aux alliages plomb-antimoine, plomb-antimoine cadmium sur le plomb pur dans la fabrication des gaines de cables électriques et téléphoniques (Superiority of Lead-Antimony, Lead-Antimony-Cadmium over Pure Lead in Manufacture of Sheathing for Electric and Telephone Cables), H. Godin. *Revue Universelle des Mines*, vol. 5, no. 4, Feb. 15, 1931, pp. 106-109, 1 fig. Failure of cable sheaths without apparent cause; results of analyses of failure by Archbutt and Radwdon; means of avoiding intercrystalline failures of cable sheaths.

POTHEADS. Die bisherige Entwicklung der Kabelendverschluesse ohne Vergussmasse (Present Development of Cable Potheads Without Dilling Compound), E. Eule. *Siemens Zeit.*, vol. 11, no. 2, Feb. 1931, pp. 95-102, 20 figs. Equipment of Siemens and Schuckert, its features, application and installation are described.

STANDARDS. Standard Color Code for Control Cable, G. Sutherland. *Power Plant Eng.*, vol. 35, no. 7, Apr. 1, 1931, pp. 413-414. Color scheme prepared by joint committee of N.E.L.A. and N.E.M.A. following extensive review of questionnaires sent to 26 leading American utility companies and survey of field tests conducted by joint committee; standard color scheme table for control cable.

TELEPHONE—LIGHTNING. Blitzschlaege in Fernkabelanlagen (Lightning Strokes in Long Distance Telephone Cables), P. Kleinsteuber. *Telegraphen und Fernsprech Technik*, vol. 20, no. 2, Feb. 1931, pp. 48-50, 5 figs. Various typical cases and their analysis.

Circuit Breakers

OIL. New Ironclad Switchgear. *Engineer*, vol. 151, no. 3925, Apr. 3, 1931, p. 386, 2 figs. Following success of "T A P" circuit breaker by Crompton-Parkinson, Ltd., of Chelmsford, firm has designed metal-clad oil circuit breaker on somewhat similar lines; unit is made for currents up to 300 amperes at 3,300 volts, or 600 amperes at 650 volts for three- or four-wire circuits, and can be used singly or number of units can be made to form switchboard.

Circuits

VECTOR ANALYSIS. Mechanical Aids in the Construction of Vector Diagrams, B. S. Willis. *Gen. Elec. Rev.*, vol. 34, no. 4, Apr. 1931, pp. 224-227, 6 figs. Numerical solutions combined with graphical representations; various examples from electric circuit practise are given.

Compensators

Détermination d'un groupe formé par un transformateur à trois enroulements et un compensateur synchrone (Determination of System Formed by Three Winding Transformer and Synchronous Compensator), F. Hallopeau. *Revue Générale de l'Electricité*, vol. 29, no. 9, Feb. 28, 1931, pp. 338-348, 9 figs. Power calculation of compensator connected to network by means of transformer as outlined; mathematical and graphical solution; vector diagrams of transformer.

Condensers

STATIC. Les condensateurs statiques et l'amélioration du facteur de puissance (Static Condensers and Improvements of Power Factor), *Science et Industrie*, vol. 15, no. 205, Feb. 1931, pp. 88-92, 11 figs. Problem; electric rates; determination of corrective capacity in kva. for given installation; various solutions; comparison between condensers and synchronous motors; electric condenser as accepted electric equipment.

TESTING. Bemerkungen zur Pruefung von Kondensator-Durchfuehrungen (Remarks on Testing of Condenser Bushings), L. Kumlik. *Elektrizitaetswirtschaft*, vol. 30, no. 6, Mar. 1931, pp. 171-172. Manufacture is started by other hard paper plants since exhaustion of Nagel patents; as these have no previous experience critical analysis is given of usual testing method from which conclusions may be drawn as to quality of product.

Conduits

UNDERGROUND. Expérience d'un nouveau procédé de construction des conduites multitubularies sans joint (Test of New Process of Construction of Multi-Duct Jointless Conduits), M. Moine and L. Daumard. *Annales des Postes Télégraphes et Téléphones*, vol. 20, no. 3, Mar. 1931, pp. 178-192, 12 figs. Description of Oravetto design, tested in Nice, France; design calls for reinforced-concrete monolith blocks containing as many as 12 parallel circular ducts 10 cm. in diameter.

Contactors

A Periodic Contactor Operated by a Neon-Tube Oscillator, H. J. Reich. *Rev. Sci. Instruments*, vol. 2, no. 3, Mar. 1931, pp. 164-170, 5 figs. Simple device, capable of closing circuit periodically at any desired frequency and holding it close for any desired fraction of cycle, finds frequent use as laboratory or lecture demonstration apparatus; writer had occasion to design such instrument, in which timing device was neon-tube oscillator; reliability and general usefulness of this device during almost year; design and constructional details.

Discharge

ELECTRODELESS. Sur un nouvel aspect de la décharge en haute fréquence (New Phenomenon in Electrodeless Discharge), M. Chenot. *Académie des Sciences—Comptes Rendus*, vol. 192, no. 1, Jan. 5, 1931, pp. 38-40; see also brief translated abstract in *Experimental Wireless*, vol. 8, no. 90, Mar. 1931, p. 166. Experiments in electrodeless discharge obtained with 3.4-m. waves led to appearance of series of stationary waves which indicate wave propagation along tube at velocity between 3 and 5 per cent of velocity of light; author had previously suggested that long-delay radio echoes may be due to such propagation at greatly reduced velocities.

Education

ENGINEERING. Report of 1930 Survey of Engineering Education, F. L. Bishop. *Jl. Eng. Education*, vol. 21, no. 7, Mar. 1931, pp. 1-77. Survey to secure measure of progress which had been made in engineering education in each institution.

Electric Drive

ROLLING MILLS. Large Rolling Mill Motor. *Elec. Times*, vol. 79, no. 2056, Mar. 19, 1931, p. 527, 2 figs. At present time there is large rolling mill motor on test bed at Stafford works of English Electric Co., for replacing existing steam engine driving 27-in. three-stand reversing mill at Brown Bayley's Sheffield works; it operates on form of Ward-Leonard Ilgner system and comprises main driving motor, flywheel motor generator set, three exciters, slip regulator and necessary control; continuous r. m. s. capacity b.hp. at 30 r. p. m. is 1980; speed range at constant torque, r. p. m. is plus minus 0/30; speed range at reduced torque, r. p. m. is plus 30/70; armature, volts is 536.

PAPER AND PULP MILLS. Synchronous Motors in the Paper Industry, D. R. Shoults. *Paper Trade Jl.*, vol. 92, no. 13, Mar. 26, 1931, pp. 47-50, 3 figs. Advantageous features of synchronous motor drive in paper industry; Korndorffer method; automatic control; pulp grinder drives; Jordon and beater drives; pumps, air compressors and screens; chipper drive. Before Tech. Assn. of Pulp and Paper Industry. See similar article by author, "Electrical Developments," previously indexed from Paper Mill, Jan. 3, 1931, under heading, Paper and Pulp Mills—Electric Equipment.

Electric Lines

HIGH TENSION GROUNDING. Umfassende Erdungsanlage in eimen 380/220 V Verteilnetz (Extensive Grounding Installation in 380/220 Volt Distribution Network), C. Richard. *Assn. Suisse des Electriciens—Bul.* vol. 22, no. 7, Apr. 3, 1931, pp. 166-170, 10 figs. Possibilities available for decrease of ground voltage in case of disturbance; method applied to this purpose in Bassecourt, control test by which it was shown that for all cases of grounding no ground voltages over 50 kv. occurred.

RELAYS. Theory and Application of Relay Systems Low Voltage Transmission Lines—I, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 4, Apr. 1931, pp. 231-237, 17 figs. Three principal types of low-voltage circuits, namely, radial, parallel feeder, and loop systems each require different scheme of relay protection; no detailed study of short-circuit values is ordinarily required for simple radial system, and ordinary over-current relays may be used; with parallel feeders, selective-differential current relays can be applied at generating station end of line, and at substation end, directional over-current relays may be applied; application of relays to loop systems; selective timing of relays.

RURAL — LIGHTNING. La protection contre la foudre des réseaux de distribution d'énergie électrique à basse tension (Protection Against Lightning of Low Voltage Electric Power Distribution Networks), C. Ledoux. *Revue Générale de l'Electricité*, vol. 29, no. 12, Mar. 21, 1931, pp. 467-476, 10 figs. Results of recent investigation have shown that with increasing rural electrification, number of cases of lightning stroke have actually increased; Dauzére together with author have traced relation between geological nature of soil and frequency with which strokes occur; solutions proposed by P. Juppont and C. Dauzére are examined.

Electrolytes

Les Electrolytes Forts (Strong Electrolytes), R. Dufour. *Societe Francaise des Electriciens—Bul.*, vol. 1, no. 2, Feb. 1931, pp. 128-139, 1 fig. Consequences of theory of Debye with regard to conductibility are set forth.

Elevators

ELECTRIC. Elevator Installation and the General Building Contractor. *Gen. Bldg. Contractor*, vol. 2, no. 3, Mar. 1931; pp. 61-68, 6 figs. Method for computing elevator requirements;

typical elevator layout with overhead machinery; power panel and sizes of conduits; parts and devices that may have to be installed on modern high-speed elevator; tabulation of items.

DESIGN. Tells of Elevator Engineering Progress, J. Sozansky. *Power House*, vol. 25, no. 3, Mar. 1931, p. 52. Historical review of electric elevator developments; self-leveling type; operatorless cars; wasted rentable space. Before Montreal District Engins.' Assn.

Frequency

MEASUREMENTS. Ueber die Messung sehr kleiner Frequenzen und ihre Anwendung fuer Fernmessungen (Measurements of Very Low Frequencies and Their Application for Remote Measurement), E. Hudec. *Elektrotechnische Zeit.*, vol. 52, no. 12, Mar. 19, 1931, pp. 380-385, 10 figs. Impulse frequency method; use of ballistic instruments; generation of nearly constant current by means of condenser choke arrangement; decreasing crest intervals through repeated smoothening; repeated switching of short-circuited cable, use of filters, etc.

Furnaces

ANNEALING. Electrically Heated Annealing Furnaces, J. C. Woodson. *Heat Treating and Forging*, vol. 17, no. 3, Mar. 1931, pp. 285-288 and 291, 7 figs. Progress in design and application of annealing furnaces for ferrous and non-ferrous metals; economies for casting annealing runs from 8 to 15 lb. per kw-hr.; temperatures range from 950 to 1,650 deg. fahr., for carbon steel and to 1,950 deg. fahr. for manganese steel.

CALCIUM CARBIDE. La nouvelle usine à carbure et cyanamide de wingles (New Carbid and Cyanamide Plant of Wingles), R. Sevin. *Jl. du Four Electriques*, vol. 40, no. 2, Feb. 1931, pp. 51-58, 10 figs. List of plants in Europe and United States giving types and capacity of electric furnaces; detailed description ,of plant of Société des Mines de Lens, containing 2 lime kilns of 60 tons; carbide plant and 2 Miquet electric furnaces of 6,000 kw.; and their control.

INDUCTION. Tonnage Melting by Coreless Induction, E. F. Northrup. *Fuels and Furnaces*, vol. 9, no. 4, Apr. 1931, pp. 473-478, 7 figs. First of series covering fundamental principles of operation and construction of coreless induction furnace as applied to tonnage melting; development of high-frequency coreless-induction furnace; power requirements and sizes of furnaces and features of construction. (To be continued.)

MELTING. The Russ Induction Furnace. *Engineering*, vol. 131, no. 3404, Apr. 10, 1931, p. 497, 3 figs. Furnace manufactured by Industrie Elektro-Ofen G. m. b. H., Cologne, has normal capacity of 600 kg. and is capable of dealing with all types of non-ferrous metals; important feature is that furnace can be supplied from ordinary mains through Scott-connected transformer.

REFRACTORY MATERIALS. Refractory Materials for Electric Furnaces—I, A. B. Searle. *Metal Industry* (*Lond.*), vol. 38, no. 13, Mar. 27, 1931, pp. 333-335. Copper and its alloys, including bronze, gun metal, brass, copper-nickel, and phosphor-bronze; refining furnaces; lining; use of magnesia; bricks for lining; crucibles; roof; annealing furnaces.

Fuses

HIGH TENSION. Die neue Hockspannungs-Hochleistungsicherung (H-H-Sicherung) der SSW (New High Tension High Capacity Fuse of Siemens Shuckert Company-(H. H. Type Fuse), H. Laepple. *Siemens Zeit.*, vol. 11, no. 2, Feb. 1931, pp. 65-70, 9 figs. New design of which fusing capacity is so high that they may be applied directly for short circuit protection of transformers and line taps, without use of reactors or resistances.

Generators

AUTOMOBILES. Electric Lighting Equipment, H. Cousins. *Automobile Engr.*, vol. 21, no. 278, Mar. 1931, pp. 100-106, 26 figs. Design and operation of various types of dynamos; functioning of regulators with particular regard to consideration of service requirements and reliability; diagrams illustrate C.A.V., Scintilla, and Bosch compensated voltage control system.

COILS. The Importance of Accurately Wound Field Coils, J. C. de la Rosa. *Elec. News*, vol. 40, no. 6, Mar. 15, 1931, pp. 57-58, 1 fig. By rewinding each of 12 field coils of rotary to standard equivalent resistance sparking was completely eliminated.

Heating

Industrial Applications of Electric Heat, L. M. Jenks. *Elec. Specifications*, vol. 3, no. 4, Apr. 1931, pp. 12-13, and 45, 4 figs. Last 10 years have brought development and perfection of so many new and unusual electric heating devices that it seems nothing is impossible; primarily, it may be said that electricity makes better product at lower cost; labor item should receive special consideration where product is to be machined or polished after heating process.

BUILDINGS. The Electric Heating of Buildings. *Engineering*, vol. 131, no. 3402, Mar. 27, 1931, p. 415. Review of two papers read before Institution of Civil Engineers and Institution of Electrical Engineers, respectively; first, by S. M. Saunders and W. L. Swale, describes results obtained from electric thermal storage as applied to building heating; includes list of 22 such installations in Great Britain; second paper, by T. J. Illingworth, deals with economic application of electricity to space heating by all principal systems, and examines several sources of loss of which account must be taken in making comparison between different systems.

HOW VALUABLE Is This Service TO YOU?

THE six-month trial period of publication of "Selected Items from Engineering Index Service" in ELECTRICAL ENGINEERING closes with this issue.

TO GUIDE the Publication Committee in determining whether to continue or discontinue this department the question will be discussed at the delegates conference to be held during the summer convention in Asheville, June 22-26, 1931.

INDIVIDUAL comments and suggestions are invited; they should be made promptly and addressed directly to the A. I. E. E. Editorial Department, 33 West 39th Street, New York, N. Y.

The Electrical Heating of Buildings, R. Grierson. *Instn. Elec. Engrs.—Advance Paper*, Mar. 2, 1931, 48 pp., 21 figs. Types of electric warming equipment; general details and considerations; ascertained monthly cost of continuous electric warming of individual rooms in Central London; graph showing estimated and actual weekly consumption for 20-kw. low-temperature ceiling-panel installation; graph connecting mean temperature-rise and weekly consumption for 20-kw. low-temperature ceiling-panel installation; data relating to thermal-storage installations; data relating to direct electric heating installations, etc.

Hoists

MOTORS. Application of Two-Speed Induction Motors to Monorail Electric Hoists, C. E. Schirmer. *Am. Soc. Mech. Engrs.—Advance Paper*, for mtg. Apr. 13-18, 1931, 2 pp. Use of two-speed squirrel cage induction motors upon monorail hoists has been neglected until recently, and since use of such motors bestows worth while operating characteristics to such hoists at low cost, their more frequent use for such service is assured; chart showing actual speeds for various loads S-1 1-ton 2-speed Robbins & Myers electric hoist.

Hydroelectric

AUTOMATIC POWER PLANTS. Fully Automatic Hydro Power Plant, P. J. Croft, J. R. Desloover and D. Hutchison. *Can. Engr.*, vol. 60, no. 10, Mar. 10, 1931, pp. 11-14, 6 figs. Operation of electrical equipment at Upper Notch Plant of Northern Ontario Power Co.; equipment consists of two 48-ft. head, 6,500-hp., 125-r. p. m. hydraulic turbines direct connected to two 6,500-kva., 11,000-volt, 25-cycle generators; fully automatic control and switching equipment designed for possible remote control from distant supervisory plant; metal-clad switchgear; four 4,500-kva., 11,000/110,000-volt, 25-cycle transformers.

13,000-hp. Fully Automatic Hydroelectric Plant, P. J. Croft, D. H. Hutchison and J. R. Desloover. *Elec. News*, vol. 40, no. 6, Mar. 15, 1931, pp. 39-42 and 48, 7 figs. Upper Notch plant of Northern Ontario Power Co., situated on Montreal River 12 mi. south of Cobalt in heart of Canada's greatest mining district, is one of Canada's largest fully automatic hydroelectric generating stations and represents latest practise in this type of control; it contains two 6,500-kva. 11,000-volt, 25-cycle generators, two 48-ft. head, 6,500-hp. 125-r. p. m. turbines, with fully automatic control.

POWER PLANT EFFICIENCY. Automatic Hydro Plant Economy Proved by Experience, J. M. Gaylord. *Elec. World*, vol. 97, no. 12, Mar. 21, 1931, pp. 532-535, 4 figs. Program of rehabilitation of smaller hydroelectric plants, which has resulted in 17 of these plants being made automatic or semi-automatic by Southern California Edison Co., Ltd., since 1919; 11 years' experience in operation of semi-automatic plants on system has demonstrated very definite savings in operating labor; under manual operation 17 plants required 77 operators while with automatic operation 33 operators are employed; reduced labor cost and housing expense amount to 57 per cent and turnover to 66 per cent; plants pay for themselves in 5½ years.

Hysteresis

Recherches sur la thermodynamique de l'Hystérésis (Studies on the Thermodynamics of Hysteresis), A. Guilbert. *Societé Francaise des Électriciens—Bul.*, vol. 1, no. 2, Feb. 1931, pp. 175-202, 11 figs. Experimental verification of theory expounded in Revue Générale d'Electricité of Jan. 5, 1929, indexed in Engineering Index 1929, p. 970.

Industrial Plants

PURCHASED VS. GENERATED POWER. Was darf die Kilowattstunde kosten? (Permissible Cost of Kilowatt Hour; Diesel Engine vs. Electric Motor), K. Dolzmann., *Elektrizitaetswirtschaft*, vol. 30, no. 6, Mar. 1931, pp. 149-157, 13 figs. General viewpoints for decision in problems of purchase of electric power or generation in own plant are discussed for small and average plants; factors and possibilities to be considered in valuation of Diesel engine and electric motors for this type of plant are analyzed; all necessary data for both types are given.

Insulating Oil

CARBON BLACK EFFECT. Effect of Carbon Black on Insulating Oils, W. B. Wiegand, C. R. Boggs and D. W. Kitchin. *Indus. and Eng. Chem.*, vol. 23, no. 3, Mar. 1931, pp. 273-276, 6 figs. Series of experiments designed to illustrate mechanism of action of carbon black is described; results indicate that action is one of removing moisture and/or electrolytes; brief summary of other methods for treating new and used insulating oils and of more important literature.

DIELECTRIC LOSSES. Dielektrische Verluste in Oelen (Dielectric Losses in Oils), A. Gemant. *Zeit. fuer. Technische Physik*, vol. 11, no. 12, Dec. 1930, pp. 544-545. Proof that losses in oil at low frequencies are due to different process (Wagner effect) from that causing them at high frequencies (Debye effect).

Lamps

Urges Large Lamps in Modern Illumination, M. M. Samuels. *Elec. World*, vol. 97, no. 13, Mar. 28, 1931, pp. 595-597, 1 fig. One peculiar feature has established itself in whole development of modern lighting equipment; it is so persistent and so objectionable that it seems necessary to discuss it in detail; getting away from candles and round bulbs, modern units appear principally in form of flat glass over very shallow fixtures or long glass panels or metal panels likewise on very shallow fixtures, all requiring long tubular lamps. Before Illum. Eng. Soc.

GLOW. Neue Gasentladungslichtquellen (Novel Gas Discharge Sources of Illumination), M. Pirani. *Lichttechnik (Supp. to Elektrotechnik u. Maschinenbau)*, vol. 8, no. 1, Mar. 15, 1931, pp. 1-3, 2 figs. New types in which many of disadvantages of previous types have been overcome; they are manufactured in two types, one with excitation in negative glow light used for television and similar purposes and high-capacity tubes with excitation in positive column; efficiency is 15 to 20 per cent.

Light and Lighting

Moderne Beleuchtungsarten und Leuchten, ihre Anwendung, Anlage und Wirtschaftlichkeit (Modern Methods of Lighting and Equipment, Their Application, Installation and Economy), G. Herkt. *Deutsche Bauzeitung*, vol. 65, no. 11-12, Feb. 4, 1931, pp. 29-36, 48 figs. Object and light intensity; room lighting and color; table showing light intensities for various rooms and locations; outside lighting; various samples of modern interior and exterior lighting; show window, indoor lighting, etc.

Foot-Candle Effectiveness a Measure for Illumination, M. Luckiesh. *Elec. World*, vol. 97, no. 12, Mar. 21, 1931, pp. 553-554. Reasonableness of demand for 10-ft. candles for visual work of this type may be tested; visibility of letters in telephone directory with letters of same size printed on fine book-paper with deep black ink are compared in table.

FILTERS. Filters for the Reproduction of Sunlight and Daylight and the Determination of Color Temperature, R. Davis and K. S. Gibson. *U. S. Bur. Standards—Miscellaneous Pub.*, no. 114, Jan. 21, 1931, 165 pp., 71 figs. Spectral energy distributions; component materials of filters; methods of computation; use of filters; spectrophotometric data; examination and trial of completed filters; preparation of Davis-Gibson filters. Bibliography.

VISUAL EFFICIENCY. Visual Performance Under Daylight, Incandescent, Mercury Vapor, and their Mixtures, K. Y. Tang. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 3, Mar. 1931, pp. 258-274, 6 figs. partly on supp. plates. Rapidity with which detail of test object could be perceived, using, at same levels, usual light sources, alone and in combination; illumination levels studied were 5- 10- and 20-ft. candles in test object; each kind of light was used separately at all three intensities, and combinations of two and three kinds in equal amounts were also used at all three levels.

Lightning

CONDUCTORS. Lynafledere (Lighting Erector), L. Ernst. *Elektroteknikeren*, vol. 27, no. 4, Feb. 22, 1931, pp. 67-79, 12 figs. Study of proper layout and wiring of conductors for all types of buildings; importance of factor controlling action of lightning conductor such as dimensions of building and materials, geological factors, etc.

Materials Handling

MANUFACTURING PLANTS. Material Handling in Mass Production at the General Electric Plant, H. C. Rundle. *Am. Soc. Mech. Engrs.—Advance Paper*, for mtg. Apr. 13-17, 1931, 5 pp. Conveyor system used throughout various buildings where refrigerators are made at General Electric Co., has eliminated congestion, retracing of material routes, delays in schedule, spoilage of materials, and maintenance and replacement of industrial trucks; conveyor serves as traveling stockroom, thus releasing floor space for use in manufacturing operations.

Measurements

ALTERNATING-CURRENT. A New Series of Alternating Current Instruments. *World Power*, vol. 15, no. 87, Mar. 1931, pp. 199-201, 4 figs. Alternating current measurements have long been at disadvantage as compared with direct-current measurement; perfection, during last few years, of dry copper-oxide rectifier has put a-c. testing on different basis; design and operation of rectifier operated instrument.

Metering

THREE-PHASE. The Metering of Three-Phase Supplies, O. Howarth. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 411, Mar. 1931, pp. 381-393 and (discussion) 393-403, 15 figs. Development of electricity supply during recent years has resulted in complexity in metering of three-phase supplies and has confronted meter engineer with task of achieving accuracy under difficult conditions; large bulk supplies are most complex and demand high standard of accuracy for commercial reasons; each additional complexity introduces additional source of error and paper deals with inaccuracies introduced by auxiliary apparatus and special equipment.

Motors

LOADS. Motors for High-Inertia Loads—II, R. E. Emerson. *Indus. Eng.*, vol. 89, no. 3, Mar. 1931, pp. 130-132, 2 figs. Consideration of energy stored in flywheel; use of high inertia in flywheels for handling peak loads while motor runs at full-speed.

MAINTENANCE AND REPAIR. Electric Motor Operation and Maintenance—II, G. H. Emerson. *Power Plant Eng.*, vol. 35, no. 7, Apr. 1, 1931, pp. 423-425. Methods of procedure in determining condition of machines; instruments used; overhauling and repair.

STARTING. Un nouveau démarreur automatique pour moteurs électriques (New Automatic Starter for Electric Motors). *Science et Industrie*, vol. 15, no. 205, Feb. 1931, pp. 85-87 and 92, 3 figs. New electrolytic starter of Rene Planchi Co. in Villefrance sur Saone is described; advantages and field of application are outlined.

TESTING. Tests of Rotating Electrical Apparatus for Electrical Characteristics, A. C. Roe. *Power Plant Eng.*, vol. 35, no. 6, Mar. 15, 1931, pp. 372-373. Practical discussion of proper methods to be employed in electric motor tests.

RAILROAD. Field Shunting and Modern Motor Design, L. B. Hewitt. *Elec. Ry. Bus and Tram Jl.*, vol. 64, no. 1596, Mar. 13, 1931, pp. 141-143, 3 figs. Metropolitan Electric Tramways carried out experiments several years ago, on their 40-hp. non-interpole motors, using field shunting with object of increasing top speed and improving acceleration; this was arranged by means of contactor which was energized on last notch of controller, but under control of specially designed relay which automatically prevented shunting coming into operations if conditions were such that current would rise above predetermined amount.

Comparaison du couplage série-parallèle et du couplage série permanent des moteurs compound dans les systemes à récupération (Comparison of Series-Parallel and of Permanent Series Coupling of Compound Motors in Regenerative Systems), F. Guery. *Revue Générale de l'Electricité*, vol. 29, no. 10, Mar. 7, 1931, pp. 381-385, 3 figs. Comparison of systems of Bacqueyrisse and Lièvre; study has bearing upon essential characteristics of motors and regarded from standpoint of dimensions, all other conditions remaining same; author points to importance of losses in series parallel system.

Networks

Fundamentals of the Medium Voltage Network, D. K. Blake. *Gen. Elec. Rev.*, vol. 34, no. 4, Apr. 1931, pp. 210-217, 17 figs. Modern a-c. low-voltage 120/208-volt network has brought out substantial economies, simplification, flexibility, and standardization involved in network principle; it is not generally recognized that network principle is applicable at medium voltage (4,000 volts) to residential and industrial areas having very low densities.

MAINTENANCE AND REPAIR. De l'organisation du controle permanent de la construction et de l'exploitation d'un réseau rural de distribution d'energie électrique (System for Permanent Supervision, Construction and Exploitation of Rural Distribution Network), L. Melot. *Revue Générale de l'Electricité*, vol. 29, no. 11, Mar. 14, 1931, pp. 429-437, 4 figs. Simple schematic and accurate number identification and index scheme for repairs, extensions, etc. for network system in continuous process of development; method has been successfully applied by author on networks of Loir-et-Cher district.

Ohmmeters

Ein neues Megohmmeter (New Megger), W. Jaekel. *V. D. I. Zeit.*, vol. 75, no. 11, Mar. 14, 1931, p. 316, 2 figs. New type of Siemens and Halske for measurement of insulating resistances of machinery equipment and cables up to many thousands of megohms; easy handling is featured.

Permeameters

TESTING. A Method for the Standardization of Permeameters at High Magnetizing Forces, R. L. Sanford. *U. S. Bur. Standards—Jl. Research*, vol. 6, no. 3, Mar. 1931, pp. 355-362, 6 figs. Apparatus suitable for testing of standard magnetic test bars to be used for standardization of magnetic permeameters with high magnetizing forces; criterion is given for determining when accurate values have been obtained; attention is called to necessity that standards shall be magnetically uniform.

Photoelectric Cells

Photoelectric Tube Increasingly Applied in Industry, J. W. Marshall. *Iron Age*, vol. 127, no. 13, Mar. 26, 1931, pp. 1012-1013, and 1067-1068, 3 figs. Operation principles and industrial application including application to problem of packaging machine design.

Construction, Operation and Characteristics of Photoelectric Tubes, L. R. Koller. *West. Soc. Engrs.—Jl.*, vol. 36, no. 1, Feb. 1931, pp. 15-25, 15 figs. Guide to intelligent selection to accomplish desired results.

Power Factor

Power Factor Correction in Industry, J. Murray. *Blast Furnace and Steel Plant*, vol. 19, no. 4, Apr. 1931, pp. 560-563, 8 figs. Simple method and equipment for power-factor correction in industrial plants.

Radio

AERIAL COMMUNICATION. European Aviation Radio, G. C. Gross. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 341-350 and (discussion) 351-352, 15 figs. Observations made on inspection trip over major European airways; aviation radio in Europe differs from aviation radio in United States in prevalent use of intermediate frequencies exclusively; it may be divided into communication from ground to plane and plane to ground; point-to-point communications in connection with traffic dispatching of aircraft; meteorological communication relating to safe flying conditions.

BROADCASTING. Ten Years of Broadcasting, C. W. Horn. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 356-376, 15 figs. Salient points in development of broadcasting during last decade are reviewed; it is shown that further improvement may be expected with more extensive introduction of higher powered transmitters.

DETECTORS. Grid Circuit Power Rectification, J. R. Nelson. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 489-500, 7 figs. Grid circuit power rectification is investigated by studying ideal rectifier and applying results obtained to case of tube rectifier; characteristic curves are used in this study to obtain optimum conditions for rectification and order of output voltage obtainable; conditions for minimum loading of circuit preceding detector are discussed.

ELECTROLYTIC CONDENSERS. Electrolytic Condensers for Radio Use, F. W. Godsey, Jr. *Electronics*, vol. 2, no. 4, Apr. 1931, pp. 596-597, 4 figs. Principles, equipment and its construction are described; electric and performance characteristics are given.

GENERATOR FREQUENCY. The Design of Radio-Frequency Signal Generators, J. R. Bird. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 438-451, 5 figs. Certain factors involved in designing signal generators free from stray voltage errors are considered; importance of accounting for all circuit details, particularly of wiring elements, is stressed; impedances of certain connections, particularly of output connections from generator to measured receiver, are shown to be important; shielding is considered in some detail.

MEASUREMENTS. Measurement of Resistance and Impedances at High Frequencies, J. W. Labus. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 452-460, 4 figs. It is shown that absolute value of unknown impedance, when put across end of transmission line, is simple function of ratio of currents, measured at beginning and end of transmission line; method has been tested out at wavelength of 21.8 meters, measuring resistance of number of grid leads and of decade box; a-c. resistance was considerably higher than labeled d-c. value; at same time shunted capacity across resistors has been measured and value have been obtained, which agree with expectations.

OSCILLATORS, PIEZOELECTRIC. Measurements of Temperature Coefficient and Pressure Coefficient of Quartz Crystal Oscillators, S. L. Brown and S. Harris. *Rev. Sci. Instruments*, vol. 2, no. 3, Mar. 1931, pp. 180-188, 2 figs. Method of measurement is used whereby variation in frequency of high frequency oscillator can be measured easily to fraction of part in million; audible different tone produced by harmonic of constant, high frequency oscillator and harmonic of second oscillator is compared to tone of variable, calibrated audio frequency oscillator.

OSCILLATION. Oscillation in Tuned Radio-Frequency Amplifiers, B. J. Thompson. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 421-437, 4 figs. Wide use of screen-grid tubes renders understanding of conditions for stability of tuned radio-frequency amplifiers important; in this paper relation between feed-back capacity and other circuit and tube parameters at threshold of instability is computed for one, two, three and four stages.

RESISTANCE. Resonant Impedance and Effective Series Resistance of High-Frequency Parallel Resonant Circuits, H. Iinuma. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 467-478, 11 figs. Example of application of method published in same journal, March 1930, p. 537, "A method of measuring radio-frequency resistance of oscillatory circuit."

SHORT WAVE. Radio Communication on Very Short Waves. *Engineering*, vol. 131, no. 3404, Apr. 10, 1931, pp. 482-483, 7 figs. Experiments are being made on wavelength of 18 cm. by International Telephone and Telegraph Laboratories, Inc., of Hendon, and Laboratories of "Le Matériel Téléphonique," of Paris, between St. Margaret's Bay, near Dover, and Cap Blanc, in France; apparatus used for this purpose, mainly developed by French engineers, consists of terminal equipment of normal design, which is connected to transmitter and receiver.

Railroads

ELECTRICAL ENGINEERING. Report of the Committee on Electricity. *Ry. Age (Daily Edition)*, vol. 90, no. 10B, Mar. 11, 1931, pp. 528-D44-45 and (discussion) 528-D45-46. Synopsis of matter presented before electrical section, Am. Ry. Assn., in October, 1930. Before Am. Ry. Eng. Assn.

ELECTRIFICATION. Thirty-Five Years' Experience with Heavy Electric Traction, S. Withington. *Ry. Age*, vol. 90, no. 12, Mar. 21, 1931, pp. 577-579. Satisfactory equipment has been found; conditions justifying electrification have been determined; need of unified system; era of expansion; early New Haven experience; important developments based on experience. Before New York Railroad Club.

INTERLOCKING SIGNALS. New Control System Used at Electric Interlocking on the Burlington, W. F. Zane. *Ry. Signaling*, vol. 24, no. 3, Mar. 1931, pp. 81-84, 6 figs. Independent control and indication circuits make for simplicity, reliability and freedom from grounds; signal layout plan; tower and power equipment at Downers Grove, Ill.; interlocking machine; outside construction; control and indication circuits; locking and signal circuits.

Remotely-Controlled Interlocking Solves Problem on C. and N. W., S. E. Noble. *Ry. Signaling*, vol. 24, no. 3, Mar. 1931, pp. 85-86, 4 figs. Extensive plant at West Nelson, Ill. controlled from desk levers in tower at another interlocking; track and signal plan of remotely-controlled plant; change in layout and circuit design; lever indication lights; outside construction.

OPERATION STATISTICS. Electric Railways Carry On in a Year Beset with Difficulties. *Elec. Ry. Jl.*, vol. 75, no. 4, Apr. 1931, pp. 197-200. Operating economies obtained in 1930 offset in large measure decreased revenues that were general; reports from 75 companies operating transportation lines in United States and other countries analyzed to give significant statistics; table of condensed financial reports of electrical railway properties 1930-1929.

Rectifiers

HIGH CAPACITY. High Power Rectifiers, J. W. Rissik and H. Rissik. *Engineer*, vol. 151, no. 3923, Mar. 20, 1931, p. 322. Editorial review of paper before Institution of Electrical Engineers, in which increasing field of application of rectifier is attributed to its economy on fluctuating loads, reliability under most severe operating conditions, rapidity with which it can be set to work, and fact that it is unaffected by disturbances on a-c. side; although discussion indicated that certain manufacturers are inclined to favor 600-volt rotaries, experiences on Continent and in America clearly show that engineers frequently specify rectifiers for 600 volts and similar pressures.

MERCURY-ARC. Mercury-Arc Power Rectifier Auxiliaries and Accessories, E. S. Waterman. *Gen. Elec. Rev.*, vol. 34, no. 4, Apr. 1931, pp. 228-234, 16 figs. Exhaust system; vacuum-measuring and regulating devices; ignition and excitation equipment; cooling system; thermal control devices; degassing equipment; resonant shunts and series reactor.

Refrigeration

The Young Engineer in the Refrigerating Industries, A. R. Stevenson, Jr. *Refrig. Eng.*, vol. 21, no. 4, Apr. 1931, pp. 256-258. Survey of possibilities for young engineer in refrigerating industries; classification of engineers by General Electric Co. together with qualifications and possibilities in following four classes: development, design, application and sales engineering.

Regulation

MACHINERY. Ueber die Reglung von Spitzenlast und Grundlastmaschinen (Regulation of Peakload and Base Load Machinery), W. Kieser. *Elektrizitaetswirtschaft*, vol. 30, no. 6, Mar. 1931, pp. 164-170, 13 figs. It is shown what unavoidable frequency fluctuations result in three-phase network from changes in load and how these fluctuations may be kept within narrow limits.

Remote Control

SHIP STEERING GEARS. Der sympathische Fernantried fuer Regel- und Umkehrorgane von Rudermaschinen (Electric Control of Ship Steering Gear), H. Kohrs. *Schiffbau*, vol. 32, no. 3, Feb. 1, 1931, pp. 60-64, 9 figs.; see also brief translated abstract in *Mar. Engr. and Motorship Bldr.*, vol. 54, no. 642, Mar. 1931, p. 116. Disadvantages of normal steering rod and chain control of rudder quadrant; electric installation by A. E. G., known as sympathetic distance control, is so arranged that rudder accurately and immediately follows each unit degree change in rotation of steering wheel; steering engine valve is controlled by geared motor supplied with current from Leonard motor-generator.

Resistors

DESIGN. Stromregelungen bei Laboratoriumsmessungen (Current Regulation in Laboratory Measurements), G. Hauffe. *Elektrotechnische Zeit.*, vol. 52, no. 11, Mar. 12, 1931, pp. 340-341, 4 figs. For exact adjustment of current readings, parallel dimensions of resistors is often required; range of regulation and dimensions of such equipment are discussed and curves for quick design are developed.

Rheostats

Theory of a Combined Series and Potentiometer Rheostat, J. R. Nielsen. *Rev. Sci. Instruments*, vol. 2, no. 3, Mar. 1931, pp. 184-186, 1 fig. Theoretical mathematical analysis pertaining to rheostat designed by Dodge and which permits rapid change from series to potentiometer connection, or vice versa, by simple closing or opening switch.

Sound Measurement

Mesure des intensités sonores par la méthode des scintillations (Measurement of Sound Intensities by Scintillation Method), F. Canac. *Physique et le Radium—Jl.*, vol. 2, no. 2, Feb. 1931, pp. 42-60, 10 figs. Theoretical analysis, measurements and results of experiments.

Spectrum Analysis

Energy Measurements in the Visible and Ultraviolet, F. Bendord and R. F. Howe. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 3, Mar. 1931, pp. 292-301 and (discussion) 301-305, 6 figs. Three common ways of making energy analysis in visible and ultraviolet are photographic method, filter method and monochromator method; these three methods are not fully interchangeable and nature of source of energy often dictates which shall be used; inherent limitations of all three are discussed with reference to measurements of sunlight and some of common sources of light and ultraviolet radiation.

Substations

INDUSTRIAL. Industrial Plant Substations, O. H. Henschel. *South. Power Jl.*, vol. 49, no. 3, Mar. 1931, pp. 67-72 and 74, 9 figs. Notes on indoor and outdoor types of industrial plant substations; general layout and equipment design; typical installations; multiple transformer stations; combination stations; secondary substations.

LIGHTING. Outdoor Substation Lighting, H. E. Hutter. *Elec. Rev.*, vol. 108, no. 2781, Mar. 13, 1931, pp. 460-461, 5 figs. Principles of underlying provision of adequate illumination to meet requirements both of normal operation and emergency repair work; samples of lighting units to be used, design and construction and details are given.

Synchronizers

AUTOMATIC. Automatic Synchronizing Equipment. *Power Engr.*, vol. 26, no. 300, Mar. 1931, pp. 105-109, 12 figs. Principles of and apparatus for synchronizing a-c. generators automatically; Brown-Boveri apparatus for automatic synchronizing; Reyrolle system; performance curves and diagrams.

Transformers

AUTO. Auto-Transformers for Starting Induction Motors, A. Holt. *Power*, vol. 73, no. 13, Mar. 31, 1931, pp. 508-510, 3 figs. Although induction motors designed for starting on full voltage have come into general use, there are vast numbers in service that are started on reduced voltage; voltage supplied by auto-transformers; practical discussion of selection and care of electric equipment.

GROUNDING. Grounding Transformers, H. Fahnoe and E. G. Reed. *Elec. Jl.*, vol. 28, no. 4, Apr. 1931, pp. 226-230, 10 figs. On three-phase power system grounding transformer is frequently used not only to provide neutral ground connection, but also to limit to predetermined value current flowing during line-to-ground fault; notes on star-delta connected grounding transformers; interconnected-star grounding transformer; thermal protection of grounding transformers; equivalent kv. rating of grounding transformers; numerical examples.

INSTRUMENT. Current Transformers, G. W. Stubbings. *Elec. Rev.*, vol. 108, no. 2871, Mar. 13, 1931, pp. 462-463, 1 fig. Critical study of various methods of determining errors; vector relationships; absolute methods of testing; comparison methods of testing; elimination of detector errors; novel comparison methods.

Waves

TRANSIENT. Die Umbilding der Wellenform durch Kapazitaeten und Induktivitaeten bei durch Funken ausgeloesten Wanderwellen (Reshaping of Wave Form by Capacity and Inductance of Spark Generator Traveling Waves), W. Schilling. *Archiv fuer Elektrotechnik*, vol. 25, no. 2, Feb. 21, 1931, pp. 97-122, 21 figs. Voltage characteristic of waves in simple circuit; approximate equations for large breaking capacities; influence of capacity and inductivity in wave form and voltage.

ULTRA-SHORT. Sur la réflexion des ondes électromagnétiques (Reflection of Electromagnetic Waves), C. Gutton and G. Beauvais. *Académie des Sciences—Comptes Rendus*, vol. 191, no. 26, Dec. 29, 1930, pp. 1418-1420; see also translated abstract in *Experimental Wireless*, vol. 8, no. 90, Mar. 1931, pp. 143-144. Experiments with reflected ultra-short waves from 6 to 10 m. and results obtained.

Welding

HYDRAULIC TURBINES. Hydraulic Turbine Repaired by Electric Welding, C. R. Reid. *Power*, vol. 73, no. 12, Mar. 24, 1931, pp. 478-479, 3 figs. Badly damaged Francis-type runner of 20,000-hp. unit repaired at cost of only $2,274.

PIPE LINES. 1930 Piping Jobs Simplified by Welding. W. R. Wood. *Heat. and Piping Contractors Nat. Assn.—Off. Bul.*, vol. 38, no. 4, Apr. 1931, pp. 37-39, 9 figs. Advantages of welding as exemplified by Empire State and Cornell Medical Center installations.

SHEET STEEL. Sheet Metal Welding Formulae. *Sheet Metal Industries*, vol. 4, no. 11, Mar. 1931, pp. 984, 986, and 989, 3 figs. Up to present, literature of welding processes reveals almost complete absence of formulas; first attempt to obtain such laws carried out by D. Seferian; results of tests are shown in table and are also represented graphically.

SHIPBUILDING. Experiences with an Electrically-Welded Ship. *Engineering*, vol. 131, no. 3403, Apr. 3, 1931, pp. 460-461, 3 figs. Fullagar, now known as Shean, was launched in 1920; vessel has several times been aground and on each occasion, later examination showed keel and bottom plating to have stood severe conditions without ill effect; after more than 11 years of service it has been impossible to trace any undue corrosion in welded structure; experiences form remarkable demonstration of possibilities of electric welding in ship construction and valuable tribute to methods and materials of Quasi-Arc Co.

TRACKS. Welding Manganese Track Work, H. H. George. *Traction Shop and Roadway*, vol. 4, no. 3, Mar. 1931, pp. 77-80, 16 figs.; see also *Elec. Traction*, vol. 27, no. 3, Mar. 1931, pp. 125-127, 16 figs. Knowledge of, and adherence to fundamental requirements, found through experience, results in long life for track work reconstructed by welding; Cleveland's welding rules; frequent repairs to frogs handled quickly by welding; switch repairs that save money and prevent derailments.

Industrial Notes

Lamp Companies Merge.—Plans for a merger have been approved by the directors of the Hygrade Lamp Company of Salem, Mass., and the Sylvania Products Company and the Nilco Lamp Works, Inc., both of Emporium, Penn. Combined sales of these companies amounted to approximately $9,000,000 for the year 1930. The Emporium and Salem units each manufacture incandescent lamp bulbs and radio tubes. The electric lamp bulbs are manufactured and sold under a license agreement with the General Electric Company.

A New Rectifier.—A new line of heavy duty rectifiers has been announced by the B-L Electric Manufacturing Company, St. Louis, supplementing the small rectifiers which the company has produced for some years. These rectifiers are constructed entirely of metal plates without any moving parts and are of rugged construction. They are used to obtain low voltage direct current from the ordinary alternating-current lines and for this purpose require the use of small step-down transformers. Many applications exist for the use of such rectifiers in the fields of radio, sound-film equipment, signaling, alarms, industrial control, etc. B-L Electric Mfg. Company, 19th & Washington Avenue, St. Louis.

New G-E Plant Near Completion.—The new million dollar Cleveland wire works plant of the General Electric Company, which is being erected at South Euclid, on the outskirts of Cleveland, is rapidly nearing completion, according to E. J. Edwards, engineer in charge of plant construction for the incandescent lamp department. The new plant, which is to be devoted to the manufacture of filament wire, represents the largest arc-welding job ever attempted in the Cleveland territory. More than a thousand tons of structural steel are going into its construction. The building covers an area 493 feet in length by 320 feet in width. It will provide 185,000 square feet of floor space. Tentative production schedules call for a plant output of more than 300,000 miles of filament wire during the year 1932. The structure is scheduled for completion August 15 by the Austin Company, of Cleveland, who built the original Nela Park in 1912.

A New Power Filter Unit.—The Square D Company, Detroit, has announced the introduction of a power filter unit for supplying noiseless, non-pulsating, direct-current power from ordinary alternating-current circuits and applicable to telephone circuits, intercommunicating systems, public address systems, talking picture equipment and other sound producing apparatus. No auxiliary equipment is necessary. The new device is noiseless and has no moving parts. Square D Company, Detroit.

Installing Underground Cable.—By means of a special plow built by the General Electric Company, the plow being available for rental purposes, parkway or underground cable can be installed beneath sod and in locations where a minimum disturbance to the ground is desired. A reel of parkway cable is located at one end of the circuit run, and is mounted on supports so that it may unreel easily. The plow is connected to a tractor, and one end of the parkway cable is connected to the plow blade. It may be used to best advantage when installing parkway cable within the curb line of a street, around tree roots, poles, etc. The depth limit of the plow is 15 inches.

Trade Literature

Airport Lighting.—Catalog 218-FA, 30 pp. Describes a complete line of electrical equipment necessary for airport lighting. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Vitrohm Resistors.—Bulletin 507, 8 pp. Describes vitrohm resistors and rheostats for radio. Ward Leonard Electric Company, Mount Vernon, N. Y.

Carbon Brushes.—Catalog 12, 42 pp. Describes a complete line of standard and special brushes for motors, generators and synchronous converters. Boxill-Bruel Carbon Co., Columbia Park, Ohio.

Small Generator Units.—Bulletin 1908, 12 pp. Describes belt driven generators, turbine generator units, portable gas engine-driven power units and electric service plants up to 15 kw. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Line Hardware.—Bulletin 5, 4 pp. Describes guying specialties, including guy hooks, eye nuts, curved ribbed washers, double guy blocks, Shull boltless guy clamps, and "pick-up head" anchor rods. Malleable Iron Fittings Company, Branford, Conn.

Th Stenode.—Bulletin 1, 24 pp. Describes the "Stenode," for which the claim is made that it is by far the most selective radio receiver. Drawings of various circuits are included. The Stenode Corporation of America, Hempstead Gardens, L. I., N. Y.

Instruments.—Catalog F Part 2, 48 pp. Supplement to Part 1 of Catalog F. Describes all new General Radio instruments'for electrical measurements at communication frequencies, and announces many important specification changes in the others. General Radio Company, Cambridge, A, Mass.

Circuit Breakers.—Bulletin 37, 16 pp. Describes Pacific Electric multi-break oil circuit breakers. These 69-kv. breakers incorporate many new features and improvements over former types. Pacific Electric Manufacturing Corp., 5815 Third Street, San Francisco.

Remote Control Cars.—Bulletin 1239, 12 pp. Describes automatic and remote control quarry cars which are controlled by one operator from a distant point. The idea of remote control is not entirely new, but the scheme described in the bulletin depends upon the use of alternating current, which has not heretofore been employed in such operation. The Atlas Car & Mfg. Co., Cleveland.

Manual of "Megger" Practice.—A pocket manual, 96 pp., treating in a comprehensive manner on the subject of electrical insulation and uses of insulation testing instruments. It includes valuable data on the characteristics of insulation and suggests how and where to look for insulation defects in electrical equipment. Sixty-seven illustrations are included. James G. Biddle Company, 1211 Arch Street, Philadelphia.

Lightning Arresters.—Bulletin 313, 64 pp. Describes a complete line of lightning arresters, including Keystone crystal valve lightning arresters for high and low voltage a-c. service and for low voltage d-c. service; Garton-Daniels lightning arresters for low-voltage a-c. and d-c. service and for standard and high voltage d-c. railway service; Keystone and Protex radio lightning arresters; and ground fittings. Electric Service Supplies Co., 17th & Cambria Streets, Philadelphia.

Motors.—Bulletin 165. Describes seven distinct types of squirrel cage motors, comparing them as to their starting torques, starting currents and cost. Speed-torque curves and tables make a thorough comparison of the seven types to enable a proper selection for different applications. The bulletin also describes construction details, and has a section on "mechanical variations" in which roller bearings, totally-enclosed, fan-cooled, vertical and three-bearing motors are discussed. There is also a section on multi-speed motors and control equipment. Wagner Electric Corporation, 6400 Plymouth Avenue, St. Louis.

W. S. LEE (F'13) sagacious president of the Institute, in his summer convention address interprets the spirit of modern engineering in one word—*coordination*—and indicates therein a fruitful field of endeavor for the young engineer. (*See page 512.*)

STEEL MILL engineers especially may be interested in the development of twin-motor drive for heavy rolling mills. (*See page 506.*)

SUMMER CONVENTION news will be especially interesting to those unable to attend and participate in its varied technical and recreational program. (*See page 517.*)

OVERSEAS TELEPHONE service by radio first was introduced more than four years ago and now is accepted as quite the ordinary thing. Recent developments are described by F. A. Cowan (M'29). (*See page 476.*)

THE LIGHTNING SEASON being at hand, it is pertinent that serious attention be given to the effects of this phenomenon upon electric power transmission. Much has been accomplished by the Institute's lightning subcommittee since its appointment in 1926; the work has been greatly expedited within the past two years by the use of several new instruments, and by the concentration of effort upon a few systems. Important results of recent investigations, contained in twelve Institute papers, have been abstracted and correlated in six articles. (*See pages 478 to 502.*)

PACIFIC COAST convention with its excellent technical program embracing subjects from cathode drops to industrial applications, and its delightful admixture of recreational and entertainment features, offers first-class vacation possibilities. Why not take advantage of the special convention rates available at Tahoe Tavern for the entire convention week? (*See page 514.*)

ANNUAL MEETING of the Institute comprised the opening session of the summer convention; results of the recent election of officers, and the annual report of the board of directors, were among the important matters receiving attention. (*See page 522.*)

DR. W. J. FOSTER (F'16) recently awarded the Lamme Medal, was presented the trophy with appropriate ceremony during the summer convention. (*See page 519.*)

"FOR THE PURPOSE of studying the present and any proposed future activities of the Institute," the new Institute policy committee was appointed at the May 19 meeting of the board of directors. (*See page 523.*)

H. B. SMITH (F'13) past-president of the Institute, has resigned his post at Worcester Polytechnic Institute, and plans to resume professional practise. (*See page 524.*)

Relay Protection for A "Close-Linked" System

Relay-protection design involves a detailed study not only of the required standards of service but also of the general design and layout of the power system to be protected. The "close-linked" type of system of Chicago and the special relaying system which it demanded, are discussed.

By
T. G. LeCLAIR
Member, A. I. E. E.

Commonwealth Edison Co., Chicago, Ill.

SERVICE RELIABILITY required of electric power systems today is accomplished fundamentally by two general means. One might be termed "preventive engineering" and the other "protective engineering." The former presupposses a system and its related equipment designed and built to a degree of perfection that makes failure impossible while the latter aims to minimize and localize such troubles as may occur.

Obviously, *complete* prevention of failure is impossible of practical attainment; hence protection against line and apparatus failure becomes a necessity. Theoretically a fault is not considered serious provided the capacity and extent of equipment involved is small and that the protective equipment will operate to isolate the trouble quickly. From a power-system standpoint, therefore, protective devices are installed to protect the system as a whole, rather than individual lines or equipment, against the disturbing effects of faults.

General System Design

Of first importance in the matter of power-system protection is the question of the general system design; and so far as the larger cities of the United States are concerned, this may be classified into three principal types as follow:

1. "Loose-linked" system of Detroit.

Each group of distribution circuits is provided with a substation and for each group of substations there is a generating station of sufficient normal capacity to care for the group of substations operating from its buses. The loose-linking characteristic is found in interconnection of areas which are served by different generating stations with tie cables so designed as to have relatively low capacity compared to the total load emanating from a generating station, but of sufficient capacity to serve normal and emergency power interchange between different load districts. Thus, the different load areas are all linked together for normal service, but each is subject to quick and complete isolation from its neighbors, minimizing the possibility of any system-wide disturbance which might result from a serious fault in any load district. (See A. I. E. E. Trans., Vol. 48, Oct. 1929, pp. 1080-2.)

2. "Synchronized-at-the-load" system of New York.

All supply cables are short; generating stations are close to the load and all are of closely similar efficiency. Transmission and tie-lines are so arranged that any station may feed to any or all load centers. Thus the loss of any one source will not interrupt service at the load; power is widely available under emergency conditions and yet relatively low short-circuit currents arise, a factor of prime importance. (See A. I. E. E. Trans., Vol. 48, Oct. 1929, pp. 1080-2.)

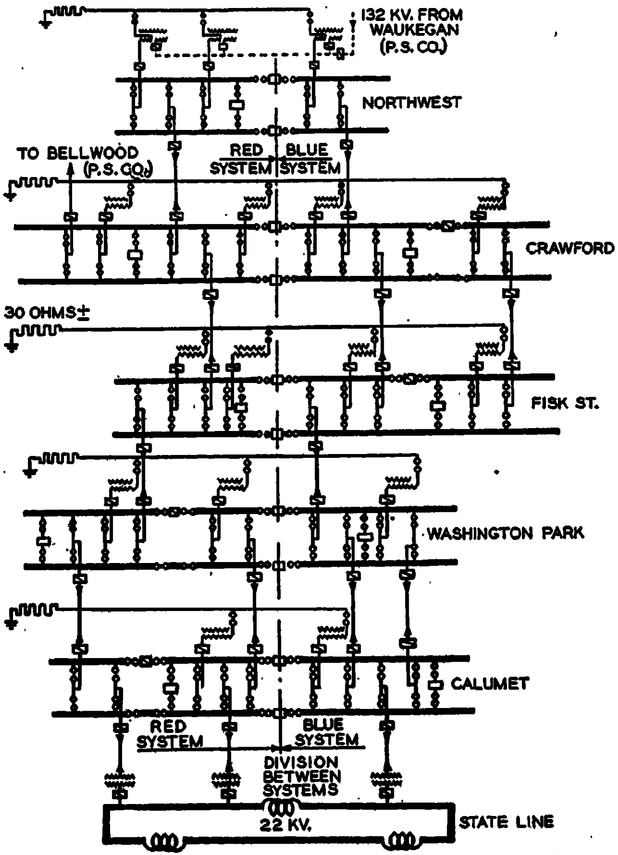

Fig. 1. Schematic diagram of Chicago "close-linked" transmission system. Note especially that system is normally divided into two distinct parts ("red" and "blue"), also that generating stations are connected by 66-kv. low-reactance tie cables

---

From talk presented informally at a joint meeting of the Chicago Section of the A. I. E. E., and the Western Society of Engineers, held in Chicago, Oct. 28, 1930. * Not published in pamphlet form.

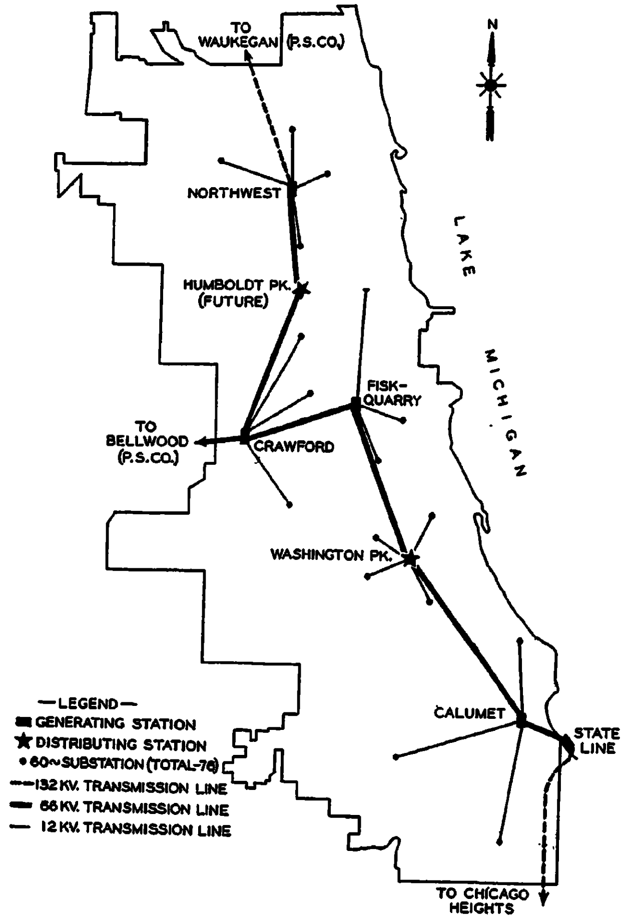

Fig. 2. Semi-geographic layout of Chicago 60-cycle system showing 66-kv. inter-station "bus"

3. Bus or "close-linked" system of Chicago.

This system is illustrated in Figs. 1 and 2 where various independent loads may be noted, each fed from separate sources. All sources are tied together through reactors, permitting a direct energy interchange. Such a scheme has certain limitations, the most serious being that short-circuit currents are large, thus requiring special means of accomplishing satisfactory circuit interruption.

For a power system such as the one in Chicago where several generating stations have been built more or less as units, the close-linked system is considered ideal. Of the generating stations indicated in Figs. 1 and 2, Fisk and Quarry stations are "old-timers," the newest units having been installed more than fifteen years ago. At Crawford station the oldest unit was installed some six years ago, while the oldest at State Line is less than two years old. Because operating efficiencies among these stations vary greatly, it is necessary to provide for a transfer of load between different sources in order to realize the best over-all operating economy.

This load transfer is accomplished through a 66-kv. "inter-station" bus which stretches the entire length of the city as may be seen in Fig. 2. All six steam-electric generating stations representing the aggregate installed capacity of 1,298,000 kw. are interconnected by means of this 66-kv. transmission bus. Electrically these station interconnections are extremely short, their reactance being so low that with maximum load the total voltage variation from one end of the city to the other does not exceed three or four per cent.

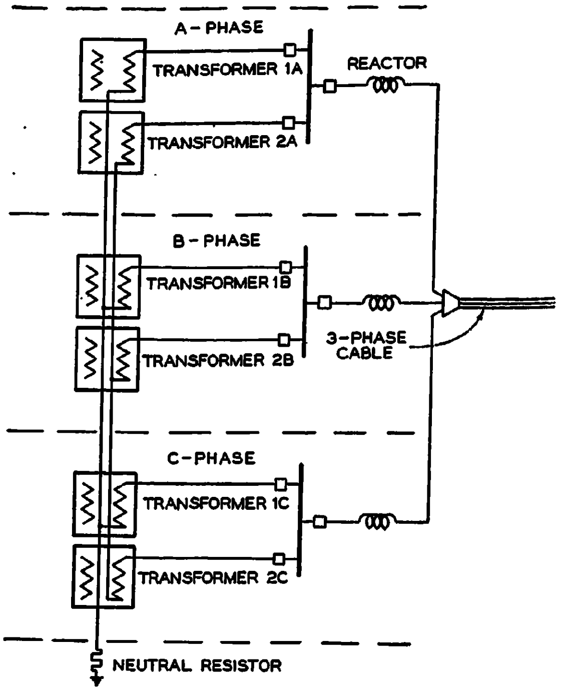

Fig. 3. Illustrating isolated-phase grouping of two transformer banks

With this system it is possible to tap off at any given station the load needed for that particular local territory the transformer capacity of the station in question being governed of course by the load to be served. However, there are certain difficulties involved because with this close-linked system any one fault member will involve the entire system. For this reason the system has been split throughout into two parts. The 66 kv. buses of the two parts are capable of interconnection in the various stations but only in rare cases are they actually operated tied together. Thus, there are practically two duplicate systems; and trouble on one of them will not interfere with the other. For purposes of clarity some of the illustrations refer to these two parts as "red" and "blue" systems.

ISOLATED-PHASE CONSTRUCTION

Short-circuit current which would arise if the two systems were operated tied together would be practically impossible to handle with the existing circuit-interrupting equipment and conventional group-phase construction. Even with the systems separated, the problem of handling the interruption of fault current is a serious one. An expedient which has done more than any other single thing to make practicable the operation of such a system is the isolated-phase construction. With this type of construction it is possible to throw the entire station capacity upon one bus, where emergencies require, yet the short-circuit current is low enough so that an ordinary circuit breaker can interrupt it satisfactorily.

A diagrammatic presentation of this isolated-phase arrangement is given in Fig. 3 where two transformer banks are shown so connected that both the phase unit of the bank itself and the phase leads from the bank are widely separated physically from those of adjacent phases. The leads are not brought close together until they have passed through suitable reactance capable of limiting the short-circuit current to an easily interruptable value.

Most important among the features of the isolated-phase system is the relatively-high resistance or reactance employed in the neutral connection. Normally, in a star-connected system all loads are carefully balanced between phases and practically no current flows through the neutral; on the other hand in the isolated-phase system, practically all fault current will flow through the neutral since phase-to-phase faults are almost impossible on account of the great physical separation between exposed parts. This greatly simplifies the protection problem without interfering in any way with the system regulation.

With the isolated-phase construction of a 66-kv. outdoor terminal not only are the phase leads separated by a distance of 30 ft. or more, but by a metal screen of generous proportions as well. (See Fig. 4.) In indoor generating station construction whether for 12 kv. or 66 kv. each phase is housed in a separate room or on a separate floor. This type of construction is used also for the newer and larger substations; in the older and smaller substations the arrangement of lines and buses is depended upon to prevent complete shut-downs. No two lines to a substation group originate on the same line bus but are divided among the different sections of the generating station main bus.

FAULT BUS FOR PROTECTING SWITCHING EQUIPMENT

As mentioned in the beginning of this article, protective equipment must be installed to guard against the disturbing effect of those failures which system design cannot prevent. To be ideal, of course, protective devices must disconnect faulty equipment only, and in addition operate instantaneously; this ideal is achieved or approached wherever economically justifiable.

Practically instantaneous clearing of faults can be secured by employing the fault bus, a device for system protection which is of maximum benefit with isolated-phase construction. It consists essentially of a separate bus isolated from ground but connected through a current transformer to the main ground bus. Each unit group of switching equipment has its own fault bus through which the oil switch tanks, insulator bases, and other equipment cases are grounded and to which flash plates are connected. These flash plates are so arranged that no flashover can occur without the resultant current flowing through the fault bus and its current transformer. A relay in this current transformer secondary circuit can be set for instantaneous operation and the unit group wherein the fault occurs will then be quickly isolated. A schematic diagram of the fault-bus connections in a generating station switchhouse may be seen in Fig. 5. Here two main buses with outgoing lines are connected to so-called line buses; all can be fed from either one of the main buses. The dotted lines represent the fault-bus connections. If a fault occurs on the line bus marked (*x*) the fault current will flow through the fault bus and current transformer and actuate relay 3 which will trip the four line switches and also the two group switches *A* and *B*, thereby

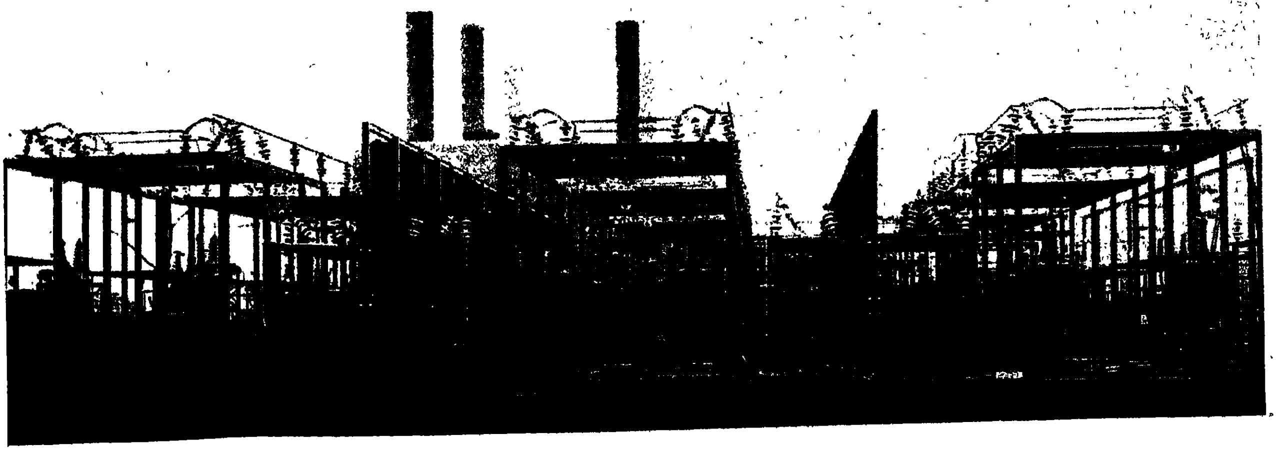

Fig. 4. Outdoor 66-kv. switching terminal at Calumet generating station. Note isolated-phase construction and high screen barriers between phase groups

isolating the fault. For faults between two unit groups, time sequence relaying is employed to prevent unnecessary switch-openings. For instance, if a fault occurs on switch *E*, relay 4 will first trip the line and group switches; and if the fault is not cleared within 0.7 sec., relay 7 will trip all switches connected to the red main bus section where switch *E* is connected.

Fault buses are now installed in all new generating stations, distribution stations, 66-kv. terminals and some of the larger substations to protect against bus and equipment failures.

DIFFERENTIAL RELAY PROTECTION FOR GENERATORS AND LARGE TRANSFORMERS

A differential method of relaying is employed to disconnect faulty generators and 66-kv. transformers from the system. For generator protection the simple conventional scheme with a sensitive relay is used. For three-winding transformers, however, this simple arrangement cannot be used, especially where one or two windings are equipped for tap changing under load. Further difficulties are encountered because of the 30-ohm neutral resistance in the 66-kv. system; consequently, one set of relays is connected differentially across all three windings. (See Fig. 6.) These relays are of the *percentage differential* type; that is, they will trip when the tripping current exceeds a predetermined percentage of the load current. (See "Percentage-Differential Transformer Protection," p. 361, May 1931 issue of ELECTRICAL ENGINEERING.) On account of the tap-changers, this percentage for these relays must be relativly high, a value of 50 per cent being used. For faults on the 66-kv. winding close to the neutral, because of the neutral resistor limiting the fault current, a more sensitive relay is required. A second set of differential relays, connected across the 66-kv. winding, and with a setting as low as from 2.5 to 5.0 per cent, is therefore provided. In addition to the differential relays, ordinary overload relays are installed on the 12-kv. side of main and regulating transformers.

PILOT-WIRE RELAYING FOR TIE-LINE PROTECTION

As shown in Fig. 1 the 66-kv. tie lines between generating stations are connected to buses at the transmission terminals, these buses being divided into several sections and operated split or tied together depending upon the system requirements. The best way known to isolate instantaneously a faulty line on this type of system is the pilot-wire-relay scheme. This system, while rather costly, is justified by the size of the lines and the importance of the service. A three-phase scheme is employed with four pilot wires, pilot transformers, balancing resistors, and capacitors. It has been found that the capacitors can be omitted in the Chicago system, where the lines are all less than eleven miles long.

SECTIONALIZATION

In addition to the usual protective schemes, there are in use on this system means for preventing the spread of trouble; these cannot be classed with protective devices. As previously mentioned, the 66-kv. system is divided into two parts which are normally operated as independent units, so that trouble on one-half cannot affect the other half, even should the protective devices fail. On the 12-kv. system, the stations also are separated into two or more parts for the purpose of preventing the spread of trouble. These two parts may be permanently separated through reactance, which will limit the flow of short-circuit current; or they may be operated normally tied together and automatically sectionalized by relays. Normally these sectionalizing relays will not interrupt any service but are intended to separate each section and its dependent lines into a number of self-sustained units. In this way, failure of protective devices on one of these units will not spread the trouble to the other units.

SUBSTATION AND 12-KV. LINE PROTECTION

The isolated-phase construction with fault-bus protection has been extended to some of the later and larger substations; in others, line relays are relied upon for the proper clearing of faulty buses. For line protection, ordinary overload directional and balanced differential relays are used.

Up to a few years ago, the systems so far touched upon would have been all that required consideration when planning reliable supply for a city like Chicago. Now, however, some of these stations are shut down part time and more efficient generating capacity outside of Chicago is depended upon for the supply. This energy is delivered over long overhead transmission lines and their protection becomes part of the problem of service security.

One great difficulty with overhead lines is their susceptibility to lightning—a problem not yet completely solved. Still another problem to consider when large amounts of power are transmitted over great distances is that of stability. Several means for increasing the stability of a line have been introduced, however, most common among which are, (1) increasing the speed of clearing faults; (2) providing high speed excitation; and (3) changing system connections.

CONCLUSION

Past progress toward the goal of perfectly reliable service has been along three principal paths; namely, (1) improving the individual units of equipment, (2) providing faster and more reliable isolating devices, and (3) designing the complete system so that the loss of individual parts may be tolerated. In the future the metropolitan system should make its greatest advances along the line of general system developments based upon the present high quality of equipment. Marked improvement in the reliability of long overhead lines with a high degree of exposure may be expected, particularly when the power delivered must meet the exacting standards of metropolitan service.

Magnetic "Iron" Perfected by Research

THIRTY years ago great quantities of iron were necessary in cores of electrical devices to prevent undue electrical loss. High temperatures caused magnetic deterioration of the metal. Even alloys of apparently constant chemical composition had varying magnetic properties. In view of this obstacle, progress in transformers of electrical currents was especially difficult.

Then came the first big improvement; Hadfield in England discovered silicon as an alloying element with iron. In 1903 silicon steel appeared there, and a little later here. This new steel cut losses in half. They were again cut in half by better mill practise and improved raw material. For the next decade further progress was slow, improvements small. Things had again reached an impasse.

About that time, an effort was made by the writer at the University of Illinois to make iron alloys of only the purest materials obtainable. For nearly sixteen years the research has continued; one of its main objects being to determine the properties of really pure iron, because iron is the basis of all important magnetic materials. Who would have believed that the elimination of a few thousandths of one per cent of carbon could be responsible for raising the maximum permeability of iron from perhaps 10,000 to 50,000 with corresponding decreases in hysteresis? Yet this has been amply demonstrated.

The work has been fraught with exceptional difficulties since it dealt with subjects like strain in the crystal structures, and with impurities in thousandths of one per cent. Furthermore, these very small amounts of oxygen, carbon, and sulphur exist in solution in solid iron—like sugar in solution in a glass of water.

Commercially, the most important results have come from the study of iron-silicon and iron-nickel alloys. Laboratory results are not rapidly translated into commercial practise. Five years after the first published results, no appreciable effect appeared in commercial steel. In 1920, after much discussion and many experiments, the steel mills began to put some of the

---

From an articl written by Dr. T. D. Yensen of the Westinghouse Research Laboratories for *Research Narratives*, Feb. 15, 1931, published by the Engineering Foundation, Inc., 29 West 39th Street, New York, N. Y.

findings into practise and there has since been a steady annual improvement in the quality of electrical sheet iron. Now the commercial material is almost as good as the laboratory product of a few years ago.

Hipernik (an alloy of half iron and half nickel) is another product of the laboratory. At first used in high-quality radio receiving sets where it contributed largely to the elimination of distortion of sounds in reproduction, it has gradually entered other important fields. In the near future we may find this alloy in many places where iron-silicon alloys are used today. Here again the difference between the ordinary alloy and hipernik cannot be ascertained by usual chemical analysis; radically new methods had to be devised.

(EDITOR'S NOTE: Under date of May 25, 1931, the American Rolling Mill Company, Middletown, Ohio, announced that this special alloy now is being rolled commercially from 6-ton ingots.)

Associates who have contributed to this success include G. H. Cole,[1] A. A. Frey, T. Spooner[2] and N. A. Ziegler. In its large practical results, this long and painstaking research is a vivid example of how the affairs of men are affected by scientific work which only a few years ago would have appeared hopelessly theoretical.

Overseas Radio Telephone Service

More than four years have elapsed since the installation of the first transoceanic radio-telephone circuit between New York and London. Some of the more recent developments in this class of service are discussed here.

American Tel. & Tel. Co., New York, N. Y.

SHORT-WAVE RADIO has played an important part in the extension of the telephone frontiers beyond the boundaries of this North American continent. During the four years which have elapsed since the first commercial telephone service between this country and Europe was inaugurated all of the world's overseas telephone extensions have employed short-wave radio. With the exception of the original New York-London circuit which operates on 1,500 m., the wavelengths used have ranged between 14 and 100 m. Today there are three short-wave circuits between New York and London supplementing the original long-wave circuit. In addition to these there is a circuit between New York and Buenos Aires, Argentina, circuits from New York to ships at sea, and one from London to Sidney, Australia (See Fig. 1). All of these circuits are available to telephone users in this country, and in addition to these facilities, extensions are being planned between New York and Hamilton, Bermuda, New York and Rio de Janeiro, and San Francisco and Honolulu, Hawaii. Since such factors as susceptibility to noise in transmission across equatorial regions, and the character of other transmission variables, including economic considerations, favor the use of short *vs.* long waves, all of these circuits will employ short-wave radio.

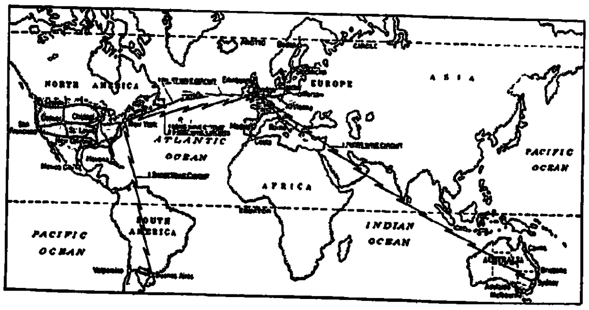

Fig. 1. Radio links between telephone systems of North America and other countries

NEW YORK-BUENOS AIRES CIRCUIT

A schematic layout of the New York-Buenos Aires circuit may be seen in Fig. 2. A crystal-controlled high-powered transmitter employing water-cooled vacuum tubes with an output of between 15 and 20 kw. is employed at both terminals. Associated with this transmitter are directive antennas which increase the signal strength by an amount equivalent to a 20- to 50-fold increase in transmitted power. Upon leaving the transmitting station, signals travel by the well-known sky-wave route to the foreign terminal. Radio receiving stations of the double-detection type equipped with automatic gain control and directive antennas are employed. To care for the changing transmission conditions these directive antennas are provided for three separate wavelengths. The received speech signals are transmitted from the receiving station to the foreign subscriber over land lines.

These directive-antenna arrays improve the receiving conditions by strengthening the signal received from the selected direction, reducing the effect of noise and other

signals coming from other directions. The automatic gain-control feature compensates for moment-to-moment variations in the strength of the received carrier wave and when radio noise conditions are satisfactory the complete receiving system is capable of satisfactorily utilizing a signal having a field strength as low as one microvolt per meter. This performance has been made possible by the selection of a receiving site sufficiently isolated to minimize local interference, and by the careful design of the component parts of the receiving system.

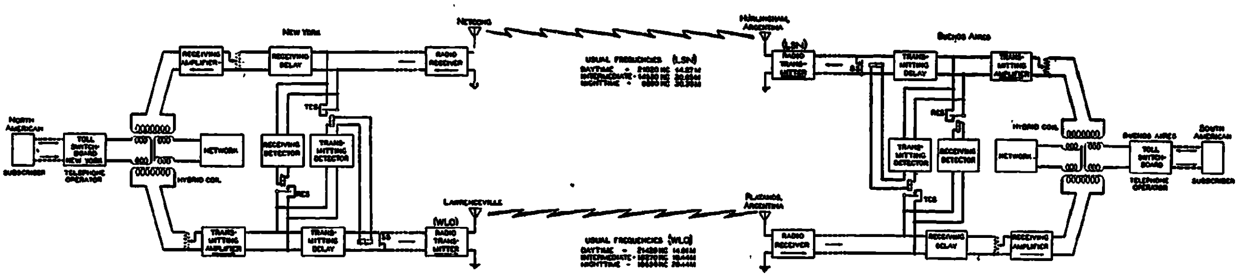

Fig. 2. Schematic layout of New York-Buenos Aires radio-telephone circuit

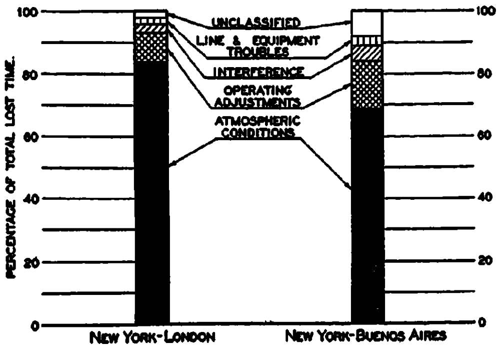

Fig. 3. Analysis of time lost on two short-wave radio-telephone circuits for a typical summer month

At the terminal points voice-operated-relay switching equipment disables the radio path in one direction while speech is traveling in the opposite direction. It also maintains the transmitting side of the circuit in a disabled condition when no speech is being transmitted. This automatic switching simplifies the transmission problem by resolving the two-way circuit into two one-way circuits. The switching-relay circuits are carefully adjusted to compensate for any changing transmission conditions, thus minimizing interruptions due to false operation of the relays.

Once the circuits of the type under consideration have been established their performance is controlled largely by the condition of the transmitting medium at any particular time. Since the control of this medium is beyond the scope of human endeavor, the operating problem becomes one of maintaining the component parts of the system in good condition and operating the system as a whole to best advantage.

LOST CIRCUIT TIME ANALYZED

A comparative analysis of the lost circuit time for a typical summer month on the New York-Buenos Aires circuit and one of the New York-London short-wave circuits, is shown in Fig. 3. It may be noted in each case that the major percentage of lost time is due to atmospheric conditions.

Whereas normally the conditions are good, there are times when, due to some disturbances of a nature not clearly understood, radio transmission from certain paths is seriously affected. These disturbances have been correlated reasonably well with abnormal activity in the magnetic field of the earth and are commonly known as "magnetic storms."

These occur at irregular intervals and at times result in reducing the signal strength at the receiving points to unusable values. Transmission on all frequencies is affected to a greater or lesser degree, and the time in each 24-hr. period during which reliable transmission can be expected is materially reduced. This interference usually is seriously effective for several days preceding and following the day on which the storm is actually at its height.

The equipment used in the short-wave radio circuits is so designed and constructed as to minimize the likelihood of trouble. In addition, spare units of equipment have been provided for replacing equipment which would be most subject to trouble or which would require considerable time to repair. These precautions, together with a systematic testing routine, account for the small amount of lost time due to equipment troubles.

In view of their adaptability to transmission over great distances and the rapid progress that is being made in improving, simplifying, and reducing their cost, short-wave radio systems are of outstanding importance in the development of world-wide telephonic communication. What the future will bring can only be guessed; but it does seem reasonably certain that for the next few years the short-wave circuits will continue to occupy a prominent position in the forward march toward the development of a world-wide telephone service.

That the concerted efforts of power companies and electrical manufacturers to combat the disturbing influences of lightning already have borne fruit, is attested by the greatly reduced transmission line outages from this cause. Results of recent investigations in this field as described in twelve Institute papers form the basis for the six articles which follow.

Theoretical Studies Laboratory and Field Tests Operating Experiences Lead to Effective System Protection Against

THE LIGHTNING PROBLEM as it affects the operation of electric light and power systems, according to Sporn logically divides itself into three parts:

1. Theoretical and laboratory investigations which include mathematical studies and various analyses of lightning phenomena.
2. Field research with natural and artificial lightning, which studies are enhanced from year to year by developments and improvements in equipment.
3. Evaluation of the effects of different devices and of line design upon the mitigation of lightning disturbances by the study and analysis of practical operating records.

This and the five articles following in this issue of ELECTRICAL ENGINEERING present a collection of theories and facts relating to these different aspects of the lightning problem. These articles have been prepared from twelve Institute papers (see Table I) of which three treat mainly the theories involved in lightning studies; two deal entirely with field investigations of surges imposed on transmission systems by means of artificial lightning discharges; four present the results of field investigations of natural lightning discharges; one gives the results of analysis and interpretation of a large quantity of operating data collected on systems in service; while one is devoted to a description of a new device designed to protect line insulators against flashovers.

An attempt has been made to correlate information from these different sources, outlining in some detail the most recent findings in this important field, and indicating the relation between these latest disclosures and previously accepted ideas. Additional information has been obtained quite recently regarding the mechanism of lightning formation and discharge, and some new theories have been advanced. It is realized generally, however, that present ideas still are entirely inadequate for a thorough understanding of the fundamental nature of lightning. Nevertheless, in spite of the obscurities, several important disclosures have been made. These are outlined in the paragraphs that follow and are based upon the results given in the entire set of twelve papers.

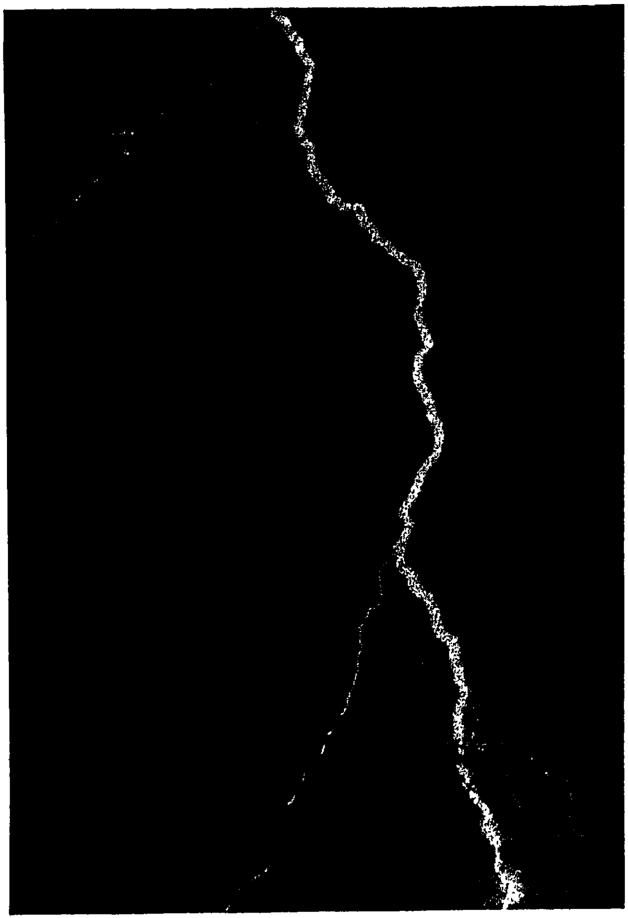
Concerted action in theoretical and field studies of natural and artificial lightning phenomena received its first great impetus in 1926 with the appointment of the lightning subcommittee of the A. I. E. E. transmission and distribution committee. This subcommittee was established primarily to assemble more definite information regarding the nature and characteristics of lightning and related electric system disturbances; also to ascertain possible protective measures with which to combat the troublesome disturbances. A general pooling of efforts and equipment followed, various utilities and the principal equipment manufacturers cooperating in practically all of the investigations subsequently carried out.

A paucity of suitable instruments hindered early work, the well-known klydonograph being practically the only instrument available. With that instrument it was possible to ascertain some idea as to the magnitude of lightning voltages, but the extremely short duration of such discharges made extremely difficult their accurate study with apparatus having mechanical recording elements. Development of new instruments and their liberal use, and the concentration of major field efforts upon a relatively few representative systems have been the two factors chiefly responsible for the rapid acceleration of lightning studies during 1929 and 1930.

DIRECT HITS AND INDUCED SURGES

Line surges can be very harmful whether due to direct hits or to induction from cloud discharges or strokes to nearby objects. It is generally recognized, however, that disturbances arising from direct strokes to line conductors or to ground wires on well grounded steel structures, subject lines to more severe punishment than do induced surges in general. The induced surge appears to be of minor importance on lines as highly insulated as are the 220-kv. lines in eastern Pennsylvania and New Jersey. Of course, voltages also can be induced on the conductors when a direct hit on the tower or ground wire occurs. Whether or not these induced voltages will cause a flashover appears to depend upon line insulation and tower footing resistance.

Lightning Disturbances



Westinghouse E. & M. Co. Photo

WAVE SHAPES

Wave shapes of lightning surges depend upon many varying factors, chief among which are the origin of the surge (whether induced or due to a direct stroke), duration of cloud discharge, and cloud height. Some of the many cathode-ray oscillograms which have been taken both of induced surges and direct strokes are reproduced in this symposium. Wave fronts varying in length from 2 to 9 microsec. with length of tail to half-voltage of from 6 to 40 microsec. have been observed. The total lengths of these waves vary from 10 to 160 microsec. In an oscillogram of a direct stroke estimated as terminating on the line 125 ft. from the laboratory, a voltage rise of 1,540 kv. per microsec. was recorded (see Fig. 16). Most of the oscillograms, however, were obtained at some distance from the point of incidence and, therefore, do not show the true wave shape at that point, having suffered distortion in traveling along the line.

Negative surges have steeper fronts than do those of positive polarity. It has been estimated that the former may have fronts as short as 1 microsec. or less, while the probable minimum for the latter is approximately 5 microsec.

ATTENUATION, DISTORTION, AND REFLECTION

Traveling waves arising from lightning discharges undergo a continuous change as they proceed along the line, the general tendency being a slowing down of the front, a flattening of the tail, and a general increase in total length. Corona appears to be the greatest cause of this phenomenon; hence it follows that the reduction in wave crest is more rapid above than below the critical corona voltage. Attenuation is more rapid for extremely high-voltage surges and according to indications may be as high as 1,000 kv. per mi. of travel.

Surges impressed upon three parallel conductors evidence a more rapid slowing down of front but lower rate of attenuation than do waves on a single conductor. Reflections from line sections of changing impedance and from terminal equipment also are factors in wave shape change; characteristics of these reflections can be predicted by means of "lattice" diagrams.

CREST VOLTAGES AND CURRENTS

The maximum voltage recorded in any of the tests described was 5,000 kv., measured on a wood pole line at a point about 4 mi. from the point of incidence of a direct stroke (see Fig. 21). Indications are that the voltage of a direct stroke may be as high as from 10,000 to 15,000 kv. A maximum discharge current of 670,000 amperes was reported, determined by adding together the tower ground currents for the several towers affected. This method may be subject to some errors; its merits are a controversial matter. Other indications, however, also point to a maximum of several hundred thousand amperes.

POLARITY

No definite conclusions have been drawn in regard to polarity, but it seems well established that both positive and negative cloud potentials exist. However, more di-

rect strokes of negative polarity have been recorded than those of positive polarity, while the majority of induced strokes appear to be positive. The question of polarity is important inasmuch as negative strokes have been observed to have steeper wave fronts, while positive polarity surges attenuate more rapidly.

EXTENT OF SYSTEM AFFECTED

Flashovers have occurred in the majority of cases on only one phase, but usually involve corresponding insulator assemblies at two or more adjacent towers. Evidences of direct-stroke currents have been observed in as many as five or six towers. On highly insulated ungrounded lines, such as the wood pole line previously mentioned, traveling waves of dangerous magnitude may reach substation equipment and cause flashovers there, since such equipment in general is less highly insulated than the line equipment. Under these conditions, especially good lightning arrester equipment is required at the stations. On well-grounded steel tower lines where flashovers do not occur, severe electrical disturbance usually is limited to a few structures, and any surge propagated over the conductor will be of extremely low magnitude.

FLASHOVERS AND TRIP-OUTS

Flashovers from direct strokes may occur if (1) the stroke terminates on the line conductor; (2) the stroke terminates on a tower of high surge impedance, thus raising the tower potential with reference to the conductor; (3) the stroke terminates on the ground wire between towers and the potential is of sufficient magnitude to cause flashover at that point, in which case flashover at an adjacent tower is certain to occur.

Experience has shown that direct strokes may occur at towers of low footing resistance without subsequent flashover. Whether or not a trip-out will result when flashovers occur depends upon whether the amplitude and polarity relations of line voltage and current are such as to permit the establishment of a power arc at the time of flashover. That flashovers can occur without causing line trip-outs is definitely shown by records of a lightning surge of 2,500 kv. which did not cause a trip-out but which most certainly did cause a flashover.

Induced surges also may cause insulator flashovers with resultant line trip-outs, especially when direct strokes occur to nearby objects. The likelihood of these surges reaching flashover value, however, is minimized by the installation of conventional overhead ground wires.

Effects of Grounding

Beneficial effects of overhead ground wires have been proved without doubt both by special investigations and operating experiences. Operating experiences have shown also that two ground wires are much more effective than one alone. The effectiveness of ground wire protection depends to some extent upon tower footing resistance; where this is high, special grounding cables or counterpoises can be used effectively to lower the surge impedance of the structures. Counterpoise cables are most effective when extended out radially from the tower foot, but in practical cases are restricted by right-of-way limitations to the two directions along the line. Operating experiences show, however, that flashovers do not always concentrate at towers having high footing resistance.

Line Design

General requirements for good lightning protection are low lines, short spans, low tower footing resistance, and overhead ground wires. The number and position of overhead ground wires will depend upon the conductor configuration and the number of circuits. Spacing between conductors and ground wires must be large in order to prevent flashovers at mid-span.

For effective protection against direct strokes the tower footing resistance should not be more than 4 or 5 ohms. Where this is impractical special overhead ground wire structures, known as diverters, may be installed if the economics of the situation permit.

Protective Devices

Lightning arresters are especially applicable at substations to protect terminal equipment against lightning damage. The principal qualification is that they be placed reasonably close to the equipment they are designed to protect. Arresters also are used on transmission lines where provision cannot be made economically for the installation of overhead ground wires.

In this connection field investigations have shown that arresters of the expulsion type will successfully interrupt dynamic current follow-up. A promising new device now under development consists of a hollow fiber tube with electrodes at either end, wherein the breakdown element is the air contained in the tube. Grading shields have not been found to decrease the number of line outages, but, when properly installed, they do minimize the damage to insulators, line hardware, and conductors, and reduce the amount of cascading required.

Theories of Lightning Discharge and Traveling Waves

Recent theoretical findings concerning lightning and traveling waves are discussed in this article. When corroborated by field tests, these results furnish information from which a systematic scheme of protection can be established. "Direct-hit" wires above ordinary "sky wires" are suggested and discussed.

LIGHTNING may cause abnormal voltages on power transmission lines in either of two different ways—by direct stroke or by induction. Some understanding of the formation of these surges is necessary before a systematic scheme of protection can be evolved.

According to Fortescue and Conwell the thundercloud consists of small particles of water-vapor, each carrying a minute charge of electricity, free negative charges attaching themselves to the vapor particles. Since the mobility of the resulting charged moisture particles is very small the only way in which a discharge can take place is through ionization. This ionization process results in the formation of a lightning streamer.

Some streamers will never reach the earth because of an insufficient charge in the cloud. This would indicate that lightning disturbances resulting from streamers which do reach the earth will vary somewhat in severity over a wide range, depending upon the amount of energy which the cloud is capable of discharging. The energy in the streamer itself is mainly potential energy until the earth or a structure is reached, when its potential energy is changed instantly into kinetic energy in the form of a current wave moving at the velocity of light into the earth or structure through the path pioneered by the streamer. Negative reflections pass up the same lightning channel, increasing the discharge current and also the gradient in the cloud. This in turn tends to extend more streamers throughout the cloud until the available energy is decreased below the point necessary to maintain the lightning channel.

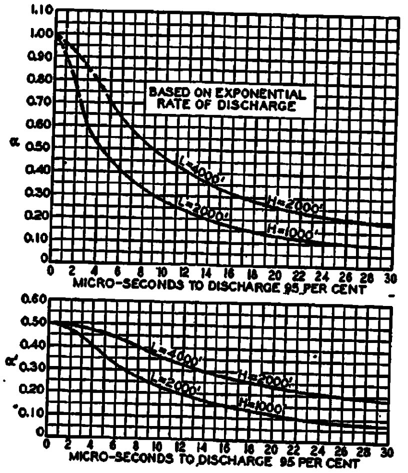

Fig. 1. Values of α for calculating lightning voltages induced on transmission lines (exponential rate of discharge assumed)

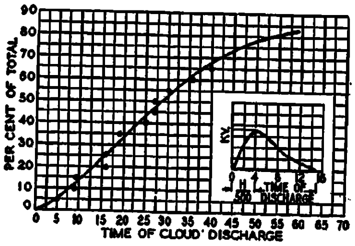

Fig. 2. Duration of cloud discharges determined from cathode-ray oscillograms

Complete data on the limiting value of lightning stroke potentials are not yet available but fairly good approximations for potentials ordinarily encountered may be made. Since voltages may be caused either by direct strokes or by induction, it is of practical importance to be able to estimate the numerical values of these voltages under both conditions.

Direct Strokes

Peek discusses the question of direct lightning strokes from the theoretical aspect and arrives at several interesting conclusions. The chance of a line being struck by a direct bolt increases of course with increasing height of line. On a flat plane without projections, a tower may be hit when the distance from it to the projection of the storm center is less than from four to ten times tower height. This factor is based upon the assumption that the nearest object will be hit and has been called the direct-hit ratio.

Where lines are brought through a right-of-way with nearby trees practically equal in height to the line, the hazard of direct strokes reaching the line should be very small. It has been found that a tree can direct or attract a lightning stroke as readily as can a metal tower because the charging takes place with low current and over a relatively long time. Also it has been found that the chance of any particular tower being struck does not depend upon its footing resistance, but that the resulting voltage on line insulators following a hit does depend almost entirely upon such resistance.

As a rule, a tower is more likely to be struck than the line. When this occurs the resulting voltage between line and tower, or ground wire, or across the line insulator string, is given by the formula

$$V_e = K I R$$

where K is a constant depending upon the tower and ground-wire configuration, I is the tower current (which will be less than the total-stroke current by the current flowing in the ground wire), and R represents the tower footing resistance. Fairly accurate approximations can be made by assuming $K = 0.8$. The importance of keeping the tower footing resistance low is obvious from the above formula if immunity from direct-stroke sparkovers is to be obtained.

As an example, it can be shown that on a line insulated with 14 disk insulator units, a tower resistance of 40 ohms would result in a voltage of 3,200 kv. on a 100,000-ampere direct bolt. In order to keep the voltage below sparkover value of this line the tower resistance must not exceed 20 ohms. For higher discharge currents the tower resistance must be correspondingly lower to prevent the establishment of sparkover voltages.

Induced Surges

When voltages occur by induction their polarity is opposite to that of the cloud source and their numerical values may be calculated by the formula

$$V = G h \alpha$$

where V is the voltage above ground, G is the potential gradient in volts per foot (100,000 is the accepted maximum value), h is the line height in feet, and α is a factor depending upon the duration of cloud discharge and the distribution of bound charge. Values of α calculated on the basis of an exponential rate of cloud discharge may be seen in Fig. 1. Since an instantaneous cloud discharge is impossible, α always will be less than unity. As plotted in Fig. 1 α is the factor to be used in computing maximum potentials at the point of origin while α' is the factor for computing the crest voltage on the resulting traveling wave.

That the distribution of bound charge affects the shape of the traveling wave to a much less extent than does the law of cloud discharge had been determined previously. The bound charge therefore can be assumed to be rectangular without involving any marked departure from the true shape of the traveling wave. Cathode-ray oscillograms are especially useful in determining the shape of traveling waves. If taken reasonably near the source and not badly distorted by sparkovers, losses, or reflections, they give practically the complete life history and characteristics of the stroke. In oscillograms of this nature the time from zero to crest voltage gives a measure of the length of bound charge, while the time from crest to zero on the falling part of the wave is the duration of cloud discharge. In addition the equivalent distance for one-half the time to crest approximates the height of the cloud. These ideas regarding the origin and characteristics of induced surges are concurred in by both Bewley and Peek.

Bewley points out, however, that as the time of cloud discharge increases, both α and α' (Fig. 1) decrease and rapidly approach equality for discharges slower than 10 microsec. He has computed also that for an average line height of 60 ft., and a 3,000-ft. rectangular bound charge (allowing 10 microsec. for the cloud discharge) the maximum voltage for induced traveling waves is somewhat less than 2,000 kv. A similar computation by Peek agrees with this value. It is evident that high-potential induced surges are possible only with very short waves and that for cloud discharges of long duration induced surges become quite harmless.

Peek, in discussing further the relations between traveling waves and cloud characteristics, states that information can best be obtained by cathode-ray oscillograph measurements made in the field. When the waves become distorted, however, the front no longer is of value in obtaining information on cloud height or length of bound charge because the values would be too high. The lengthened tails on such distorted waves indicate a longer duration than actually obtained. A good approximation, however, is that the duration of discharge is twice the time from crest to half voltage on the tail part of the wave. Since due to reflections a wave may persist for a number of loops, only the first loop is of interest for this approximation. Fig. 2 shows the results of a large number of such oscillograms where the crest voltages were higher than 100 kv. and line sparkover did not occur.

When the time and manner of discharge have been determined the lightning discharge current also can be ascertained mathematically. However, since these currents appear quite large (400,000 amperes for a typical case) confirmation by actual field measurements is necessary before final conclusions can be drawn.

General Properties of Traveling Waves

Bewley continues his theoretical study of traveling waves as outlined briefly in the following paragraphs.

The behavior of an n-conductor system having mutual inductance and capacitance between conductors can be formulated by a partial differential equation of the $2n$ order in both time and space derivatives. Although a formal solution for such an equation exists, it is too complicated to be of much use from an engineering point of view. However, solutions for (1) a no-loss system, (2) a completely transposed system, and (3) the steady-state alternating-current condition, are easily obtained.

If a line is free from losses the differential equations of the system are satisfied by pure wave functions. If the line is completely transposed so that every conductor occupies the same relative position as every other conductor, and for the same distance, then the possible average velocities between terminals are reduced to two in number. The conventional method of calculating the steady-state alternating-current behavior of a transmission line by using constants to neutral is a very special case, but is rigorous for a single-circuit, three-phase, completely transposed line.

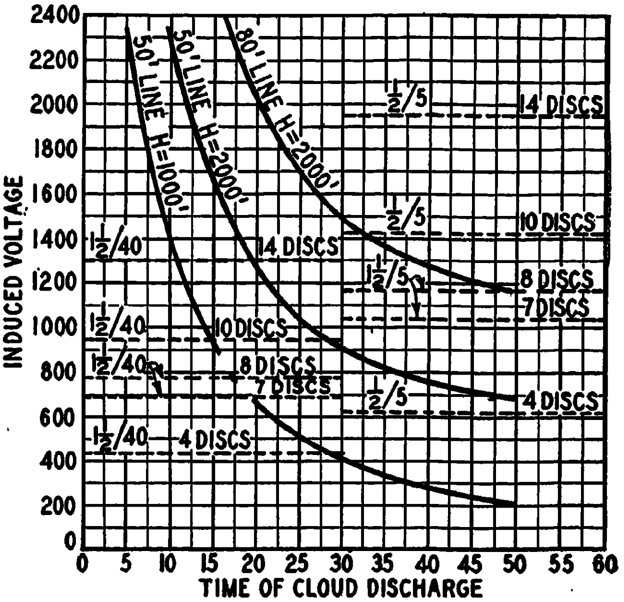

Fig. 3. Induced voltages on 50- and 80-ft. lines for different cloud-discharge durations and two cloud heights

For free traveling waves on a multi-conductor system, the energy is equally divided between the electrostatic and electromagnetic fields. However, when waves moving in the opposite direction pass through one another (as occurs from reflections at transition points) the energy balance is upset so that the energy resides more in one form than in the other. Pure traveling waves, which can occur only in a no-loss circuit, in general have as many possible velocities of propagation as there are conductors in the circuit. When the conductors are overhead wires these velocities all reduce to the velocity of light.

The behavior of traveling waves at general transition points (see Fig. 4) can be determined by a system of simultaneous equations involving the reflection, refraction, and transfer operators of the circuit. By a fortunate coincidence these can be expressed by one or the other of two equations containing only three parameters. In solving for different terminal conditions, therefore, it is necessary merely to tabulate the values of the three parameters for different cases with reference to the proper equation. Thus a large mass of information can be condensed into a relatively small space.

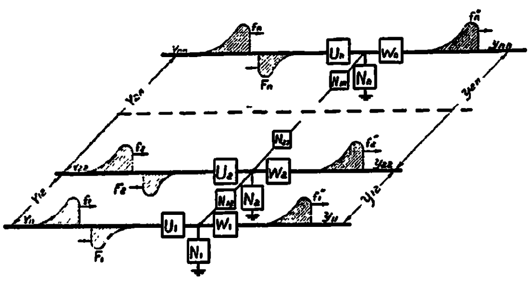

Fig. 4. Incident- and reflected-wave relations on a multi-conductor system

Typical Shapes of Traveling Waves

The principal shapes of most natural waves may be represented by the difference of two exponentials, the actual waves of course being serrated by minor irregularities. The cathode-ray oscillograph has proved its usefulness in investigating this phase of the problem, and during the past few years many oscillograms of natural lightning waves have been obtained under widely varying conditions. These have provided fairly definite information as to the general shape and characteristics of such surges. In calculating the effects of traveling waves, therefore, these characteristics must be kept in mind so that the influence of fronts, tails, and lengths of the waves may be evaluated. Three different methods for calculating waves of arbitrary shape are given by Bewley as follow:

1. Express in operational notation, combine with the function representing the reflection or refraction operator, and solve the resulting operational equations.
2. Consider the wave as made up of a series of infinite rectangular waves, adding the solutions corresponding to each component rectangular wave.
3. Express the wave as the sum of several functions for which the individual solutions are known or can be found, and add these solutions.

Each of these methods is subject to certain advantages and limitations. With the first method the operational equations usually are so complicated that a solution either cannot be obtained at all, or only by the most laborious and complex process. The second method is only an approximation, of course. In a great many cases, however, it is sufficiently accurate and has the advantage of simplicity especially where the incident wave is greatly complicated.

The third method, in which the wave is represented as a sum of functions for which the solutions are known, is quite useful and practicable. By properly compounding a few simple functions almost any desired wave shape can be reproduced with a fair degree of approximation. This process is illustrated for a few typical cases in Fig. 5 where the elementary waves considered are (1) infinite rectangular, (2) simple exponential, (3) uniformly rising front, (4) damped sinusoid, and (5) difference of two exponentials.

Attenuation and Distortion

Bewley continues that it usually is justifiable and convenient to perform traveling-wave calculations on the assumption of no losses, and then to compensate for attenuation by an exponential decrement factor determined experimentally. Corona, it is generally agreed, is the chief cause of attenuation and distortion. It levels off the top and elongates the wave, but its effect is somewhat variable depending upon the weather and other conditions.

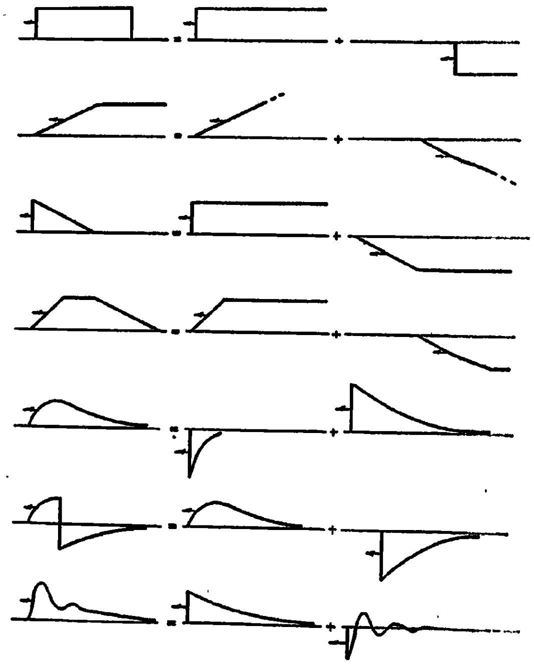

Fig. 5. Separation of complex waves into two simple waves

Effects of line losses are threefold; (1) voltage and current waves are attenuated, (2) wave shapes are distorted with time, and (3) the waves depart from exact similarity, so that the simple linear proportionality factors (called the surge impedances) and the linear equations cease to hold except as approximations. Skin effect and normal line losses, according to Bewley, are of minor importance and may be neglected in comparison with corona losses.

Brune and Eaton in discussing the theoretical aspects of their line tests state that the very front of the wave suffers the greatest attenuation (becoming less and less steep) the net result being that the entire wave is lengthened and the crest voltage is reduced. This is caused not only by corona, but also by skin effect and series resistance in the line. Attempts to calculate the effect of corona by assuming an equivalent "leakance," however, are stated to be erroneous, since the corona does not establish a conducting path by means of which charges may leak off the line except at voltages near sparkover values.

To clarify somewhat the mechanism of corona, Brune and Eaton explain that usually the area surrounding a conductor becomes conducting only within an envelope of limited radius, and as the voltage rises above the corona voltage, charges enter this envelope thereby decreasing the voltage on the front of the wave. Such charges will remain in the corona envelope as long as the conductor voltage is high; when it falls the charges return to the conductor thus tending to maintain the high voltage on the tail of the wave. In this exchange of charge between conductor and corona envelope energy is lost, but no charge.

Fig. 6. Typical lattice diagram for computing successive reflections

Successive Reflections

In a number of important problems, such as in the theory of ground wire, the effect of short lengths of cable, and trunk lines tapped at short intervals, it is necessary to consider the effects of successive reflections of traveling waves. Difficulty sometimes is experienced in keeping track of such reflections where numerous reflecting points exist. To solve this difficulty lattice diagrams have been devised which show at a glance the position and direction of motion of every incident, reflected, and refracted wave on the system at every instant of time. In Fig. 6 a typical lattice diagram has been set up for a line containing three reflection points. These reflection points may consist of any combination of impedances in series with the line or shunted to ground. The circuits between these points may consist either of open lines or cables, and may have different surge impedances, velocities of wave propagation, and attenuation factors.

To construct such a lattice for any particular case it is necessary only to scale the junctions at intervals equal to the time taken by the wave to traverse each section between junctions. A suitable time scale then can be chosen (shown as the ordinate in Fig. 6) and the diagonals drawn in.

Reflection and refraction operators can be placed at the top of the lattice over the respective junctions with suitable directional indicators. These may be seen at the top of Fig. 6 where a and a' are respectively the reflection operators for waves approaching from the left and right, b and b' are respectively the refraction operators for waves approaching from left and right; α and β are attenuation factors for the sections between junctions. These operators, of course, are operational expressions involving the impedance functions of the junctions, but no restrictions are placed on their generality. Starting at the origin of the initial incident wave at the top of the lattice, the reflected and refracted waves at each junction can be obtained by applying the operators of that junction to the incident wave arriving there, then proceeding until the lattice has been completed. In these lattice diagrams it will be observed that:

1. All waves travel "down-hill."
2. The position of any wave at any time is determined from the vertical time scale at the left of the lattice.
3. The total potential at any point at any instant of time is the superposition of all the waves which have arrived at that point up to that instant of time, displaced in position from each other by intervals equal to the instants of their time of arrival.
4. The previous history of any wave is easily traced.
5. The effect of attenuation is included.
6. If it is desired to carry the computations to a point where it is not practical to place the various operators directly on the lattice itself, then

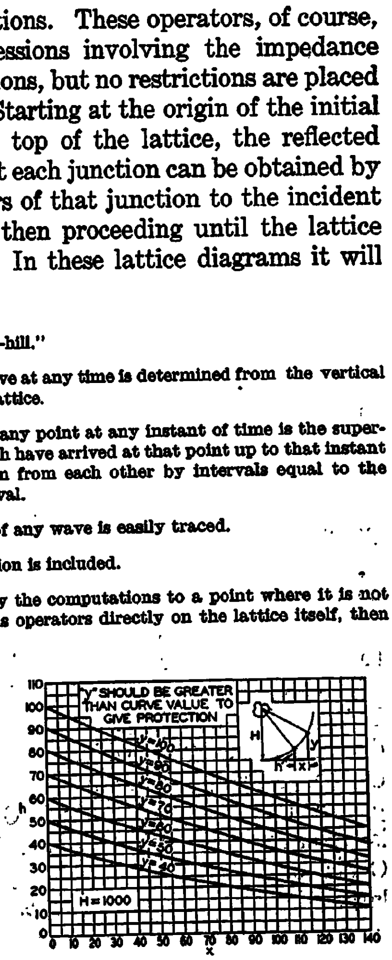

Fig. 7. Minimum ground wire heights (y) to shield line conductors against direct strokes from clouds 1,000 ft. above

the arms may be numbered and the operational expressions tabulated in a suitable form.

Dowell has used this method in analyzing the results of some of his investigations with artificial lightning impulses applied to typical sections of lines. These are treated in another part of this symposium.

OVERHEAD GROUND WIRES

To protect line conductors from direct hits the ground wire or wires should be at a sufficient distance above the line wires to "attract" the lightning. Peek has found that the shielding effect of ground wires depends not only upon their vertical height but also upon the horizontal distance between their projections and those of the line wires. Fig. 7 shows minimum values for the ground-wire heights required to protect the line wire against direct hits from a cloud 1,000 ft. above the earth. The respective heights for the line and ground wires are represented by h and y, and the horizontal distance between by x.

While this position for the ground wire may shield the line wire from the initial hit, it does not protect against side flashes or sparkovers from a struck ground wire to a line wire, where the hit takes place at some distance from a tower.

Hazards due to direct hits of this nature can be reduced by special provision in ground-wire design and tower spacing, but usually these are considered unnecessary since the chance of a hit between towers is small.

Even with ground wires installed, however, immunity from outages due to direct hits can be approached only with low tower footing resistance to maintain low tower potentials, and with heavy line insulation. In some cases in addition to the overhead ground wires with which lines now usually are equipped, "direct-stroke" wires strung above the ground wires may be necessary to prevent flashovers from midspan hits. The advantageous effect of short span construction can be simulated by supporting the ground wire not only from the main towers, but also from intermediate towers interposed between the main towers. Low-footing resistance usually can be obtained by means of buried (counterpoise) wires connected to the tower legs. The adoption of such an expedient will be governed, however, largely by cost considerations.

In rocky and mountainous country where it is difficult to obtain low tower footing resistance special ground-wire construction or line shielding may be necessary. It is possible also to prevent outages by some form of device at the tower which would permit lightning to discharge freely to ground, but which would prevent power current from following. One such device which is operating successfully is the fused grading shield. Other devices have been brought out, but still are largely in the experimental stage.

LIGHTNING SURGES AND LINE CONSTRUCTION

Formation of line surges due to lightning strokes is analyzed by Fortescue and Conwell in accordance with the type of transmission construction used. Their two classifications are (1) wood pole lines and steel tower lines not equipped with ground wires, and (2) steel tower lines equipped with ground wires.

Considering first wood pole lines unprotected by ground wires or spill-over gaps, the potential attained by a surge before the structure breaks down may be very high. When the structure flashes over, the potential is reduced quickly to a value which depends upon the surge impedance of the conductor and of the wood poles and ground. Some simple calculations using accepted formulas and constants show that a stroke which would deliver a 15,000-kv. surge on a single line conductor will appear at 77 per cent of this value on all three line conductors when all three are struck. Under such conditions flashover to ground will occur immediately, but a potential of about 30 per cent of the original surge will still exist. In the case of steel towers without ground wires the surge potential of the conductor after flashover will be the same as that of the tower so that one insulator string only may be flashed over if the surge impedance of the tower is low. The likelihood of another flashover taking place at adjacent towers is dependent upon the intensity of the stroke and the impedance of the tower circuit where flashover first occurs.

Where ground wires are used on steel tower construction, assuming that the protection is adequate, flashovers still may occur if the line is inadequately insulated. When a bolt strikes the ground wire at midspan the resulting surge will travel to adjacent towers where part of it will be absorbed by the tower, part will continue on the ground wire, and part will be reflected. Flashovers may occur between the towers and one or more conductors, so that towers, ground wires, and affected conductors will assume the same potential. Flashover also may take place at midspan between conductors and ground wire; the conductor potential then will be of sufficient magnitude to cause an additional flashover at an adjacent tower.

In a well protected, well insulated line a stroke to the ground wire in midspan or to a tower is quickly reduced by reflections from adjacent towers and becomes of very small magnitude three spans distant from the point hit. Calculations indicate that where tower footing resistance is low, insulator flashover is not likely to occur. In all cases where flashovers do not occur either at midspan or at towers, potentials induced on the conductors by coupling will become negligible beyond the region of the disturbance. In such cases no surge will be propagated over the line to terminal apparatus and the line will continue to operate unaffected by the lightning stroke.

Field Tests with Artificial Lightning

High-voltage impulses simulating lightning surges can be impressed on a line at will, and now provide the most convenient means for studying the characteristics of such waves. Corona is found to be the greatest cause of wave attenuation and distortion; to a lesser extent, skin effect.

IN THE first class of field investigation described, high-voltage impulses were impressed upon the line and cathode-ray oscillograms taken at different points along the line. By comparing oscillograms of the original wave with those taken out on the line, information was obtained regarding the general behavior of traveling waves with particular attention given to attenuation and distortion. In the investigation described by Dowell, oscillograms were taken at the point of impulse-generator connection only. These tests were made with an oscillograph having a comparatively slow sweep, the principal object being to determine the effects of reflections.

To obtain the high-voltage surges, a lightning impulse generator designed especially for this class of investigations was used. Both this apparatus and the cathode-ray oscillograph have been described in detail in previously published articles.

Brune and Eaton report upon the results of a test of the first type mentioned which was made jointly by the General Electric Company and the Consumers Power Company (Mich.) on the Croton Dam-Grand Rapids 75-kv. line of the latter company. Line data and other features of these experiments are given in Table II. Because previous sphere-gap tests showed that the rate of attenuation is affected by voltage, polarity, and distribution of the charge over one or more conductors, test wave shapes were chosen to accentuate these features.

FACTORS AFFECTING WAVE PROPAGATION

A group of typical cathode-ray oscillograms replotted to uniform time and voltage scales is shown in Fig. 8. It may be noted that attenuation is much more rapid above corona voltage than below it (the calculated critical corona voltages for this line being 85 and 125 kv. for surges on one and on three parallel conductors, respectively).

These waves support the theory that in the mechanism of corona, as previously outlined, (1) the area surrounding a conductor becomes conducting only within an envelope of limited radius; (2) when the voltage rises above the corona voltage, charges enter the envelope and remain there until the conductor voltage falls, returning then to the conductor and thus holding up and flattening out the tail of the wave. The process can be likened to the discharge of one condenser into another through a resistance, the difference being that on a transmission line the quantities are distributed rather than lumped, and are variable depending upon the voltage.

It may be noted, however, that other factors besides corona appear to affect the propagation of the surges. This is brought out clearly in those oscillograms where the crest voltage is below the critical corona value. Such waves exhibit changes in form which might be caused by line resistance, the general effect observed being a continuous attenuation of the front of the wave, a reduction in crest voltage, and lengthening of the wave tail. This is accounted for by the variable character of the line resistance due to skin effect as explained in another article of this group.

Lewis and Foust attribute the flattening of the wave front and lengthening of the tail to the lower velocity of propagation for the high-voltage portion of the wave, but that such a point of view must not be accepted finally as an explanation of the mechanism of surge propagation without a closer examination than has yet been given. These authors state further that the influences of corona and polarity upon surge propagation have been shown to be great and that both probably are determining factors. Conditions of relative energy loss on the front, crest, and tail of the wave, however, are said to be but little understood, the shift of energy relations within the wave possibly accounting for wave changes which have been demonstrated.

ATTENUATION

Attenuation curves for several tests showing maximum voltage against miles of wave travel are shown in Fig. 9 (Brune and Eaton). The effect of polarity upon attenuation is evident in these curves at once, the positive surges being attenuated more rapidly than the negative surges, especially by corona. In comparing waves *I* and *J* with waves *A* and *B*, it may be noted also that short waves are attenuated more rapidly than are long waves.

To draw a comparison in attenuation between waves on one and on three parallel conductors, respectively, reference is made to curves *C* and *I* (which have approximately the same length at a voltage of about 600 kv.). It may be seen readily that surge *C* attenuates more slowly than surge *I*; the same comparison may be drawn between surges *D* and *J*. It seems obvious, therefore, that a surge on three conductors will attenuate more slowly than a corresponding surge on one conductor. This is in accord with the fact that where the same voltage is applied to three parallel conductors the voltage gradient will be less than around a single conductor. Therefore, the effect of corona (which is considered the greatest single contributing factor) will be less for three conductors than for one.

REFLECTIONS

The experiments described by Dowell were made on the 132-kv. Philo-Canton line of the Ohio Power Company (see Table II). The oscillograph in this case was coupled to the line at the point of connection of the lightning impulse generator. The voltage measured is the sum of the incident and reflected waves, the two components being entirely different in magnitude and shape. Crest voltages of the applied waves were obtained by sphere-gap measurements, and the voltages of successive reflections by comparative deflections on the oscillograms. All waves in these tests were applied to a single line either grounded or open-circuited at the far end. According to Dowell, if the applied wave is of the order of two or more times the length of the transmission line, successive reflections are superposed on one another and the individual waves must be segregated before attenuation constants can be obtained. This segregation was facilitated by use of the lattice diagrams described by Bewley in another part of this symposium.

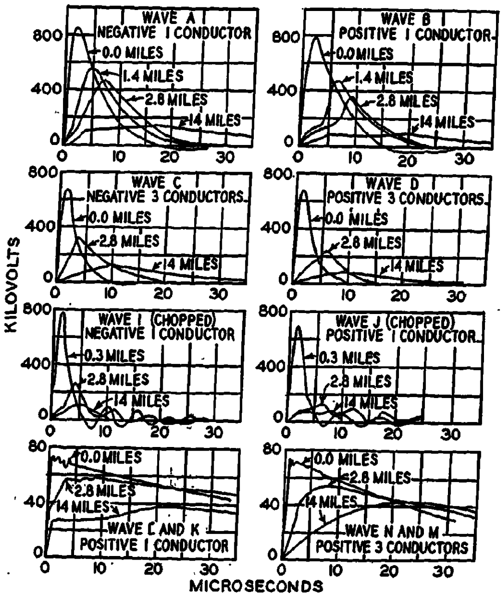

Fig. 8. Typical oscillograms replotted to uniform scales to illustrate change in wave shape with travel along the line

Reflection and refraction operators were derived mathematically for the existing line and terminal conditions. When applied to the function of time representing an incident wave, these operators give respectively the differential equations, the solutions of which are the reflected and refracted waves. This mathematical work was facilitated by the use of Heaviside's operational calculus. Attenuation constants were determined by comparing the calculated values with the oscillogram measurements. This method of attack seems especially applicable to cases wherein the wave of the applied impulse is long enough to permit a reflection to return to the point of measurement before the original wave has completely passed that point.

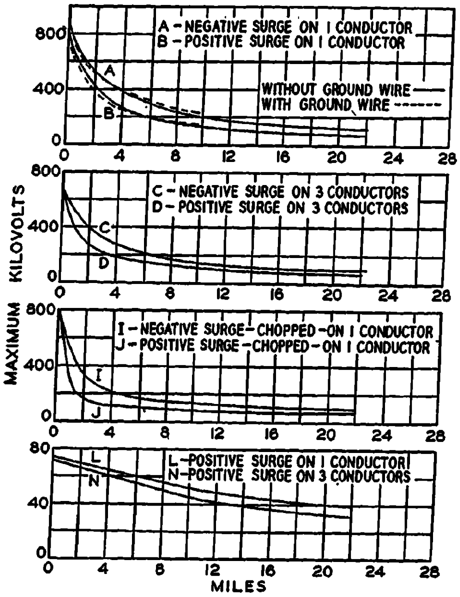

Fig. 9. Reduction in crest voltage of typical traveling waves

A typical lattice diagram for a typical line condition with an oscillogram taken at the lightning generator under the same condition may be seen in Fig. 10. The various crests in the oscillogram show definitely the effects of successive reflections especially at the fifth wave crest where reflections from both ends of the line are superposed.

Discussing attenuation on the basis of his results, Dowell agrees that the principal causes of wave attenuation and distortion are corona and, to a lesser extent, skin effect. However, he states that artificial lightning waves may attenuate considerably without an appreciable change in shape, other than some slowing down of the crest. From these findings it is thought permissible to treat such traveling waves as though the line were distortionless, in which case the attenuation is accounted for by a simple exponential decrement factor. Waves calculated under these conditions check quite closely with oscillogram measurements as may be seen from Fig. 11.

Dowell states further that while the segregation of

Typical comparisons between calculated waves and actual measurements

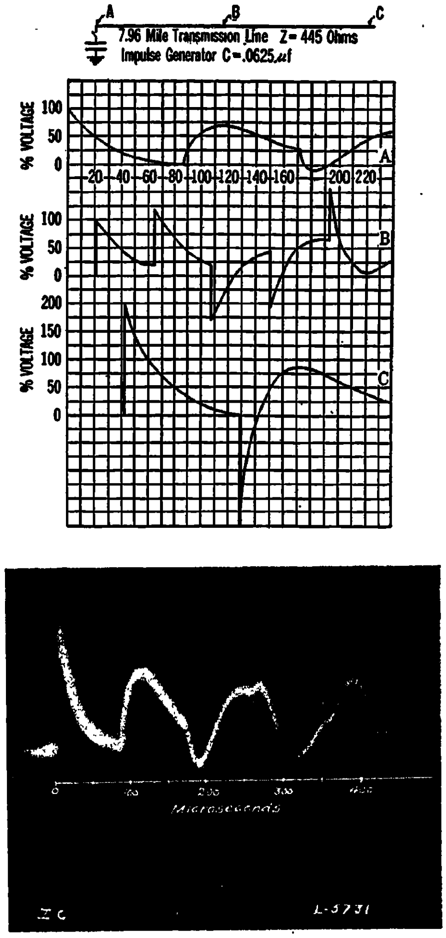

Fig. 11. (Right) Voltage-time relations for traveling wave on line open at one end; (above) computed curves; (below) oscillogram at point A

the attenuation from successive reflections is a long and laborious process subject to errors both in the mathematical and oscillographic work, the calculations demonstrate once more that traveling waves on transmission lines may be computed with excellent engineering accuracy by treating the line as distortionless.

INDUCED VOLTAGES IN PARALLEL CONDUCTORS

The theory of induced surges in parallel conductors developed by K. W. Wagner for the non-dissipative line, leads to a set of simultaneous linear equations expressing surge voltage on any conductor in terms of the surge currents on all the conductors. The usual convention of regarding all voltages as being composed of two traveling waves proceeding in opposite directions is observed. Because of the linear relationships in these equations an induced surge will have exactly the same wave shape as the inducing surge. An isolated conductor will have a potential due to its position in the field, but no current along the conductor.

Sphere-gap measurements of induced voltages made in 1929, however, showed that the ratio of induced to inducing voltages increased as the surge proceeded along the line. Since attenuation was also in evidence it followed that the theory of the non-dissipative line would not hold accurately.

Further light is thrown upon this phenomenon by oscillograms obtained by Brune and Eaton, a selection of which appears in replotted form in Fig. 12. In these oscillograms it may be seen that the wave shapes of induced and inducing surges differ widely. For both positive and negative waves the voltage of induced surge is lower at the beginning and higher later on than that which would be due to the field of the inducing surge alone, while the negative induced surge is actually of opposite polarity at the beginning. This peculiarity in the induced wave cannot be attributed to corona

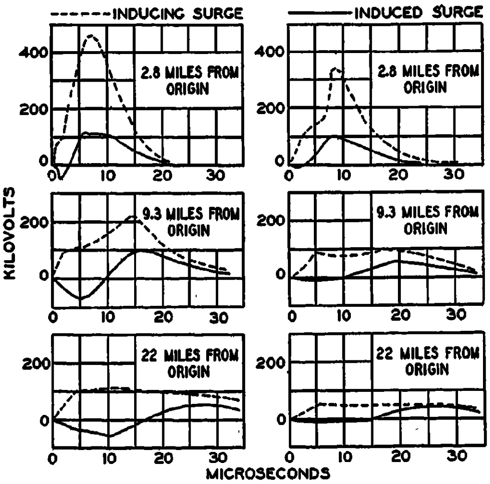

Fig. 12. Replot of induced and inducing surges in free conductor for both negative (left) and positive (right) inducing impulses

effects; the same conditions have been found to exist on surges below the critical corona voltage.

In an attempt to arrive at some conclusion in regard to this effect, Brune and Eaton say that there appears to be a continuous separation of charge taking place within the induced surge. A charge having polarity opposite to that of the main surge is thought to collect in front of the induced surge, thus decreasing the resultant voltage there, while charge of the same polarity increases the voltage in like manner in the latter portion of the induced surge. The mechanism by which this separation takes place is not at all clearly understood, but it seems to be connected in some way with the process of attenuation and distortion of the main wave. Thus it appears that not only is the self-surge impedance no longer a constant for wave propagation on a dissipative line, but also that the mutual surge impedances have become more complicated. This theory would account for the flattening in wave crest noted in Fig. 8, waves *C*, *D*, and *N*.

Field Tests With Natural Lightning

Although lightning surges of as high as 5,000 kv. have been recorded, only about ten per cent of these have crest voltages of more than seven times normal line voltage. One important result of recent investigations is the proof that a direct stroke can occur to a tower or ground wire without causing a flashover.

NATURAL LIGHTNING INVESTIGATIONS, as may be implied, differ from the experiments just related mainly in that the tests and measurements were confined to natural lightning discharges occurring during storm periods, and the resulting line surges. Accordingly the results have been correlated with line flashovers, faults, and general system performance. A few measurements were obtained at points very close to actual direct strokes. The effects of special ground wire construction, tower grounding cables, counterpoises, and various other protective measures were investigated.

Inasmuch as these investigations were conducted for the most part with the lines in operation an opportunity was afforded for evaluating the results in terms of actual operating experience.

TEST EQUIPMENT AND INSTRUMENTS USED

Besides the cathode-ray oscillograph which has found universal application in all lightning surge studies, the klydonograph also has been used to a large extent for making both voltage and current measurements. Surge-voltage recorders, also well known in this class of work, have been used in many cases. The field intensity recorder described in previously published articles also has found some application. Three new devices, developed especially for this sort of investigation and used in some of the more recent tests, are:

1. Direct-stroke recorder.

This instrument consists essentially of a small klydonograph with timing accessories omitted, and is built into an ordinary telephone receiver It usually is coupled directly to the transmission-line tower through a resistance potentiometer. (See Fig. 13)

2. Surge or flashover indicator.

This is a small device which can be applied to each insulator assembly on a tower and is so designed that an indication visible to a ground patrolman will show after a flashover on that assembly has occurred.

3. Storm-severity meter.

This consists essentially of a roll-film box camera containing a special glow tube, the tube being connected between a 30-ft. vertical antenna and ground. Collapse of electric charges collecting on the antenna during storms causes the tube to glow and record a spot on the film; thus the intensity or degree of darkness of this spot is an indicated function of the number of charges on the antenna and their magnitude.

The lines on which these investigations have been carried out are indicated in Table II (see also Fig. 15). Line construction data are given with special features noted; instruments used in each case are listed to give some indication of the scope of each investigation. Unusual features of each investigation are noted also.

The results although sometimes difficult to interpret nevertheless reveal many interesting aspects of the lightning situation and the line protection problem. Wherever possible attempts have been made to correlate system disturbances directly with either direct strokes or induced surges. The inconsistencies which still exist are due partly to an incomplete understanding of the fundamental nature and behavior of lightning, and partly to the widely varying nature of the lightning discharge itself.

DIRECT AND INDUCED STROKES

That effective measures for protection may be adopted, it is necessary first to distinguish between direct and induced strokes, the relative magnitudes of their potentials, and the frequency of occurrence and other characteristics, and then to evaluate these in the light of system performance. That direct strokes to line conductors nearly always cause flashovers and trip-outs, is quite generally agreed; and that direct strokes to ground wires or towers often do also. In-

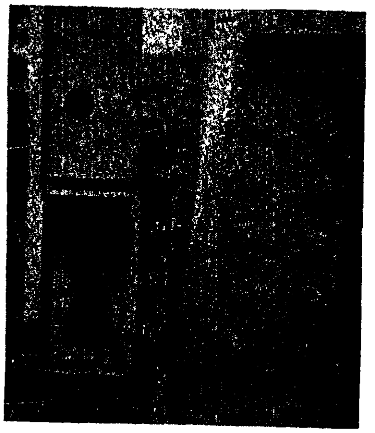

Fig. 13. Direct-stroke recorder installed at base of tower

duced surges, either from cloud discharges unaccompanied by stroke to earth, or from direct strokes to nearby objects, may in some cases be sufficiently high to cause flashovers and line trip-outs. The probability of induced voltages causing line outages is greatly reduced by overhead ground wires, and also depends to a large extent upon tower footing resistance and line insulation.

Bell and Price, in reporting the results of extensive investigations pursued on the 220-kv. transmission system of the Pennsylvania Power & Light Company, state that direct strokes usually contact only one object (ground wire, power conductor, or tower top) and do not fork to other objects (power conductors for instance) in the same vicinity. They also state that voltages induced in the conductors by the collapse of cloud fields do not appear to endanger service over circuits as highly insulated as the lines in question. In their investigation an attempt was made to determine the approximate magnitude of induced surges by measuring the voltage induced in a 100-ft. antenna installed near the line, but not coupled to it. A potential of from 2,700 to 3,150 kv. was measured on this antenna, but the corresponding voltage induced in the line conductor was only about 350 kv. In no case could extremely high voltages measured on the transmission line be correlated with those measured on the antenna.

During this same investigation an oscillogram was obtained of a direct stroke of negative polarity which occurred not more than 500 ft. from the lightning laboratory and which caused a trip-out and single-phase fault. This oscillogram is shown in Fig. 16. As may be noted, the voltage rise was rather gradual for the first 3.5 microsec., but was quite rapid during the next 2 microsec., until the insulator flashed over on the crest of the wave at a potential of more than 2,760-kv., the maximum range of the oscillograph.

Another interesting record of a direct stroke is that obtained by Gross and Cox. (Fig. 17.) This represents a klydonograph record, simultaneous records being obtained by both the direct-stroke recorders and cathode-ray oscillograph. The line (Turner-Logan) tripped out three times within 20 minutes during this storm, but the only flashover which could be located by inspection after the storm, was on the top phase of the tower adjacent to that at which the klydonogram was obtained.

Fig. 14. Circuit diagram for a "double-sweep" cathode-ray oscillograph

Two cases are reported by Sporn and Lloyd wherein trees were struck at points quite near the line. In one case two trees respectively 500 and 1,500 ft. from the line were struck. The nearest surge-voltage recorder (more than a mile away) indicated two highly damped surges of −4.8 and +2.4 times normal voltage, but it was impossible to correlate either stroke with a line trip-out or even a flashover. By a peculiar coincidence another tree at this same point had been struck previously. This tree was 360 ft. from the line and near the 500-ft. tree mentioned in the other case. At that time the surge recorder (located at an adjacent tower) indicated a positive maximum voltage of 2,100 kv. A trip-out occurred apparently caused by the high voltage induced from the direct stroke to the tree. These two cases well illustrate some of the inconsistencies encountered.

Lewis and Foust comment on the question of direct and induced strokes as follows:

"Apparently there is evidence to the effect that direct strokes play an important part in transmission flashovers and outages. There is a great deal of evidence that induced strokes also are highly important. There is insufficient evidence at the present time to evaluate more exactly these two types of strokes."

CREST VALUES OF LIGHTNING SURGES

As might be expected the crest values of lightning voltages and currents are subject to many variations also. Bell and Price report a maximum voltage well above 3,000 kv. (see Fig. 16) measured at a point not more than 500 ft. from the stroke. Currents from less than 40,000 to about 260,000 amperes are indicated in their report.

Voltage measurements from a 4-year study are plotted by Gross and Cox as shown in Fig. 18. Voltages of surges due to switching also are shown in this diagram. The maximum lightning voltage recorded was about 26 times normal, or 2,800 kv. It may be noted that only 10 per cent of the surges were of more than seven times normal line voltage. It has been computed also that the lines involved in this investigation (Appalachian Electric Power Company) are subject to 4.6 lightning voltages of 15 times normal per 100 mi. of line per year. Compared to other published data this would show that the lines in this territory are subjected to lightning disturbances of greater than average severity.

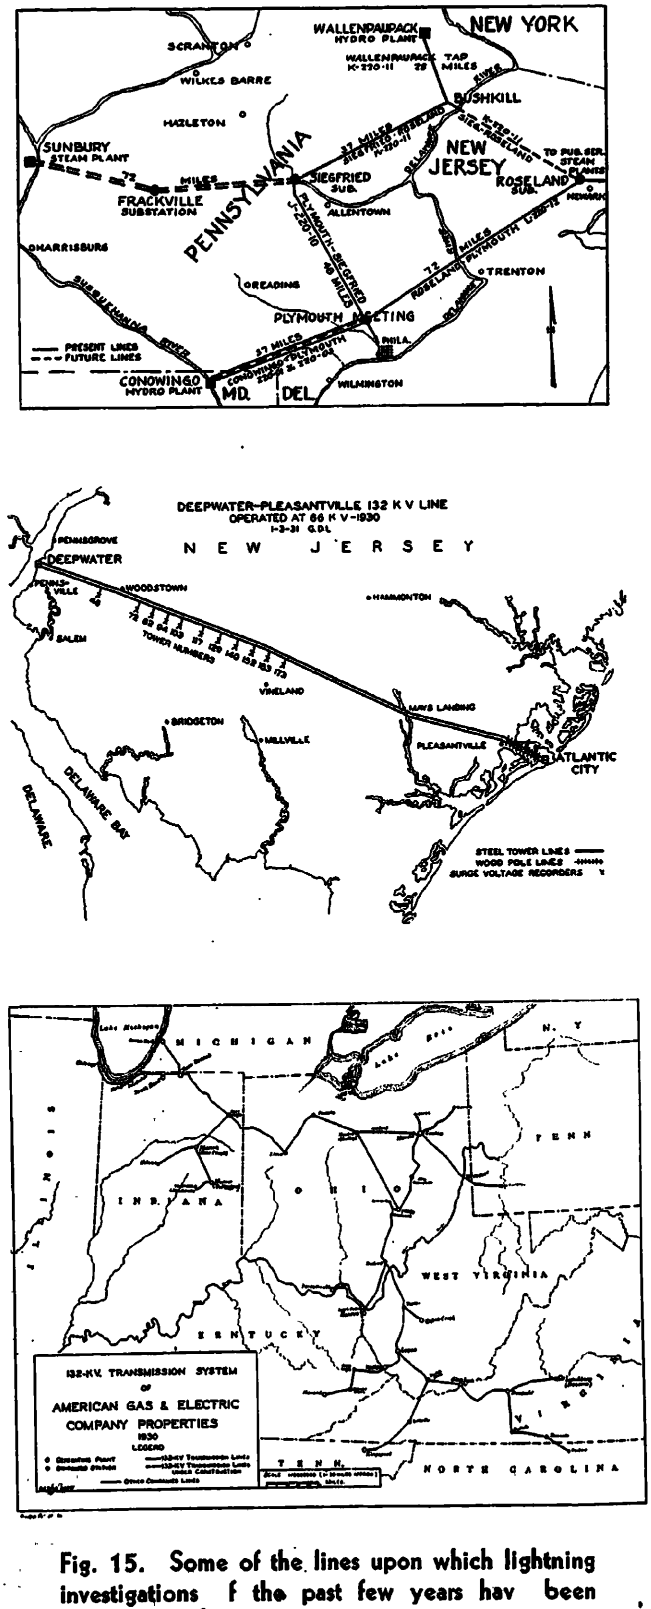

Fig. 15. Some of the lines upon which lightning investigations of the past few years have been concentrated

In the same investigation similar results were obtained for lightning voltages appearing at substations. In this case the highest lightning voltage recorded was only twelve times normal while only 4.5 per cent were more than seven times normal. This reduction is attributed to the lightning arrester protection installed at substations and also to the number of paths into which an incoming surge can be dissipated.

Sporn and Lloyd report a maximum lightning voltage obtained (Philo-Canton line—1930) by surge recorders of only 6.5 times normal (700 kv.). The low severity of lightning storms during that year in that section of the country is believed to be the reason for the absence of higher voltage measurements. Discharge currents of from 40,000 to 670,000 amperes were indicated, however, (by adding the tower currents), the current distribution for a typical case being shown in Fig. 19. These values are subject to a certain amount of error because of the fact that all currents may not have been recorded simultaneously. Reflections at points of changing surge impedance also would affect the measurements.

Lewis and Foust have plotted (see Fig. 20) the results of lightning voltage as measured by surge-voltage recorders based on a study of 678 lightning surges occurring on fourteen systems during the years 1926-1930 inclusive. Voltages due to switching are shown also, based upon 724 surges occurring during the years 1927-1930 inclusive on practically the same systems from which the lightning data were taken. These curves are in close agreement with those obtained by Gross and Cox.

All of the results mentioned so far have been concerned with lines having steel supporting structures.

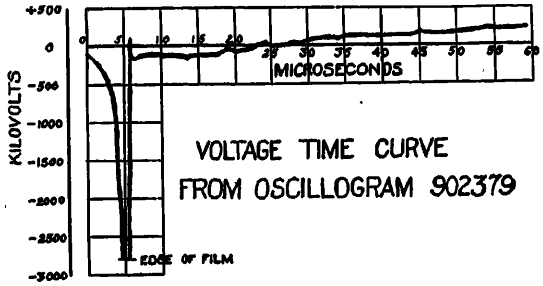

Fig. 16. Oscillogram of a direct stroke taken about 500 ft. from point of stroke and 125 ft. from insulator flashover; flashover occurred also at an adjacent tower and was followed by a line trip-out

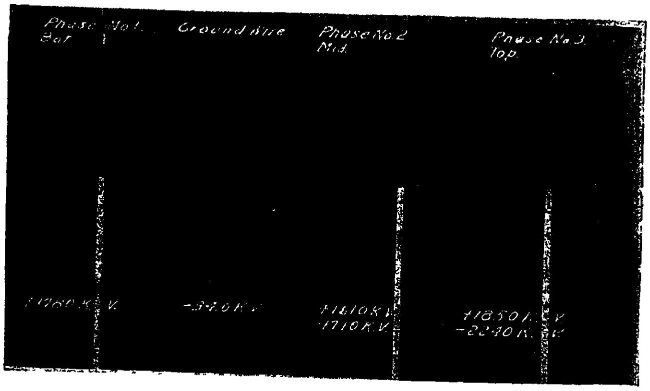

Fig. 17. Klydonograph record of a lightning surge

Negative surges are indicated on ground wire and two top conductors; positive surges are in evidence on all line conductors. A simultaneous cathode-ray oscillogram showed the disturbance to b oscillatory. (Important details of klydonograph records are unavoidably lost in reproduction.)

Much higher voltages due to lightning have been reported by Pittman and Torok in their tests on the Camden-Magnolia (Ark.) 110-kv. wood-pole line. On this line pole-grounding wires are installed only on guyed structures which normally are about one mile apart. The maximum voltage recorded in the investigation was approximately 5,000 kv. measured at a point about 4 mi. from the point of stroke (see Fig. 21). The indicated rate of potential rise is about 4,000 kv. per microsec. These values contrast sharply with the maximum reported on steel-tower lines. It appears quite obvious that the voltage of the discharge if measured at the point of incidence would have been much higher than the voltage measured 4 mi. distant, although the actual maximum value is a matter of interesting speculation.

An examination of the surroundings near the point of discharge of this bolt showed that an arc had been established from a line conductor to a telephone wire crossing 22 ft. below the line. In addition both 50-ft. poles on the H-frame supporting structure adjacent to the telephone line crossing were splintered. Allowing 350 kv. per ft. as the breakdown strength of air, a potential of 7,500 kv. would be required to flash from conductor to telephone line. However, since corona loss at such high voltages is tremendously high, it is quite obvious that a 2,500-kv. difference is not sufficient to account for the voltage lost in 4 mi. of travel. These facts would tend to place the voltage of the original stroke at a value somewhat higher than 7,500 kv.

FLASHOVERS AND TRIP-OUTS

Of the 65 line insulator assemblies flashed on the 220-kv. Wallenpaupack-Siegfried line, Bell and Price report that 71 per cent showed glaze burns characteristic of dynamic arcs. Of 38 flashover indicator operations, 29 (76 per cent) were associated with marked insulator assemblies. Most of these flashovers occurred on phase conductors occupying the outer positions on the towers. Some 24 trip-outs were associated with the 65 flashovers most of these being accompanied by single-phase faults. Their results show in addition that 32 flashovers out of 36 involved only one phase, but that in 15 of these 32 more than one insulator assembly was flashed over.

Gross and Cox state that of the surges higher than 600 kv. recorded in their investigation, thirteen were associated with line trip-outs while ten were not. They account for the existence of high-voltage surges (higher than the 60-cycle line flashover voltage) without flashover and trip-out by the fact that when a direct hit to a tower occurs the tower potential is altered with respect to ground because of its surge impedance and footing resistance; although the voltage to ground may be higher than the line flashover value the voltage between line and tower may be somewhat less. This explanation, however, does not account for the absence of trip-outs in all cases, and it is believed consequently that lightning flashovers sometimes may occur without subsequent power arc and line outage.

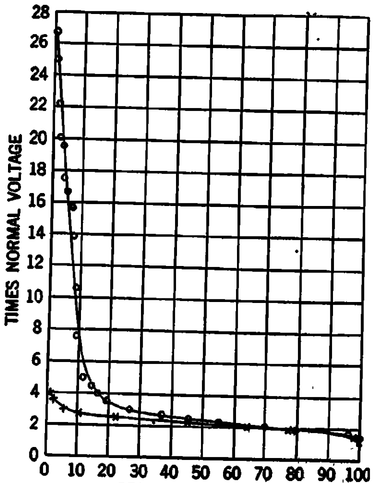

Fig. 18. Surge voltages reported by Gross and Cox for the period 1927-30 inclusive (based upon 143 lightning and 98 switching surges)

In attempting to correlate these trip-outs with tower footing resistance and line elevation, these authors definitely state that, "an attempt to relate line flashovers to tower footing resistance proved futile." As regards tower elevation, there was some tendency for flashovers to concentrate near high points in the line contour, which experience is in accord with the reasonable expectation that lightning will strike the most exposed points; these, of course, being the points of highest elevation.

In the results obtained by Sporn and Lloyd during 1930 on the Deepwater-Pleasantville 132-kv. line, twelve direct strokes were recorded, only three of which could have resulted possibly in a trip-out, while on the 30-mi. section of the Philo-Canton line thirteen direct strokes were recorded, only one of which possibly could have produced a trip-out. Of a total of 107 surges recorded in Ohio only 33 per cent were due to lightning, 60 per cent being due to switching. Notwithstanding the many surges recorded, only four trip-outs occurred, three of which involved both circuits. There were indications, however, that flashovers had occurred in some cases where trip-outs had not.

Pittman and Torok state that on the wood pole line upon which their investigations were made, voltages as high as 2,000 kv. were recorded without any switch operation. This was not thought particularly surprising since the line was equipped with several drain points set to operate at about that voltage. General experiences on this line have pointed to the conclusions that voltages of a harmful character occur only when direct strokes or their branches terminate on the conductors, and that trip-outs on ungrounded wood pole construction usually result from phase-to-phase flashovers.

Lewis and Foust outline three conditions under which line insulation may flash over as a result of direct strokes. They are (1) a stroke to line conductor, (2) a stroke to the tower, and (3) a stroke to the ground wire between towers where the potential is such that flashover will occur between ground wire and line conductor. Direct strokes to line conductors appear to be of rare occurrence where steel towers and overhead ground wires are used. Where insulator flashover does occur under these conditions, it apparently results through high tower potentials caused by high footing resistance.

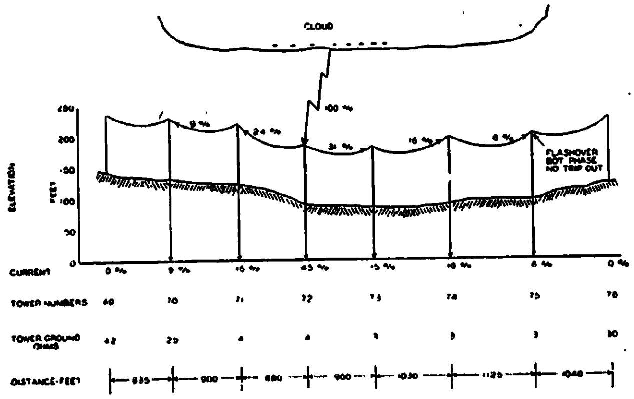

Fig. 19. Typical lightning current distribution on either side of a struck tower

It is further stated that where flashover does occur from tower to conductor the spread to other insulator assemblies on the same tower may be prevented by the resulting reduced impedance between tower and ground. Experience has shown also that a flashover is not necessarily followed by a line trip-out. A permanent arc is not set up because the power voltage to ground and conductor current do not have sufficient amplitude and proper polarity relations to establish it.

Extent of System Affected

The extent to which a transmission system may be affected by lightning discharges appears to depend mainly upon line design and insulation; also upon whether or not flashover occurs at or near the point of incidence. On steel-tower lines where flashover occurs, experience has shown that the disturbance is limited to five or six adjacent towers, flashover in most cases occurring on one phase only, but in many cases on two insulator assemblies at adjacent towers.

Fortescue and Conwell state that if a tower or ground wire is struck and no flashover results, severe electrical disturbance is limited to a few structures, and any surge propagated over a conductor will be of extremely low magnitude. They also agree that disturbances on tower and ground-wire systems usually are limited to approximately six spans, where tower footing resistances are low. Potentials induced on the conductor arising from such surges on the ground wires become nil beyond the region of the disturbance. Thus no surge on the conductor can be propagated beyond this region unless flashover takes place.

In addition to the foregoing, Fortescue and Conwell discuss in some detail the effect of line construction on surges propagated over the lines to substations. It is finally concluded that ordinarily with only one type of construction, namely, ungrounded wood pole, will the potentials be sufficiently high to endanger substation equipment. Pittman and Torok's results agree with the fourth case just described in that voltages of high magnitude may be transmitted for several miles along highly insulated transmission lines and thus appear at terminal apparatus. This is true especially when direct strokes or their branches terminate on line conductors.

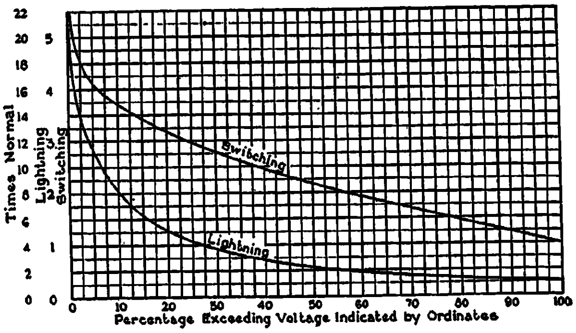

Fig. 20. Surge voltage curves compiled by Lewis and Foust based upon data from fourteen systems for the years 1926-30 inclusive

GROUND WIRES AND TOWER FOOTING RESISTANCE

"That a direct stroke could occur to the line without producing a trip-out" is said by Sporn and Lloyd to be one of the outstanding determinations of the 1930 lightning investigation and is believed to be due to the protection offered by the overhead ground wire in diverting the stroke to ground. In regard to tower footing resistance they continue that "the better showing in Ohio was probably due to the lower average tower ground resistance in Ohio, mostly less than 10 ohms against one-third of more than 50 ohms in New Jersey."

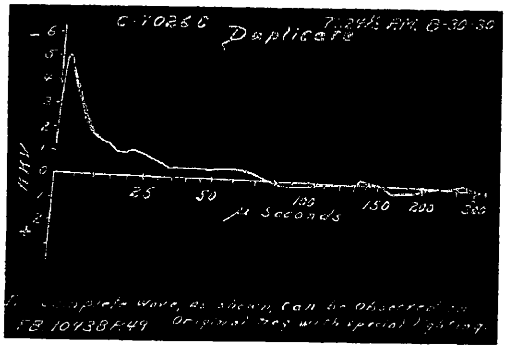

Fig. 21. 5,000-kv. surge measured 4 miles from point of stroke

All three phases flashed to ground splitting the wood-pole supporting structure and causing a circuit breaker operation. Also center conductor flashed 22 ft. to a telephone line at a crossing 3,600 ft. from the stroke

Data obtained in these field investigations have established without question the effectiveness of the conventional ground wire for protecting lines against lightning disturbances. In general it has been found that only in rare cases will a line conductor be struck when steel tower construction with conventional ground wires are used. The results show in addition that from two to three times as many interruptions occur due to lightning on lines without ground wires as occur on lines with ground wires installed.

It is reported by Lewis and Foust that out of 231 total interruptions on the transmission system of the Public Service Electric & Gas Company (New Jersey), only six have occurred on 66- and 132-kv. lines where overhead ground wires are installed. Mention is made also of a 14-mi. 66-kv. double-circuit steel-tower line operated by the Philadelphia Electric Company which is equipped with two ground wires, one placed vertically over each of the outermost conductors. This line has not experienced an outage due to lightning in fourteen years. The beneficial effect of low tower footing resistance also is well emphasized in this case since the resistances are all unusually low and uniform, being of the order of 4 ohms each. In this connection Fortescue and Conwell, speaking of the 220-kv. lines of the Public Service Electric & Gas Company, state that "during one year's investigation on lines equipped with ground wires, no flashovers have occurred where tower footing resistances are less than 5 ohms."

A direct comparison between lines with and without ground wires has been obtained by Bell and Price. This comparison is illustrated in Fig. 22, where the number of flashed insulators per tower per year has been plotted against tower footing resistance for each case. The effect of ground wires appears to be to reduce the number of flashovers to about 15 per cent of those which otherwise would occur. The effect of tower footing resistance at least above 17 ohms seems to be negligible in this case.

Some difference of opinon appears regarding the benefits of low tower footing resistance. It is quite generally agreed, however, that extremely low resistances (only a few ohms) do show a marked beneficial effect.

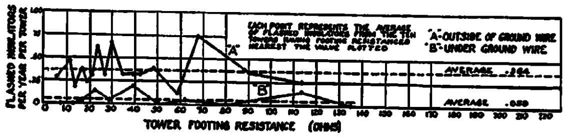

Fig. 22. Effects of tower footing resistance and overhead ground wires on insulator flashovers occurring on a 220-kv. line section

WAVE SHAPES

According to Lewis and Foust, oscillographic work on transmission lines under natural lightning conditions has shown that waves to be expected on transmission lines vary in time to crest from about 1 microsec. to several hundred, but that the tail of the wave extends over a much wider range. In general the lower voltage surges appear to be of longer time duration.

Wave shapes measured at or near the origin of surges have fronts which bring the conductor potential up to flashover values in the order of about 1 microsec. These high-amplitude waves of steep front usually cause flashovers and therefore are reduced quickly to low potential values. Apparently voltage waves rising to fairly high values, but still under insulator assembly flashover value, would possess a longer time to crest and also a wave tail of at least some 10 to 100 microsec. in length.

Wave fronts rising at the rate of from 1,000 to 2,500 kv. per microsec. have been measured in several cases, but Pittman and Torok in their test on a wood pole line found that surges at the point of origin may have a rate of rise of 4,000 kv. or more per microsec.

Sporn and Lloyd present curves showing approximate wave shapes for the maximum, minimum, and average wavelengths observed on 29 oscillograms recording 50 kv. on crest or higher, and therefore not causing flashovers (see Fig. 23). Wave shapes for higher voltage surges where flashover occurred are shown in other illustrations.

Bell and Price state that among other things the wave forms of lightning surges appear to be dependent upon whether the surge originated and created fault on the phase to which the oscillograph is connected, or on either or both of the other two phases.

Gross and Cox in speaking of attenuation agree that attenuation is greater for positive than for negative surges. They assert further that attenuation of high-voltage surges is very rapid, maximum crest values in the order of 2,000 kv. being reduced to one-half that value within about a mile. An empirical formula has been developed from actual measurements by which the voltage reduction or attenuation can be determined for any point on the line. This is illustrated in Fig. 24. This formula contains constants which depend upon the characteristics of the line under consideration, and agrees fairly well with results of attenuation studies where artificial lightning has been used.

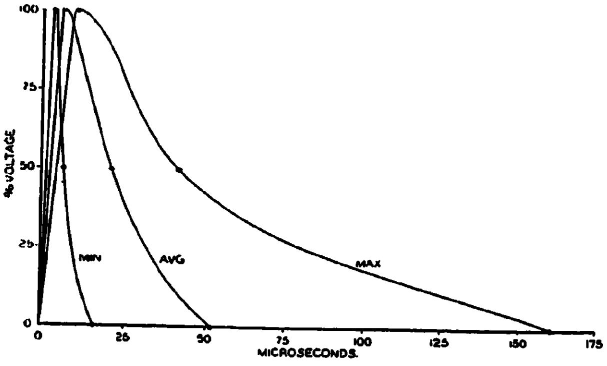

Fig. 23. Empirical wave shapes of lightning surges showing envelopes for maximum, minimum, and average time relations

Wave shape and attenuation studies of natural lightning discharges in general agree fairly well with the results of theoretical studies outlined previously, but in any case the wave shape of a particular surge appears to depend upon (1) whether the surge results from a direct stroke or is induced, (2) polarity, and (3) whether or not flashover takes place.

POLARITY

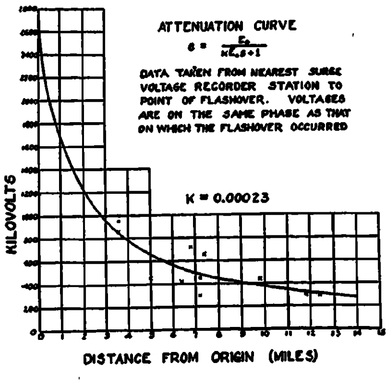
Some difference of opinion exists regarding the polarity of lightning discharges as evidenced by excerpts presented herewith. Bell and Price state that most lightning strokes are of negative polarity, as indicated by measured structure currents. Smaller proportions appear to be oscillatory with negative polarity predominating. Positive surge voltages between conductor and tower usually are indicated at locations where a ground wire or conductor not coupled to the surge voltage recorder is contacted by direct strokes. These therefore are not indications of induced surges due to cloud fields.

Gross and Cox report that 60 per cent of the conductor surges measured by them were negative, 40 per cent positive. Of the ground-wire surge voltages investigated, 70 per cent were positive, 21.5 per cent negative, 8.5 per cent oscillatory.

Sporn and Lloyd found that lightning surges were positive ten times as often as negative, but that each of the stroke recorder charts indicated the cloud to be negative. These authors advance the belief that overhead ground wires prevent the majority of negative lightning bolts from reaching phase wires and that, therefore, positive surges measured on the lines are due to induction.

Lewis and Foust state that measurements of cloud field potentials have established beyond question that fields of both polarities are present, and that field polarity at a point on the ground may change from positive to negative or from negative to positive during storm. Additional statements made by these authors, however, are to the effect that all lightning stroke recorder charts of direct strokes to tower indicate the tower to be negative. From this it is inferred that clouds are negative and the ground positive. With the tower structure positive with respect to the cloud, breakdown proceeds from structure to negative cloud, and the strokes terminate on the grounded structure under this polarity condition. Should the tower structure become negative with respect to clouds, strokes would proceed from the cloud, and the probability of the tower being struck would not be great. While this conception appears to reverse the accepted picture of cloud-to-ground strokes, nevertheless it is said to be consistent by being in accord with laboratory and field experience.

Fig. 24. Attenuation curve and formula determined empirically from surge-voltage recorder data



Protection Against Lightning Surges

Requirements for a "lightning proof" line, where this seems justified economically, are outlined in this article. Insulation alone is not the final answer, only one of several important features of proper line design. A new arrester of the gap type is described also, wherein the breakdown medium is a column of air.

INSULATION FAILURES arising from lightning discharges are shown by experience to be the cause of a majority of transmission line outages. It is highly desirable, therefore, that protective measures be adopted and practical protective devices be installed to reduce the number and seriousness of such disturbances. That it is impractical to over-insulate a line sufficiently to withstand lightning voltages is substantiated by records which show that sometimes even on wood pole lines there are impressed surge potentials of sufficient magnitude to flash over the wooden structures to ground.

OVERHEAD GROUND WIRES

The effectiveness of conventional overhead ground wires for lightning protection where steel tower construction is used has been well emphasized by the investigations covered in other articles of this group. For ground wires to be most effective, however, according to general consensus of opinion tower footing resistances should not exceed 4 or 5 ohms.

So-called diverting wires have been experimented with on operating lines. These are special ground wires which may or may not be insulated from tower structures, and which generally are located at a greater distance above the line conductors than are the conventional ground wires. One form of diverter-wire construction is shown in Fig. 25; Peek suggests the possible effectiveness of other forms. According to Lewis and Foust, where such wires are supported on the line towers the only advantage appears to be that due to the increased height of these wires whereas when insulated from the tower structure and provided with independent grounds of low resistance, they possess the distinct advantage of keeping lightning currents out of tower structures. Protection offered by conventional ground wires, however, is said to be such that only in cases of high tower footing resistances do diverting wires appear feasible.

TOWER GROUNDING AND COUNTERPOISES

Where tower footing resistance is too high for efficient ground-wire protection the resistance can be lowered materially by installing buried wires or cables connected directly to the tower legs. These wires may be either extended out radially from the tower or directly from tower to tower along the line. According to Peek radial wires of moderate length usually should be most effective; when installed in this way they are called counterpoises.

Investigations have been made recently to determine the effectiveness of counterpoise in reducing the surge impedance of a tower and thus increasing the effectiveness of the overhead ground wires. On this subject, tests made by Brune and Eaton using artificial lightning discharges revealed valuable information which will be outlined briefly in the following paragraphs.

Theoretically the counterpoise will tend to reduce tower footing voltages both by increasing the capacitance to ground (ground potential assumed to be at an appreciable depth below ground level) and by allowing leakage of charges from towers into the earth. On surge voltages, however, the time element enters in causing the counterpoise to behave like a line with a very high "leakance." Thus reflections may occur from the remote ends of the counterpoise cables and may make themselves felt at the tower footing ends.

For test purposes a tower location was selected where footing resistance measured at 50 cycles was rather high (400 ohms). Various arrangements of counterpoise were connected and surges discharged directly from the line into this grounding system. A probe was driven into the ground about 40 ft. away from the tower and the voltage was measured between that probe and the point at which the line was grounded. In some tests the line was grounded through a known resistance, the voltage across the resistance being taken as a measure of ground current.

Results of the first test are depicted in Fig. 26 where the curves show tower footing voltage for different lengths of counterpoise. As may be noted, extending the counterpoise in two directions produces practically double the effect of extending it in one direction only, but there is no great advantage apparent in extending it further than 1,000 ft. Since this distance in most cases would be more than a full span length the counterpoise in reality would involve at least two spans. How much shorter than 1,000 ft. the counterpoise may be made and still be effective will depend upon the length of surge to be expected and particularly upon the length of the wave front. Counterpoise can be made much more effective by extending in more than two directions, but right-of-way limitations in most cases would constitute a practical obstacle to this.

Additional tests show that current and voltage relations in a counterpoise are not proportional. This fact emphasizes again the non-constant nature of surge impedance. It has been found also that for long wave-fronts the effectiveness of a counterpoise is greater than for short ones. For a surge of approximately rectangular front such as might arise from a direct stroke to a tower, "leakance" of the counterpoise would have no effect initially; only its resistance functioning to limit the tower voltage. This is of considerable importance since with direct strokes the counterpoise to be effective must lower the tower footing impedance to such a value that the tower potential cannot rise to the flashover point.

INFLUENCE OF LINE DESIGN

The influence of line design constitutes another phase of the lightning situation which has been investigated to some extent. The importance of low surge impedance for the grounded supporting structure of a line has been duly emphasized and needs no further mention here. Certain other features, however, play an important part in determining how a certain line will react toward lightning disturbances.

First and foremost it is important that, if possible, line structures be kept clear of high elevations since lightning has a natural tendency to strike the highest object within its range. Where lines must be run over high ground, trees adjacent to the right-of-way will provide some protection. It is desirable also that span lengths be kept as short as possible so that reflections (which have a tendency to reduce the tail of the wave) will return to the point struck in the shortest possible time and thus tend to shorten the wave.

As previously brought out, where high tower footing resistance cannot be avoided, special overhead ground-wire construction or diverters may be employed. Where the economics of the situation will permit, these may be placed in such a way that they will shield the line from direct lightning strokes.

Peek has devoted a great deal of attention to proper line design as regards lightning protection. From the results of his studies he concludes that a "lightning-proof" line for almost any voltage seems feasible. The general requirements for such a line are (1) low elevation, (2) short spans, (3) low tower footing resistance, (4) ground wires, special ground-wire constructions or lightning diverters where tower footing resistances are high, and (5) highly insulated conductors (using from 14 to 16 disk insulator units as is customary on the present 220-kv. lines).

LIGHTNING ARRESTERS AND GAPS

The desirability of lightning arresters for protecting terminal equipment in substations is recognized generally. Lightning arresters also are finding some application on transmission lines, especially where provision for ground wires is not easily made. Arresters possess the distinct advantage of being easily placed at just the points where the protection is desired. Their most distinct disadvantage lies in the fact that

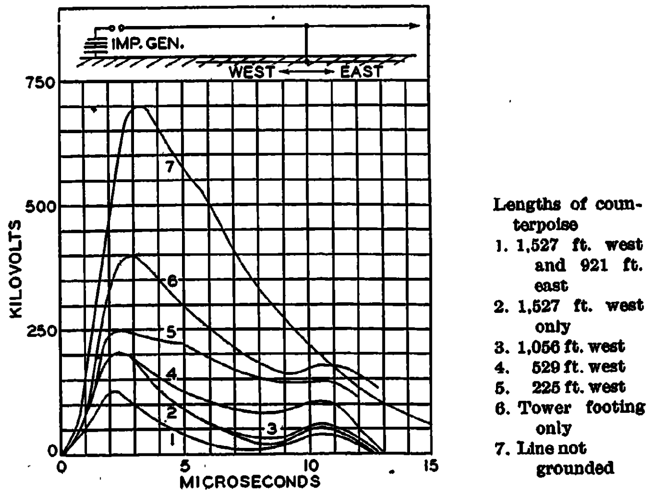

Fig. 26. Surge voltages at point of grounding for various lengths of counterpoise

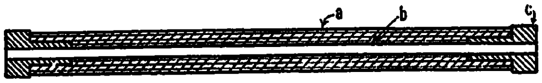

Fig. 27. Section of air-breakdown expulsion-type lightning arrester

(*a*) Fiber tube (*b*) Arc chamber (*c*) Metal electrode

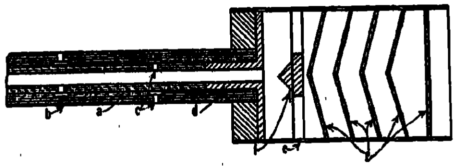

Fig. 28. Section of deionizing chamber for ends of expulsion arrester

(*a*) Inner fiber tube, (*b*) outer fiber tube, (*c*) gas vent, (*d*) electrode, (*e*) steel shell, (*f*) flame spreader, (*g*) perforated baffles their protective effect does not extend more than 500 ft. from the points of application. This feature may prevent arresters coming into general use on transmission lines.

In general, lightning arresters may be grouped into two classes: (1) those which have valve action, acting as good conductors when the voltage rises to a definite predetermined value and as insulators when the voltage drops below some lower value; and (2) those which become good conductors when the voltage reaches a definite value and continue to pass current until the zero point of the current cycle is reached. Familiar examples of the first class are the so-called Thyrite and oxide-film arresters. Familiar examples of the second type are gap devices, both fused and non-fused, of which there are several designs.

Devices of the latter type, consisting of fused horn-gaps, were in use on the 110-kv. wood pole line on which Pittman and Torok conducted their tests. These devices were expected to discharge current incident to lightning surges, and to interrupt subsequent 60-cycle power currents sufficiently promptly to prevent oil circuit breaker operation. In thirteen distinct operations, each resulting in blown fuses, a total of six flashovers occurred, none of which caused a switch operation. In one case, however, a three-phase short circuit resulted from a 5,000-kv. surge which arose from a direct stroke to the line. Details of this event appear elsewhere in this symposium (see Fig. 21). All three fuses in the nearest horn-gap device (about one-half mile away) were found blown, but this did not prevent a switch operation. These results support the previous statement that the protective effect of such a drain point does not extend very far beyond the point of application, even where lines are as highly insulated as this one. Moreover a single fuse seemed inadequate because many flashes of lightning are made up of several successive discharges following each other at very short time intervals, and because after a single fuse has blown no protection is afforded against additional strokes.

A multiple-fuse device accordingly was installed at six locations providing three fuses so arranged that they would blow successively upon the occurrence of lightning surges of sufficient magnitude to cause the gap to flash over. Results were fairly satisfactory, but the necessary continuous patroling and replacement made the arrangement unattractive economically.

AN INSULATOR PROTECTOR

An expulsion type of arrester then was developed consisting essentially of a fiber tube 38 in. long with a wire electrode in each end to reduce the effective arcing length to 30 in., insuring breakdown within the tube. This device was inserted without additional gaps into the line hardware grounding lead. Although these devices have been in use only a comparatively short time they have proved quite satisfactory; eight successful operations have been recorded.

Torok describes in detail some of the difficulties encountered in the development of this device. Some difficulty was encountered in devising assemblies in which breakdown within the tube could be assured. A most promising arrangement was found to be that in which the ratio of internal to external spacing was not greater than 0.85 (see Fig. 27). Some difficulty was experienced also in obtaining proper wall thickness of the tube, since repeated flashovers sometimes caused tube breakdown either by splitting or by puncturing.

In regard to its interrupting characteristics, Torok explains that with an arc established in a cylindrical hole a much higher voltage may be interrupted than if the arc is drawn in the open. If the hole is too small, however, only relatively small currents can be discharged through it. Slepian has shown that the effectiveness of a confining chamber can be increased many times by the use of a material which will produce a gas. With such material the heat of the arc volatilizes the surface of the walls at a rapid rate forcing into the arc stream an appreciable quantity of un-ionized gas. This gas greatly raises the arc voltage and the voltage which can be interrupted. In experimental installations the pressure developed within the tubes by the evolution of gas introduced mechanical difficulties which had to be overcome.

DEIONIZING PRINCIPLES APPLIED

In addition to the mechanical difficulties involved, these tubes often flashed over on the outside because of the convection of ionized gases arising from sparkovers. Deionizing chambers attached to the ends of the tubes have been successful in controlling this condition. The deion principles already have been widely described; the mechanics of this particular application are indicated in Fig. 28.

In designing this tube-type arrester for use on any particular voltage it is essential that the impulse breakdown of the tube be lower than the flashover voltage of the line insulation. Since the breakdown voltage of the tube is governed almost entirely by its length, the maximum internal separation of the electrodes is definitely fixed. The design problem then devolves into one of providing the tube strength required to interrupt arcs normally maintained by the system voltage. For low-voltage protection the design becomes more simple since tube lengths are short and the internal diameters can be reduced without creating dangerously high pressures.

Although still in the experimental stage, development work on this insulator protector is being pushed forward rapidly. It is expected that a practical device which is simple in construction, easy to install, and capable of repeated operation without attention eventually will result.

Lightning versus System Operation

Operating experiences form the final proving ground of the many theories developed; the efficiency of any scheme of protection may be ascertained accordingly. Although one overhead ground wire already is known to be highly beneficial, two are shown to be unquestionably better. Opinions conflict as to the effect of tower footing resistance.

ACCORDING to Sporn's previously mentioned division of the lightning problem as it affects the operation of electric systems, the third part consists of practical operating records covering actual operating experiences where devices and designs for the mitigation of lightning damage are in use. This field experience properly analyzed and interpreted gives the final answer as to the tenability of the many theories developed in connection with lightning and as to the practicability of methods or structures devised to eliminate harmful lightning effects.

Of necessity some of the previous sections of this symposiac have included material which can be classed as operating results. It would be difficult for instance to separate out such results obtained in field investigations of natural lightning where these have been carried on with the lines in operation. Sporn, however, has presented the results of a study made entirely upon the basis of operating records and data and has arrived at certain conclusions based upon the analysis and correlation of those data. This study is a continuation of similar studies made on the transmission system of the American Gas and Electric Company; the data, which were collected in 1929, have been analyzed in the light of previous experiences.

The transmission systems studied have been described in detail in previously published articles. With the exception of a few recent additions the system now comprises 1,198 mi. of 132-kv. lines involving a total of 1,825 circuit miles. It extends from the southern tip of Lake Michigan, southeasterly across the country into northern North Carolina, covering parts of ten states. With one minor exception all lines within the range of observation are of double-circuit steel tower construction with conductors in vertical configuration; all utilize A. C. S. R. conductors, (with a single ground wire of the same material) supported by ten disk units in suspension and twelve on dead ends. Practically all lines are equipped with some sort of arcing protection for insulator strings.

During 1929, 652 observed storms were reported by stations scattered throughout the system. Of these some 565 occurred during the period from April to August inclusive. Recorded lightning outages for the entire system amounted to 133 in 1928 and 248 in 1929. The increase, while due partly to an increase in miles of transmission lines, is attributed largely to the more severe lightning storms which occurred in the region during 1929. A thorough analysis of the operating records and experiences made and interpreted in the light of previous lightning experience on the same system can be summarized as follows:

SUMMARY OF SPORN'S RESULTS

1. Two-circuit lines are better than single-circuit lines.

When installed in vertical configuration on the same towers, the use of two-circuit lines enhances system reliability to proportions greater than does the mere doubling of the circuits. Experience indicates definitely that only from 16 to 29.5 per cent of the trip-outs involve both circuits, and it is likely that this percentage can be reduced by higher speed switching.

2. One ground wire is good; two are better.

The only line equipped with two ground wires had 3.6 outages per 100 mi. of line per year; the only line not equipped with a ground wire had an outage record of 75. A line operating in 1929 with one ground wire had 37.4 outages per 100 mi. of line per year; operating in 1928 with no ground wire this line had the 1929 equivalent of 59.3 outages per 100 mi. of line. This clearly shows the benefits of one ground wire, and definitely indicates that two ground wires are more beneficial than one.

3. Grading shields protect insulators only.

Grading shields have little effect on the lightning outages of these 132-kv. lines; but they definitely limit the damage to insulators and conductors, and reduce the amount of cascading required. Over the entire system (most of the system being equipped with grading shields) 23 per cent of the total number of tower flashovers occurred on cascaded strings. The lines on which grading shields were installed recorded only 21 per cent; lines with no shields, 70 per cent. This is a striking indication of the benefit rendered by grading shields.

4. Misleading conclusions may be drawn.

No interpretation of performance of lines under lightning conditions is possible or of real value without an accompanying record of lightning-storm conditions during the particular time discussed. Otherwise, conclusions gravely misleading may be reached.

5. Only one conductor usually involved.

Records of physical inspection and relay-target indications show that in from 4.7 to 5.8 per cent of trip-out cases due to lightning, all three phases are involved; in from 44.2 to 45.2 per cent, the top and middle conductors only are involved; in from 42.8 to 44.8 per cent the bottom and middle conductors are involved; and in from 78.2 to 64.2 per cent one phase only is involved. This analysis strongly indicates that both direct and induced strokes are of vital importance in the performance of this 132-kv. network.

6. Effect of tower footing resistance problematic.

Detailed data on the tower footing resistances on four 132-kv. lines show no tendency for lightning flashovers to concentrate on towers of high footing resistance in preference to those having low footing resistance. In fact, from these data, whether lightning strikes a tower with low or with high footing resistance seems to be a matter of chance. Flashed-over towers were observed to have footing resistances ranging from 1.5 to more than 250 ohms; and 65 per cent of all recorded flashovers occurred at towers having footing resistances of 20 ohms or less while less than 8 per cent occurred where this resistance was 80 ohms or more.

In general there is close agreement between these conclusions and those arrived at on the basis of the special field investigations. By way of comparison, however, it seems pertinent to mention the following points:

It is generally agreed that efficient ground-wire protection will reduce greatly the number of line outages due to lightning. Bell and Price have found in addition that a counterpoise greatly improves the efficiency of ground-wire protection and thus provides an additional factor of safety, especially where tower footing resistances are high. Fortescue and Conwell state that ground-wire protection near stations should be especially good in order that station equipment (which usually is not as highly insulated as the lines) be provided with the greatest possible amount of protection.

In regard to induced surges versus those caused by direct hits, Bell and Price believe that only in rare cases are induced voltages of sufficient magnitude to cause flashovers on 220-kv. lines. Pittman and Torok in speaking of wood pole lines also state that voltages dangerous to line insulation and equipment in most cases are set up only by direct hits.

There seems to be some disparity in regard to the effectiveness of low tower footing resistance. Fortescue and Conwell report no flashovers on lines equipped with ground wires where footing resistances were less than 5 ohms. Lewis and Foust support this view by calling attention to a 14-mi. 66-kv. double-circuit steel tower line of the Philadelphia Electric Company which has not suffered a lightning interruption for 14 years. This particular line has tower footing resistances of about 4 ohms each and is equipped with two overhead ground wires. Gross and Cox state definitely that an attempt to relate line flashovers to tower footing resistances proved futile while Bell and Price say that the effect of footing resistances higher than 17 ohms seems to be negligible.

Single Patent Appeal Court is Proposed

By
EDWIN J. PRINDLE Patent Attorney
Member A. I. E. E. New York, N. Y.

On the basis of long practical experience the author condemns the present procedure in patent litigation and outlines the foundation for a proposed single United States Court of Patent Appeals which would be second only to the U. S. Supreme Court and would abolish the duplicate and conflicting efforts of the ten district courts in patent matters. Full text of a proposed House of Representatives bill is given.

BECAUSE of the peculiar nature of the patent monopoly, the present system of appeals in patent infringement suits in the United States is the most inefficient, expensive and wasteful to be found anywhere. It is a deterent to the production of inventions, and to the investment of capital in patents. Correction of this condition is by far the greatest need of our patent system.

PRESENT SYSTEM—NATURE AND DEFECTS

For the first century of our patent system, there was a single court of patent appeals, the Supreme Court of the United States. This court became so overburdened with work that, in 1891, the appeal to the supreme court was taken away; and the country was divided into nine circuits (now ten), each of which was provided with a circuit court of appeals, having final and supreme jurisdiction of all patent appeals in its circuit.

These courts are independent of each other. While, under the doctrine of comity and unless they see substantial reasons for not doing so, they follow a previous decision by the court of appeals of another circuit on the same patent, they are at liberty to decide oppositely and frequently do so.

As stated, there is no appeal to the supreme court except that of petitioning that court to grant a writ of certiorari ordering the case to be sent up to it. The supreme court has such an enormous volume of work that it does not take up a patent case unless there is some question of public importance, of interpretation of law, or unless two circuit courts have decided the same question concerning the same patent in opposite ways. The decision of a single circuit court of appeals is final in most branches of the law (practi-

---

Essentially complete text from a pamphlet released May 25, 1931, by Edwin J. Prindle, chairman of the American Engineering Council's patent committee, 111 Broadway, New York, N. Y.

cally the only other exceptions being copyright and trade-mark matters). This is not so as to patents.

The monopoly which a patent grants is a negative one. The patentee is not granted the right, himself, to make, use or sell the patented invention—a *positive* monopoly. He already has that right because of his inventorship, unless in doing so he would have to use that which has already been patented to another. The patent merely grants him the *negative* right to exclude all others throughout the United States, from making, using and selling the patented invention. To be of any value to him, his monopoly must be maintained inviolate. If there is one infringer anywhere in the United States who has been rendered immune from the patent by a final decision, it will greatly impair and may largely destroy the value of the patent. One hole that cannot be stopped may sink a ship.

Under these circumstances, to make it necessary that the patent shall have been adjudicated oppositely in two separate circuit courts of appeal before the mere right shall exist to petition the one court which can render a final decision, the supreme court, to take it up is a shocking economic waste. A patent may be valid in one circuit and invalid in another. It may have been given a broad, inclusive, interpretation in one circuit, and a narrow one in another. It may be infringed by a given construction in one circuit, and not infringed by the same construction in another. A defendant in whose favor a patent in one circuit has been held invalid, or not infringed, is free to make, use, and sell in every other circuit; the patentee cannot even enjoin his agents or customers. Thus, in a single circuit, a patent may be invalid as to one person or corporation and valid as to everyone else, or *vice versa*. Even if a patent has been sustained in two circuits, there still are eight circuits, any one of which could decide to the contrary.

If the first of two decisions by a different circuit court of appeals is against a patent, and the supreme court decides in favor of the patent, it almost invariably is too late for the decision of the supreme court to affect the first case; and the defendant in that case is free to infringe the patent throughout the remainder of its life and throughout the whole country. Furthermore, the statute provides that where the patent covers more than the patentee invented he must, with reasonable promptness, file a disclaimer in the U. S. Patent Office disclaiming that which is not his invention. Where in the first suit under the patent a court of appeals holds a claim to be invalid, it must promptly be disclaimed under penalty of the patentee losing the right to bring other suits under the patent. The law provides that the disclaimer becomes a part of the patent, and is effective throughout the United States in all circuits. Thus patents may be nullified irretrievably because of a plurality of courts of appeals. With a single Court of Patent Appeals, the validity of the claims could be finally determined before any disclaimer was filed. Moreover, by the time the patentee has obtained a favorable decision in a second circuit in any of these cases, much of the short life of the patent (seventeen years) usually has expired with no substantial reward to the inventor. Expenses of these repeated litigations make them impossible to the individual, and constitute a burden from which even large corporations shrink.

With ten courts of appeals there are unavoidable differences of opinion on various points of law and differences of tradition as to the liberality or strictness of construction to be applied to a patent under the same circumstances. Under a single court of patent appeals the administration of the patent law would attain completeness and certainty and uniformity of application now lacking in these and other respects. Patents also involve many difficult questions of science and engineering, upon which judges may and often do differ. Thus it is impossible for the decisions of various circuit courts of appeals on the same patent always to be uniform.

Quite as many adjudicated patents are held to be invalid as are sustained. Both the public and the patentee, therefore, need to know early in the life of the patent whether or not the patent is valid, and what is its scope. If the patent is invalid the public should know it through a single final decision, and not be kept in uncertainty for years during which it would have been free to use the alleged invention described in the patent. However, if a patent is valid, the patentee early in the life of his patent should have a single decision which applies throughout the United States and which would hold against all subsequent defendants, unless they set up defenses substantially different from those considered in the first suit, or unless they use a structure outside the monopoly of the patent as determined in the first suit.

The patent should be adjudged as to validity, scope and infringement, on the same principles and policy throughout the United States, both for the sake of the public and the patentee. The head of the patent department of one of the largest corporations in this country said to the writer recently, "Whether a patent is valid or invalid, we want, early in its life, to know definitely so that we may shape our course accordingly and with confidence that the situation will not be changed during the life of the patent, except for substantial reasons."

The only solution of the difficulty is a "single court of patent appeals."

HISTORY OF LEGISLATIVE EFFORTS

In 1903 the American Bar Association approved the principle of a report of its patent committee recommending the establishment of a single court of patent appeals, and directed that committee to lay a bill for that purpose before Congress. The particular bill then proposed was not approved, but the principle of a single court of patent appeals was approved, leaving the form of the bill open. Mr. Frederick P. Fish was chairman of the patent section, and vigorously advocated the bill, which provided for a chief justice, appointed for life, and six judges chosen from the circuit and district courts to sit for terms of six years each.

Both the 1903 attempt and a subsequent attempt made in 1919 failed, however. The House Committee refused to approve the bill because it became apparent that judges would not break up their homes and interrupt their friendships and their children's schooling and go to Washington merely for a term of six or possibly twelve years. It became clear that appointments would have to be permanent to induce judges to become members of the proposed court.

Meanwhile, the need for a single court of patent appeals has been growing constantly. Such a court is now a practical necessity. It would substantially stimulate inventing and would protect both the patentee and the public from enormous unnecessary expense.

The American Engineering Council recently has approved renewing the legislative effort with a bill curing the former objections. The National Association of Manufacturers again has passed a resolution approving of the principle of a single court of patent appeals, and the undertaking of another campaign at this time to enact a bill for the purpose. Also, various committees of patent law associations are considering the advisability of a renewed effort to secure a single court of patent appeals.

PROVISIONS OF PROPOSED BILL

The writer has prepared a bill which provides for a single court of patent appeals sitting at Washington, and composed of a chief justice and six associate judges, five of the seven judges to constitute a quorum. Not only the chief justice, but the associate judges are to be appointed, as the Constitution says, "during good behavior." The proposed court is to have final jurisdiction of all appeals in patent cases from the District Courts of the United States and from the Supreme Court of the District of Columbia, both in interlocutory and final orders and decrees, jurisdiction of the United States Circuit Courts of Appeals in patent appeals being abolished. The power of the Supreme Court of the United States to order cases certified to it, is extended to include the proposed single court of patent appeals, and the right is given to that court to certify questions to the Supreme Court for instructions.

Salaries of the chief justice and the associate judges of the single court of patent appeals as proposed are $13,500 for the chief justice, and $13,000 for the associate judges. These are higher than those of the circuit courts of appeals, thereby ranking the single court of patent appeals next to the Supreme Court of the United States. This undoubtedly would assure that a sufficient number of the best qualified judges in patent cases will be available for appointment to the proposed court.

That the judges shall be specially qualified for the adjudication of patent cases in the single court of patent appeals, the bill provides that "experience in the adjudication of a substantial number of patent cases on the federal bench, or in the practise of patent law in the federal courts, shall be requisite to appointment as chief justice or a judge of said court, to the end that only judges who have shown special aptitude for the adjudication or the practise of the patent law shall be appointed to said court." Further experience and observation show that, by the adjudication of many patent cases, they would acquire a facility for comprehending the science and engineering of patent cases which would enable them, to a much greater extent, to make a selection on their own judgment between the conflicting opinions of experts.

The proposed bill changes the name of the court of customs and patent appeals to the "court of customs and patent office appeals," and it does not provide for appeals therefrom to the single court of patent appeals. However, an applicant for a patent (in every case except where the commissioner of patents is a necessary party, instead of appealing from the commissioner of patents to the court of customs and patent appeals) could reach the proposed single court of patent appeals by appeal on a bill in equity filed in the Supreme Court of the District of Columbia or, where the opposing party in the interference is not a resident of the District of Columbia, by an appeal on a bill filed in the district court of the district of which his opponent is a resident.

The establishment of a United States Court of Patent Appeals not only would be a great benefit to patentees and to the public, but will increase the effectiveness of patents, and prolong the productive portion of their terms. It would also substantially stimulate inventiveness and the building of businesses under patents. Establishment of the U. S. Court of Customs Appeals (now the U. S. Court of Customs and Patent [Office] Appeals) affords a precedent for the establishment of a single U. S. Court of Patent Appeals.

It is believed to be entirely possible to secure the establishment of a single court of patent appeals at this time if sufficient support is given by those who realize the importance of the patent system to the United States.

Attention is invited to the following draft of the proposed bill for a single court of patent appeals, the principal provisions of which have just been outlined.

COMPLETE TEXT OF PROPOSED H. R. BILL

IN THE HOUSE OF REPRESENTATIVES

A BILL

To Establish a Single United States Court of Patent Appeals, To Change the Name of the United States Court of Customs and Patent Appeals, and for Other Purposes

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that there is hereby created an United States Court of Patent Appeals, which shall consist of seven justices, of whom five shall constitute a quorum, and shall be a court of record with jurisdiction as is hereinafter limited and established. Such court shall prescribe the form and style of its seal and the forms of its writs and other process and procedure as may be conformable to the exercise of its jurisdiction as shall be conferred by law. It shall have the appointment of the marshal of the court, who shall have the same powers and perform the same duties under the regulations of the court as are now provided for the marshal of the Supreme Court of the United States, so far as the same may be applicable. The Court shall also appoint a clerk, who shall have the same powers and perform the same duties now possessed and performed by the clerk of the Supreme Court of the United States, so far as the same may be applicable. The salary of the marshal of the court shall be $3,500. a year, and the salary of the clerk shall be $5,000. a year, both to be paid monthly in twelve equal payments. The costs and fees now provided by law in the Supreme Court of the United States shall be the costs and fees in the United States Court of Patent Appeals; and the same shall be collected, expended, accounted for, and paid over to the Treasury Department of the United States in the same manner as is provided by law in respect to the costs and fees in the Supreme Court of the United States. The Court shall have power to establish all needful rules and regulations for the conduct of its business within its jurisdiction as conferred by law.

Sec. 2. That the President of the United States, by and with the advice and consent of the Senate, shall appoint a chief justice, and six associate justices of said United States Court of Patent Appeals, and as vacancies occur shall in like manner appoint others to fill such vacancies from time to time. The acceptance of one of said offices by a circuit or district judge of the United States shall vacate his office as circuit or district judge. Experience in the adjudication of a substantial number of patent cases on the Federal bench or in the practice of the patent law in the Federal courts shall be requisite to appointment as chief justice or an associate justice of said court, to the end that only judges who have shown special aptitude for the adjudication or the practice of the patent law shall be appointed to said court. Appointment to said court shall be during good behavior.

Sec. 3. That a term of the United States Court of Patent Appeals shall be held annually at the City of Washington, beginning on the second Tuesday of October in each year, and the same may be adjourned from time to time as the court shall order. If at any time for the meeting of the court a quorum of the justices shall not be present, the justices present may adjourn the court and, if necessary, adjourn again from time to time until a quorum appear. If at any sitting of the Court, the Chief Justice shall be absent, the associate justice senior in commission as a circuit judge, or senior in age in case of commissions of even date, shall preside. If no associate justice who has been a circuit judge shall be present, the associate justice senior in commission as a district judge shall preside. In case of commissions of even date, the justice who is senior in age shall preside. Upon a request of the Chief Justice, or a presiding associate justice of The Court of Patent Appeals, the Chief Justice of the United States shall designate a judge, or judges, of any federal court to fill a temporary vacancy in the said Court of Patent Appeals. Until it shall otherwise be provided by Congress, the sessions of the court shall be held in a building or rooms to be provided by the marshal of the District of Columbia, under the direction and approval of the Attorney General of the United States. The court shall by order authorize its marshal to employ such deputies and assistants for himself and the clerk of the court and such criers, bailiffs, and messengers as the business of the Court shall require, and to pay the salaries of such employees at rates of compensation not exceeding those paid for similar services in the Supreme Court of the United States, and to pay all other necessary incidental expenses of the court. The Chief Justice and each of the Associate Justices shall be entitled to employ a clerk, whose salary, at a rate not exceeding that allowed the clerks of the Chief Justice and associate justices of the Supreme Court, shall be paid as part of the expenses of the Court. The Court shall have power, in its discretion, to appoint a reporter and to fix by order his salary or other compensation and direct the form and manner of the official publication of its decisions.

Sec. 4. That the Chief Justice of the United States Court of Patent Appeals shall receive a salary of $13,500. per year. The Associate Justices of the said court shall each receive a salary of $13,000. per annum. All the said salaries shall be payable in twelve equal monthly installments. The time during which any Justice shall serve in said court shall be deemed continuous service with that in any other court of the United States, before or after such service within the meaning and intent of Section Three Hundred and Seventy-five of title Twenty-eight of the United States Code.

Sec. 5. That the United States Court of Patent Appeals shall have jurisdiction to hear and determine appeals from final judgments and decrees in the district courts of the United States and in the Supreme Court of the District of Columbia in cases arising under the laws of the United States relating to patents for inventions, and from final judgments and decrees in cases arising under the laws of the United States relating to patents for inventions rendered by any other court having jurisdiction under the laws of the United States to hear and decide such cases in the first instance: Provided, however, that it shall have no jurisdiction of cases originating in the Court of Claims nor of cases in which the Commissioner of Patents is a necessary party. All such appeals shall be taken within three months after the entry of the order, judgment, or decree sought to be reviewed. The practice, procedure, and forms to be observed in the taking, hearing and determination of such appeals shall conform to the practice, procedure, and forms observed in like cases in the Supreme Court of the United States, subject to such rules and regulations as shall be prescribed by the Court. The said Court shall have power to prescribe the forms of records on appeals thereto.

Sec. 6. That whenever, by an interlocutory order or decree in a district court of the United States, in the Supreme Court of the District of Columbia or other Court having jurisdiction under the laws of the United States to hear and decide in the first instance cases arising under the patent laws, in a case in which an appeal may be taken from the final decree of such court to the United States Court of Patent Appeals, an injunction or restraining order shall be granted, or refused, or continued, or vacated, or modified, or retained without modification after motion to modify the same, an appeal may be taken from such order or decree by the party aggrieved to the United States Court of Patent Appeals: Provided, That the appeal must be taken within thirty days from the service of notice of entry of such order or decree; and it shall take precedence in the appellate Court; and the proceedings in other respects in the court below shall not be stayed unless otherwise ordered by that court, or the United States Court of Patent Appeals, or a judge thereof, during the pendency of such appeal.

Sec. 7. That the chief justice and the associate justices of the United States Court of Patent Appeals shall each exercise the same powers in term and vacation in the allowance of appeals, supersedeas orders, and other matters incidental to the jurisdiction and business of the Court as are now exercised by the Chief Justice and associate justices of the Supreme Court of the United States in relation to the business and jurisdiction of that Court.

Sec. 8. That the decisions of the United States Court of Patent Appeals in all cases within its appellate jurisdiction shall be final, except that it shall be competent, as hereinafter provided for the Supreme Court of the United States to require, by certiorari, or otherwise, any such case to be certified to it for its review and determination with the same power and authority in the case as though it had been carried by appeal from the trial court directly to the Supreme Court.

Sec. 9. That whenever any case shall have been certified from the United States Court of Patent Appeals to the Supreme Court of the United States, by certiorari or otherwise, it shall, upon its determination by the Supreme Court, be remanded to the district court of the United States or other court in which it originated for further proceedings to be taken in pursuance of such determination. And in every case determined by the United States Court of Patent Appeals upon appeal, the case shall be remanded to the District Court of the United States or other Court from whence it came, for further proceedings to be taken in pursuance of such determination.

Sec. 10. That all appeals in cases in which appellate jurisdiction is by this Act conferred upon the United States Court of Patent Appeals which shall have been pending without hearing in the United States Circuit Courts of Appeals or other court of appellate jurisdiction for less than three calendar months prior to the taking effect of this Act shall be transferred from such circuit courts of appeals or other courts to the United States Court of Patent Appeals and be heard and determined in that court as though they had been taken there from the trial courts by appeal without further payment for certifying the record or any new or additional docket or calendar fee; all other appeals and writs of error in cases in which appellate jurisdiction is by this Act conferred upon the United States Court of Patent Appeals which shall be pending in the United States circuit courts of appeals or other courts of appellate jurisdiction at the time of the taking effect of this Act shall remain and be heard and determined by the courts in which they may be pending, respectively, as though this Act had not been passed.

Sec. 11. That after the taking effect of this Act no appeal shall be taken from any district court or from the Supreme Court of the District of Columbia or other Court of the United States to any United States circuit court of appeals or other appellate court in any case in which an appeal may be taken to The United States Court of Patent Appeals under the provisions of this Act. If, in any case, it is found that no substantial question under the patent laws is raised by the appeal, the court may order that such appeal be sent to the circuit court of appeals having jurisdiction over the district in which the suit was brought, or the Court of Appeals of the District of Columbia, as the case may be; if any appeal shall be taken to any circuit court of appeals, or to the Court of Appeals of the District of Columbia, and such court shall find that such appeal involves a question arising under the patent laws of the United States, except in a case where the Commissioner of Patents is a necessary party, such court shall order such appeal to be sent to the Court of Patent Appeals, and no appeal shall be dismissed solely on the ground that the appeal has been taken to the wrong court.

Sec. 12. Section 301a of Title 28 of the United States Code is hereby amended to read as follows:

> The title of the United States Court of Customs and Patent Appeals, created by Section 301 of this title, is hereby changed to The United States Court of Customs and Patent Office Appeals.

Sec. 13. Section 346 of Title 28 of the United States Code is hereby amended to read as follows:

> In any case, civil, or criminal, in The United States Court of Patent Appeals, in a Circuit Court of Appeals, or in the Court of Appeals of the District of Columbia, the Court may at any time certify to the Supreme Court of the United States any questions or propositions of law concerning which instructions are desired for the proper decision of the cause; and thereupon the Supreme Court may either give binding instructions on the questions and propositions certified or may require that the entire record in the cause be sent up for its consideration and thereupon shall decide the whole matter in controversy in the same manner as if it had been brought there by writ of error or appeal.

Sec. 14. Paragraph (a) of Section 347, Title 28 of the United States Code is hereby amended to read as follows:

> (a) In any case, civil or criminal, in a circuit court of appeals, or in the United States Court of Patent Appeals, or in the Court of Appeals of the District of Columbia, it shall be competent for the Supreme Court of the United States, upon the petition of any party thereto, whether Government or other litigant, to require by certiorari, either before or after a judgment or decree by such lower court, that the cause be certified to the Supreme Court for determination by it with the same power and authority, and with like effect, as if the cause had been brought there by unrestricted writ of error or appeal.

Sec. 15. That Sec. 377, Title 28 of the United States Code, be amended to read as follows:

> "Power to issue writs. The Supreme Court, and the District Courts shall have power to issue writs of *scire facias*. The Supreme Court, the Court of Patent Appeals, the Circuit Courts of Appeals, and the District Courts shall have power to issue all writs not specifically provided for by statute, which may be necessary for the exercise of their respective jurisdictions and agreeable to the usages and principles of law."

Sec. 16. That all laws and parts of laws inconsistent with the provisions of this Act are hereby repealed.

Sec. 17. That this Act shall take effect and be in force on the day of nineteen hundred and

Twin Motors for Heavy Rolling Mills

By
R. H. WRIGHT Member A. I. E. E. Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
H. E. STOKES Non-member Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Twin-motor drive has met effectually the repeated demands for more power at the rolls. Other advantages, however, which now far overshadow the improvement originally sought are the direct outcome of the reduced inertia and greater operating flexibility inherent in this type of drive.

TWIN-MOTOR DRIVE for heavy blooming and slabbing mills has grown out of an increasing demand for power at the rolls greater than can be provided conveniently by conventional design methods. At the same time, this new development is a logical step in the modern trend toward greater mechanical simplicity in rolling-mill machinery. Already two machines, one a 54-in. blooming mill, the other a 44-in. slabbing mill, each with main rolls driven by independent motors, are in successful operation.

The principal advantages which these installations have exhibited can be summarized as follows:

1. Greatly increased motor capacity may be applied to a single pair of rolls.
2. Pinion losses with their attendant repair and maintenance are eliminated.
3. Twin motors may be designed to have greatly reduced inertia. This means less strain on equipment, more torque available for useful work, reduced motor and generator heating, and greater acceleration.
4. Roll chatter and spindle vibration are practically eliminated.
5. Higher rolling speeds can be maintained and mill tonnage can be increased.

The term "twin-motor" has come to refer to a form of rolling-mill drive in which each of a pair of rolls is independently driven by a separate motor. In a true twin-motor drive the motors may not operate at exactly the same speed at all times; nor do they depend entirely upon the coupling effect of the metal being rolled to maintain correct load division and speed relations.

Independent drive for the working rolls has been used previously in wheel and tire mills, piercing mills, and tube expanders and reelers. In these installations the motors rotated in one direction only at practically constant speed, the metal between the rolls providing an

---

effective coupling and rather definitely fixing the speed and load relations. Reversing-beam mills with independently driven edging rolls also were in successful operation. Here experience demonstrated that the speed relations of two reversing motors working on the same piece of steel could be adjusted to take care of varying drafts with no indication of unusual roll slippage.

When the electrical equipment for the 54-in. blooming mill first was considered it was felt that, to provide power for rolling heavier sections at higher tonnage rates, the continuous capacity and maximum torque of the reversing motor should be greater than had been used previously.

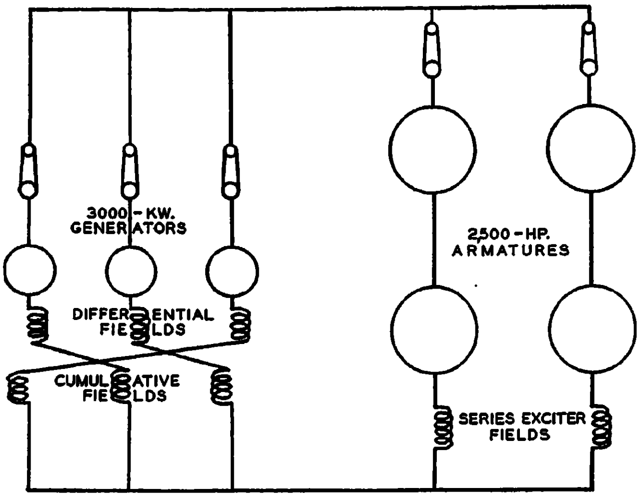

Fig. 1. Main connection diagram for 10,000-hp. twin-motor drive and associated generators

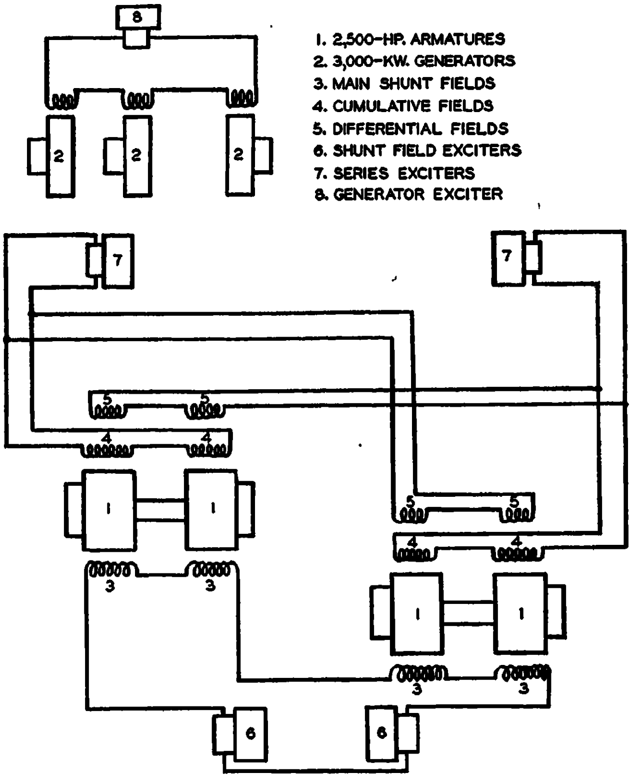

Fig. 2. Field-circuit connections for 10,000-hp. twin-motor drive

Accordingly both 10,000- and 12,000-hp. equipments with maximum torques of 3,940,000 and 4,725,000 lb-ft. respectively were considered, since a duplicate mill already had been built with an 8,000-hp., 50-r. p. m. drive having a rated maximum torque of 2,500,000 lb-ft. It was thought then that for the higher motor torques the drive for the new mill could be improved mechanically by eliminating the mill pinions. This mechanical improvement now has been realized but other advantages as outlined in the beginning so far outweigh those expected that what previously were considered foremost, now seem insignificant. This, of course, is the usual story of many new developments.

Design Difficulties Involved

Design of reversing equipments for machines of this size presents some interesting problems. A motor with a single-unit armature would have the advantages of simplicity and comparatively high efficiency. However, the maximum capacity which so far has been built into a single-unit armature is 8,000 hp. at 40 r. p. m., and a motor of this size has an armature which approaches the largest that can be shipped in one piece. Using present design proportions, about 10,000 hp. continuous capacity at 40 r. p. m. with 3,300,000 lb-ft. maximum torque would be the largest motor which could be built with a single-unit armature. The inertia of such a motor, however, would be tremendously high—in fact about 2.3 times that of the 10,000 hp. twin-motor drive finally adopted.

A double-armature motor offers the next best possibility for a single machine of 10,000- or 12,000-hp. capacity at a speed of the order of 40 r. p. m., but even in this type of machine, the inertia would be nearly twice that of an equivalent twin-motor drive. Construction of the electrical equipment for high-capacity reversing drives thus obviously is somewhat more complex than for small and medium ratings.

In addition to the disadvantages of large single-motor drives already mentioned, pinion stands suitable for transmitting torques of from 4,000,000 to 5,000,000 lb-ft. become extremely large and heavy and their design and manufacture involve serious mechanical problems. For large mills, therefore, the twin-motor drive offers both mechanical and electrical advantages.

The twin-motor drive finally selected for the 54-in. blooming mill consists of two 5,000-hp., 40/80-r. p. m. double-armature motors with a combined maximum torque rating of 3,940,000 lb-ft. Each armature is wound for 350 volts, the two armatures of one motor being connected in series, as shown in Fig. 1. The two motors operate in parallel and receive power from three

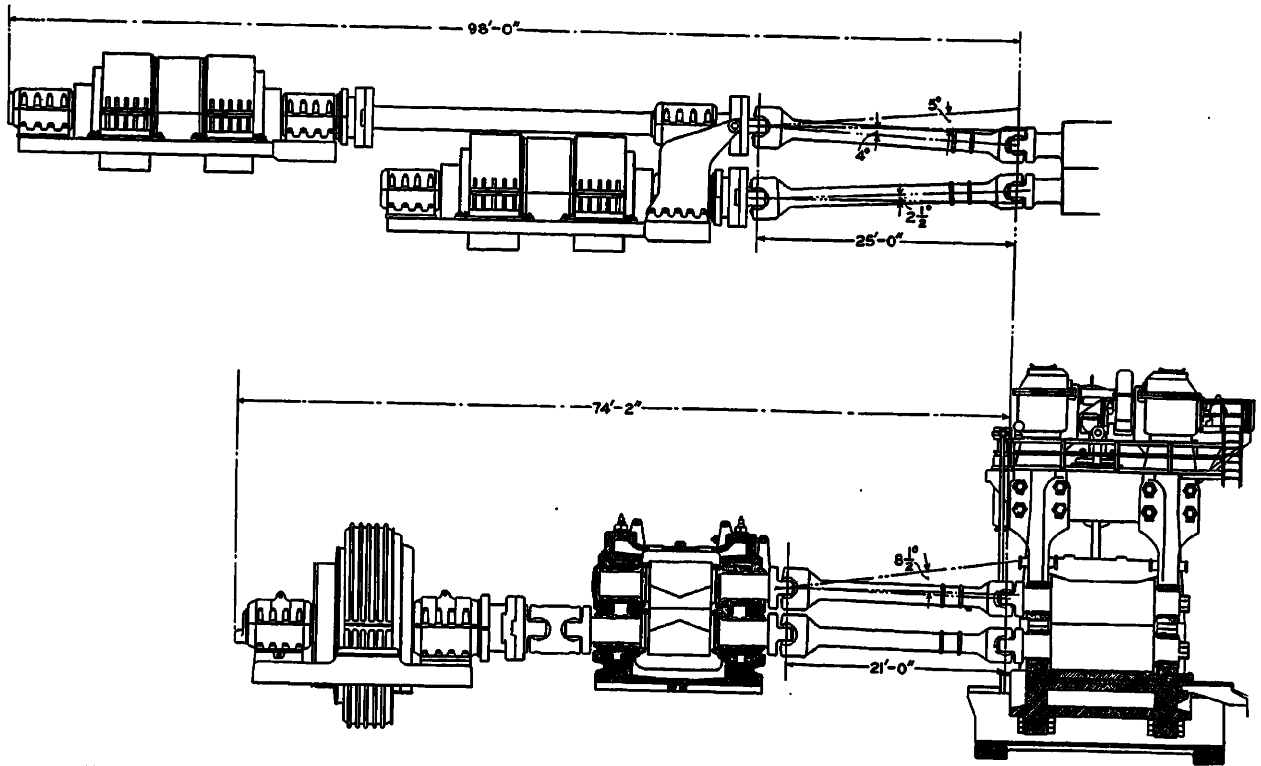

Fig. 3 General layout of 10,000-hp. twin-motor drive (above) and 8,000-hp. single-motor pinion drive (below) for 54-in. blooming mill. Note comparative space requirements

3,000-kw., 700-volt generators, also connected in parallel. The motor-generator is equipped with a 90-ton, 15-ft. diameter steel-plate flywheel, and is driven by a 6,500-hp., 368-r. p. m. induction motor.

Electrical Features

A diagram of the field circuit showing the method of field control may be seen in Fig. 2. All shunt fields of both double-armature motors are connected in series, thus insuring the same shunt-field excitation for both motors. As may be noted, two shunt-field exciters are employed for the motors in order to permit the use of standard 250-volt exciter generators. This arrangement also makes possible the variation of the relative shunt excitation of the two mill motors, if necessary, by means of a buck-and-boost exciter connected across the mid-point of the field circuit and a point midway between the two exciters. Up to the present time, however, no occasion has been found to make use of this latter feature.

In addition to the main shunt-field winding each motor is equipped with a cumulative series field and a differential series field which are cross-connected and indirectly excited by series exciter generators. As shown in Fig. 2 each series exciter generator has its series field in the armature circuit of one double-armature motor, and excites the cumulative field of that motor and the differential field of the other motor. Hence any tendency of one motor to take more than its share of the load strengthens its field and weakens the field of the other motor, thus quickly reestablishing equilibrium.

With this load-balancing scheme, any desired speed regulation can be obtained without interfering with the load-balancing characteristics—a valuable feature indeed. Of note also is that the load-balancing effect can be varied without affecting the compounding.

A similar scheme is used to balance the loads on the three generators of the motor-generator set except that the generator series fields are excited directly without the use of series exciters, and that each generator excites its own differential field and the cumulative field of the adjacent generator.

Mechanical Features

Mechanical arrangement of motor, spindles, and rolls is shown in Fig. 3. The motors are mounted on on 83.5-in. centers. Relative elevations of motors and rolls are such that the lower spindle operates at an angle of 2.5 deg.; the upper spindle runs at an angle of 4 deg. below horizontal when the rolls are together and 5 deg. above horizontal when the rolls are set for their maximum separation. The mill spindles are 25 ft. long, which is 4 ft. greater than for a duplicate mill with pinions. The maximum angle of the upper spindle for the pinion drive, corresponding to the same roll separation, is 8.5 deg.

Comparative space requirements and spindle angles for an 8,000-hp., 40-r. p. m. drive with pinions, and for a 10,000-hp., 40-r. p. m. twin-motor drive are shown also in Fig. 3. As may be noted with the pinion drive, the spindles operate under the most favorable conditions when the rolls are close together. Usually, however, loads are heaviest when the ingot being rolled is large and the upper spindle considerably inclined. With twin-motor drive the spindle angle is at minimum when the rolls are separated considerably; hence with this type of drive the best operating conditions obtain when the load is at maximum.

Mechanically, the two motors of a twin drive are identical. The mill-end pedestal of each motor is supported on a heavily ribbed cast steel baseplate. The sides and front end of the bedplate are fabricated in the usual manner from heavy beams and slabs. The upper motor drives through a jack shaft, an "A" frame on the mill end of the lower motor supporting a pedestal bearing which carries the outer end of this shaft. Thrust in this jack shaft is taken care of by the mill-end pedestal of the upper motor. The lower motor is provided with the usual type of thrust bearing. Both the motor shafts and the jack shaft have forged flanges. Driving halves of the universal couplings next to the motors are bolted to the shafts in such a way that they can be removed for renewal or repair. Electrical construction of the motors is in accord with accepted practise for reversing service.

CHARACTERISTICS OF TWIN- VS. SINGLE-MOTOR DRIVES

Operating characteristics of the 10,000-hp. twin-motor drive are quite different from those of a conventional reversing equipment driving through pinions. These differences are indicated in the following comparisons.

1. Quieter operation.

Steel enters the rolls without shock. The usual vibration and noise in the mill spindles are absent, and there is practically no tendency for the mill to chatter. Consequently the roller is not required to exert the usual care but can enter the steel on the first trial, even at higher speed thereby saving time on the early breakdown passes.

2. Greater operating flexibility.

In the pinion drive, independent movement of the rolls is limited by the back-lash in the pinions and spindles; this limitation of movement constitutes the chief cause of roll chattering. With twin-motor drive the phase positions of the rolls can shift independently thereby quickly adjusting themselves to the steel and largely eliminating roll chatter.

3. Higher mill acceleration and retardation.

Comparatively low inertia in the motors allows the control to be designed for unusually fast field response without setting up high reverse power currents. Electrical equipment is therefore used to better advantage and the capacity for useful work is increased.

4. Intervals between passes reduced.

This is brought about by the rapid response of the motors which not only makes the handling of the drive much easier than the usual drive, but also permits the steel to be kept closer to the mill.

5. Total rolling time decreased.

The quick response of the motors increases the entering and average rolling speeds, thereby decreasing the rolling time by increasing the percentage of the time the metal is in the rolls.

Twin-motor drive also has been applied recently to the main horizontal rolls of a 44-in. slabbing mill. This mill is similar to that of the 54-in. blooming mill except that the total capacity of the drive is greater. The main horizontal rolls are driven by a 10,000-hp., 40/80-r. p. m., twin-motor drive similar to that just described. The vertical rolls are driven separately by a 2,500-hp. 79/225-r. p. m. 700-volt reversing motor. The flywheel motor-generator comprises three 3,500-kw. 700-volt generators but otherwise is the same as the blooming-mill set.

TWIN MOTORS FOR SMALLER MILLS

The two installations just described are the first applications of twin-motor drive to heavy-duty mills and in addition represent the greatest power which so far has been applied to a single pair of rolls. For mills with 40-in. or smaller rolls requiring motor capacity of 8,000 hp. or less, the drive usually can be simplified by building each motor with a single armature. The smaller motors can be mounted on smaller centers and the spindle angles can be kept within reasonable limits without making the spindles excessively long.

It is possible from both the mechanical and electrical

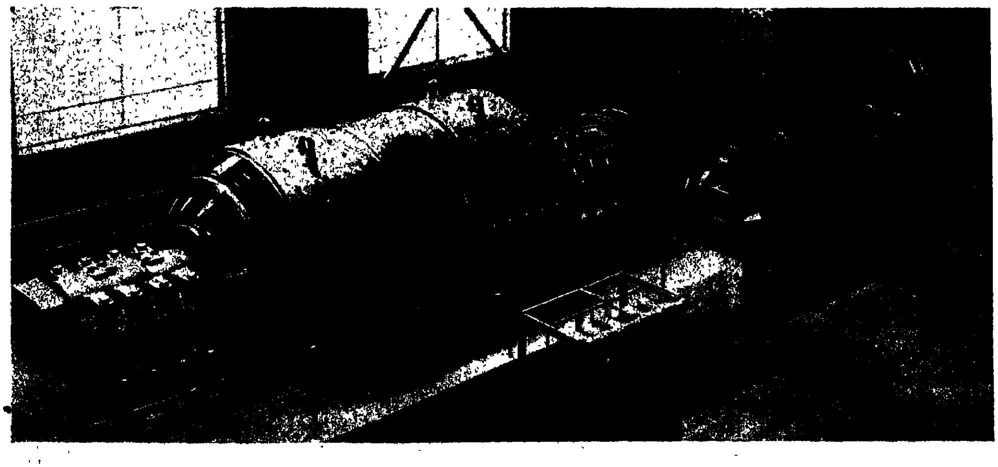

Fig. 4. General arrangement of the two 5,000-hp. double-armature motors as actually installed

standpoints to build a reversing mill drive with one motor on each side of the mill. With this arrangement small motor diameter is not an important consideration and the motors can be designed along conventional lines; where both motors are located on the same side of the mill, however, motor design may be somewhat special. However, within reasonable limits, electrical construction details are relatively flexible and each individual installation therefore should be laid out to fit local conditions most advantageously.

Cost and Other Considerations

Relative first costs of twin-motor reversing drive and pinion drive will vary with the size and torque requirements of the mill. The motors of a twin-motor drive with the necessary shafting and bearings are more expensive to build than a single motor of equivalent capacity. This increased cost may be somewhat less than the cost of a pinion stand with spare pinions and bearings for a heavy mill, but somewhat greater than these costs for a light mill. In general, however, the difference in cost is not great and is far outweighed by the many advantages of twin-motor drive.

Twin-motor drive offers advantages also for wide strip mills, whether these are used for hot or cold rolling. The chief advantage in this application is that the elimination of the mill pinions does away with the necessity for accurate matching of the mill rolls. When single-motor drive is used for either hot or cold rolling, unless the rolls are matched accurately, high stresses are set up in the pinions in order that the larger roll will slip and equalize the delivery speeds. With twin-motor drive the motor speeds readily adjust themselves so that each roll has the same surface speed. The problem of load division is quite simple, since wide thin material forms practically a perfect coupling between rolls.

The simplest form of drive for a strip mill is one having a direct-connected motor on either side of the mill, each motor driving one working roll. To this arrangement there may be objections, especially in hot-rolling mills, on account of the space occupied by the motor and spindles on the side of the mill usually left open. This objection can be overcome by the use of special gearing which will permit the installation of both motors on the same side of the mill. And since geared motors with pinion drive are now the usual thing, such an arrangement would introduce no new mechanical complications. The total number of gear units would remain the same, and instead of one reduction unit and one mill pinion unit, each of full capacity, there would be two reduction units, each of half the total capacity.

In recent years the conceptions of steel plant executives and engineers as to the expected output of various sizes and types of mills have become fairly well standardized. Certain standards also have been applied in selecting the electric drives. Where twin-motor drive is to be used, a revision of standards obviously will be necessary. Higher average rolling speed and the reduction of intervals between passes allow the capacity of such a mill to be increased over what would be expected from one with the conventional single-motor drive. The net result is a more advantageous utilization of electrical equipment in the twin-motor drive; hence a greater tonnage output can be realized with no increase in motor capacity. Moreover, in many cases it will be desirable to provide still greater motor capacity than now is customary in order to take advantage of every possibility for increased output.

A Vacuum-Tube Device for Current-Balance Telemeters

The motor-operated rheostat with its associated apparatus now is replaced by a simpler, more compact vacuum-tube arrangement. The only auxiliary power required can be obtained from an ordinary station-lighting circuit; circuit constants are chosen so that momentary dips in this supply voltage do not affect the readings.

PAUL MacGAHAN Westinghouse Elec. & Mfg. Co., Newark, N. J.
Member A. I. E. E.

AN IMPROVEMENT for current-balance telemetering systems recently has been devised, not only to eliminate the auxiliary motor and special rheostat now commonly used with this apparatus but also to render unnecessary an additional source of d-c. supply. This new improvement utilizes electron tubes for producing and controlling the feeble direct current which constitutes the indicating medium for this type of remote metering.

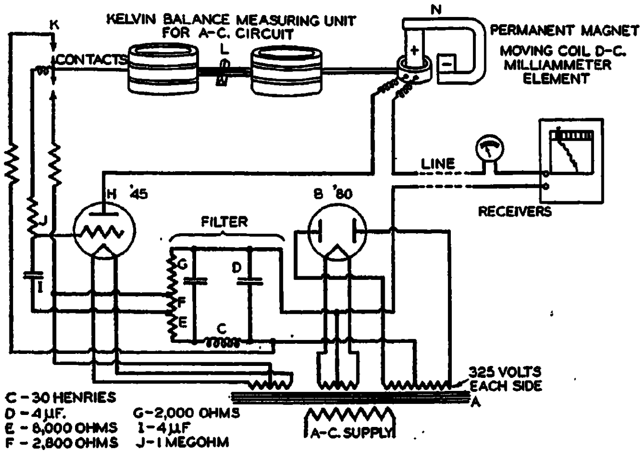
In general, telemetering systems are capable of a wide variety of applications including not only measurements of electrical quantities but also of many mechani-

---

Written specially for Electrical Engineering; not published in pamphlet form.

cal entities; for example, water-level indications in unattended hydroelectric stations. In the *current* type of apparatus as contrasted with other types the variations to be remotely observed are first translated into proportional currents; these are then transmitted over communication lines and measured at the remote receiving point by the usual type of current measuring instruments.

The current-balance system constitutes one particular species of current telemeter, utilizing a mechanism in which a direct current of *milliampere* magnitude is regulated to be proportional to the quantity being measured; this small direct current then being transmitted to the remote receiving point. As previously constructed the transmitter in this system consisted essentially of a composite a-c.—d-c. balance mechanism in which the torque of a-c. measuring coils was balanced against the counter-torque of d-c. coils. Current in the d-c. coils was adjusted by a motor operated rheostat, the motor in turn being actuated by contacts on the balance mechanism.



Schematic diagram of new vacuum-tube transmitter for current-balance telemetering

A schematic diagram of the new electron-tube current-balance transmitter may be seen in the accompanying illustration. Power, voltage, current, or whatever entity is to be remotely indicated is applied to the measuring element *L* and produces a torque tending to close one of the contacts *K*. An electromagnetic counter-torque is established by the d-c. element *N*, which carries the telemeter current in the communication line, this of course being the current measured by the remote receiving meters. These two torques are applied against each other by the composite a-c.—d-c. balance mechanism *L-N*. If they do not balance exactly, contacts *K* operate to adjust the direct current (which is supplied from the plate circuit of tube *H*) to the balancing value. When the upper contacts close, the grid voltage of tube *H* is increased and the plate circuit is correspondingly reduced; when the lower contacts close, the grid voltage is reduced thereby increasing the plate current. The resistance *J* slows down the charging time of the condenser *I* enough to allow the balance *L-N* to open the contacts and stop charging when the proper current value is reached.

Power is obtained for the electron tubes and associated equipment from an auxiliary a-c. supply such as a station lighting circuit. Transformer *A* supplies filament voltages to both tubes, and plate voltage to rectifier tube *B*. This latter tube supplies the d-c. plate and grid voltages for tube *H* through filter circuit *C-D* and resistor *E F G*.

Resistances *E*, *F*, and *G*, are so chosen that *G-F* will produce enough grid voltage to reduce the plate current to zero, when voltage equivalent to the drop on *G* is impressed on the plate. The resistance *F* is so chosen that when a sudden change occurs in the line voltage of the auxiliary supply *A*, no change in the plate current of tube *H* takes place. Thus this resistor arrangement prevents line supply dips from showing on the record, and thereby overcomes a condition existing in previous forms of current-balance systems.

Use of electron tubes in this apparatus eliminates all moving parts used previously, excepting of course those associated with the meter elements. Accordingly the up-keep expense and attention required should be less than with the older type of transmitting system. Life tests made in the laboratory indicate also that under normal operating conditions radio tubes as used in this application should have an average life of much more than a year. In addition to the distinct advantages already mentioned, the apparatus is more compact than the motor-operated device and the currents which contacts *K* are required to handle are greatly reduced being only from 40 to 80 microamperes.

Clinical Sunlight—

Natural and Artificial

DISCOVERY of reasons for the well-known beneficial effects of sunlight on health has been a stimulus to efforts to produce artificial sunshine for use when and where natural sunshine is not available. Knowledge of the amounts of energy in various wavelengths of the solar spectrum throughout

---

From an article written by A. O. Downes, National Carbon Co., for *Research Narratives*, Dec. 15, 1930, published by the Engineering Foundation, Inc., 29 West 39th Street, New York, N. Y.

the year is necessary for production of the best artificial sunlight. Therefore measurements of sunlight in summer, fall, and winter, have been made at two sanatoria, in Ohio and Colorado, where sunlight has been used for years in treating disease. The physicians in charge in Colorado have found that noon winter sunshine has given the best results.

There are indications that several more or less clearly defined bands of the spectrum produce certain biological effects. Most clearly defined is the so-called antirachitic region (limited to wave lengths less than 3,100 Angstrom units), which is included in that portion of sunlight entirely removed by ordinary window glass. (The Angstrom unit is equal to a ten-millionth of a millimeter.) This band is responsible also for sunburn. The band of very short ultra violet (not present in sunlight) below about 2,800 Angstrom units is destructive to bacteria and molds. There are other bands which have specific biological effects but the evidence is not so complete as yet as for the two bands mentioned.

Carbon arcs have been produced closely approximating the amount of sunlight in more or less narrow bands at definite distances from the source, and some of these carbon arcs have been in use for the treatment of disease ever since Finsen began using the carbon arc at Copenhagen about 1895. Finsen's work has been continued by physicians all over the world using various types of carbon arc as well as other sources of light.

The carbon arc has been a useful tool to these investigators as, by the use of various metals and chemical compounds in the carbons, the quality of the light produced can be varied through a wide range. If light rich in the far ultra-violet entirely absent in sunlight as it reaches the earth is desired, the carbons are cored with iron or a combination of several metals such as iron, nickel, and aluminum. Carbons containing silver have been used to produce a strong band in the ultraviolet just above the so-called antirachitic band (2,900 to 3,100 Angstrom units).

Ideal artificial sunshine should have only the wavelengths present in natural light and in exactly the same proportions. At present no artificial illuminant has been produced which exactly duplicates sunlight in the distribution of energy in the various wavelengths, but a light which closely approaches sunlight in quality is given by an arc burning carbons cored or impregnated with salts of the rare earths. There are several chemical elements in these rare earths, but their effect on the light from the carbon arc is due principally to the metal, cerium.

An important property of any carbon arc is that the light emitted is dependent only upon the grade of carbon—that is, the kind and quantity of chemical elements used in the cores—and the current and voltage at which the arc is burned. The quality of the light therefore is independent of the lamp mechanism, but the quantity and direction of the light depend very greatly upon the efficiency of the reflectors and other features of design.

Coordination—The Essence of Modern Engineering

By
WILLIAM S. LEE President A. I. E. E.

ENGINEERING ENTERPRISE has developed so rapidly from the application of individual technical skill to the combined technical efforts of many and variously qualified persons, that it seems propitious to consider briefly one of the most important of the present controlling features. A modern engineering undertaking of any appreciable size whatever involves influencing factors ranging all the way from the purely political to the purely economic; from the purely theoretical to the most simple and practical. Each of these factors of necessity must contribute its share to the ultimate design or structure, each to be interpreted and applied by a skilled technologist. Thus it is that coordination, hackneyed word though it be, comes to the fore as representing a function without which no engineering enterprise of any magnitude may hope to succeed in the full sense of that word.

Successful operation presupposes coordinated construction which in turn is dependent upon coordinated design, the whole enterprise resting fundamentally upon coordinated man power. The design of a modern complicated project represents the composite thought and combined experience of many minds so carefully blended, so well balanced, and so thoroughly interlocked, that each part will function and work in unison with every other part. Every project of any importance should be carefully designed in its entirety before very much if any of the construction work is undertaken. Only by this means may the construction engineer obtain the necessary insight into the ultimate purpose and use of the undertaking for which he is responsible, as well as the strength and character of each integral part, through which insight he may produce the desired results in the finished product. Only with a composite picture of the whole may the construction engineer proceed intelligently and meet modern economic limitations by building safely, quickly, and economically.

The achievement of a perfect structure in this day of broad and rigid requirements would be impossible without the assembled minds and the coordinated efforts of many kinds of engineers and technical specialists. In spite of this well-known fact, however, it is a common

---

An address delivered at the annual summer convention of the A. I. E. E., Asheville, N. C., June 22, 1931.

fallacy to look upon the result achieved as being the product of the efforts of one man. The really big man in engineering as well as in other professions is the simple man who readily recognizes and admits the fact that all major enterprises are fundamentally the products of well-directed group action. Very often the greatest and the most valuable man in a coordination conference is the man who can abandon his own ideas to espouse the cause of others in the interest of unified and effective effort.

In pausing for a moment to consider some practical examples we naturally turn to the field of electricity. One of the most perfectly coordinating forces in modern times is found in the transformation of energy into electric power and the application of this new form of energy into productive work. So perfect is the coordination that can be secured in the field of electricity that every phase of the almost innumerable detailed operations involved in a modern power plant may be so interlocked by electrical apparatus and so energized by electric power that they operate in perfect unison and always are ready with instantaneous response to the will of the operator in charge.

To cite another case of mechanical coordination, let us consider briefly the modern paper mill with which many of you are familiar. The real heart of this mill lies in the long line of rolls. These rolls are steam-heated and over them passes the paper as it evolves from a pulp to the finished product. Due to the fact that absolute uniformity of speed is required it was considered impossible until a few years ago to drive these rolls by any means other than spur gears. The electrical engineer, however, solved the situation by designing sensitive and accurate control equipment by means of which many electric motors may be electrically so interlocked as to maintain rigid synchronism. Thus these many independent motors turn the several rolls drawing the endless paper strips through them at a high speed, yet with a smoothness that avoids tearing even the most delicate paper.

As another example of coordinated effort consider the widely heralded Empire State Building in New York City. If prior to the completion of that structure you had visited the site and inspected the old building upon it, and had you been able to view the tremendous quantity of material of almost innumerable kinds that went into it, and then had been told just how long it would take to remove the old structures and assemble the raw materials into a new structure, you could have been pardoned for exhibiting grave doubt as to the possibility of accomplishing such a feat. Yet, as a result of strict coordination of design and construction, and the coordinated mobilization of the materials which had to be brought in piece by piece, that tremendous structure was completed within a phenomenally short time to its full height of 1,247 ft. above the sidewalk line.

The failure of the designing engineer or the construction engineer to coordinate their various related branches of engineering, construction, or specialization, can mean nothing but lost energy, lost time, and lost money in any great project.

In engineering, your mission, and mine, is far greater and more important then merely designing or constructing a great project. We must so synchronize the many kinds of engineering and the many kinds of materials involved that the finished product shall be perfect in its design, construction, and operation. In this connection it should be remembered specifically that the ultimate aim in every project is a perfect product rather than a perfect design. In the face of constantly increasing and ever more exacting demands in all kinds of engineering projects, we are training more engineers and more types of engineers year by year as specialists to refine and improve our general designs.

We must go further and maintain that initiative which builds the type of citizenship to which we owe our inventions, our developments, our progress—a citizenship far more valuable than the gold seams of arctic Alaska or the diamond fields of tropical South Africa—a citizenship that recognizes fully the fact that the only true equality in life is equality in opportunity.

In closing I wish to leave a message for the young engineer, and for the engineering student. It is my wish to impress these young men with the fact that opportunities still abound in the field of engineering in general, and electrical engineering in particular. True the specifications are somewhat broader and the requirements materially more rigid than they used to be; but to offset this, the young engineer of today has at his command a wealth of technological information nonexistent in earlier days. In my own opinion the wonderful field of coordination upon which I have touched but briefly now furnishes a new line of endeavor for you young engineers, and opens up a magnificent panorama of opportunity for service to yourselves and to your country.

If it were possible for Opportunity to stand before you today she doubtless would say:

"They do me wrong who say I come no more
When once I knock and fail to find you in;
For every day I stand outside your door,
And bid you wake, and rise to fight and win.

Wail not for precious chances passed away,
Weep not for golden ages on the wane;
Each night I burn the records of the day;
At sunrise every soul is born again.

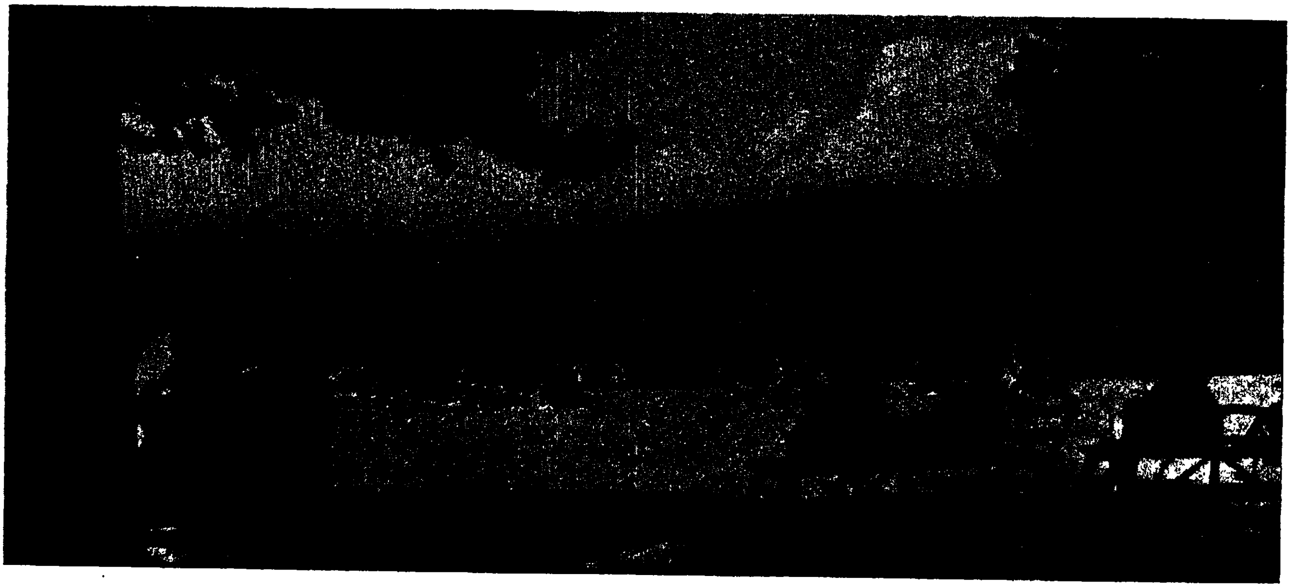
Laugh like a boy at splendors that have sped:
To vanished joys be blind and deaf and dumb;
My judgments seal the dead past with its dead,
But never bind a moment yet to come.

Though deep in mire wring not your hands and weep;
I lend my arm to all who say 'I can!'
No shamefaced outcast ever sank so deep.
But yet might rise again and be a man!

Dost thou behold thy lost youth all aghast?
Dost reel from righteous retribution's blow?
Then turn from blotted archives of the past
And find the future's pages white as snow.

Art thou a mourner? Rouse thee from thy spell!
Art thou a sinner? Sins may be forgiven;
Each morning gives thee wings to flee from hell;
Each night a star to guide thy feet to heaven."

News
Of Institute and Related Activities



Did you ever take a swim a mile up in the air? This is the famous mile-high beach at Lake Tahoe, California

Will You Take
"Your Vacation at the Lake Tahoe Convention"?

A TECHNICAL PROGRAM second to none, in which many essentials of present-day demands upon electrical engineering will be set forth and emphasized; a diversive program of which golfing, dancing, feasting, outdoor sports and a multiplicity of other delighting holiday occupations will be the happy ingredients—these are some of the things in store for those who will heed the call and follow the injunction to "Make your vacation include the Tahoe convention;" joys which shortly will be linked irrevocably with recollections of the Institute's twentieth Pacific Coast convention to be held August 25-28, 1931, now bearing high promise of being "the best one ever." And who will not enjoy the climax of Wednesday evening August 26, with a real barbecue followed by a general meeting and subsequent entertainment?

Technical Program

With L. F. Leurey (M'27) of San Francisco in the chair, the technical sessions will open with the presentation of three papers devoted to the profession in industrial application. The second session presided over by S. J. Lisberger (M'11) chief engineer in charge of the division of electric distribution and steam engineering, Pacific Gas & Electric Company, will offer an interesting and instructive collation of facts on a-c. networks, the Mokelumne River development (by Mr. Lisberger's own company), line control of interconnected networks, and "tuned" power lines. Wednesday, August 26, with C. E. Fleager (F'26 and vice-president) chairman, will be given over to a new and detailed study of the ever active subject, communication; on this occasion from both community and intercontinental standpoints. In the evening, convention guests will be afforded the pleasure of listening to C. E. Grunsky, internationally known president of the American Engineering Council, who will address the convention concerning "business and economics," a subject never more vital than at the present moment.

The technical program will come to

fitting close with Friday morning's session on electrophysics and general subjects including cathode drops in arcs and glow discharges, the kindling of electric spark-over, snow surveys, and radio coordination; R. W. Sorensen (F'19) professor of electrical engineering, California Institute of Technology, presiding.

ENTERTAINMENT

As earlier paragraphs suggest, an ample program of entertainment has been searched out and perfected by diligent local committees. In addition to diversions already named, there will be held on Friday evening "A Night at Monterey," a gala celebration modeled after the Spanish fiestas of old. Tahoe Tavern and Lake Tahoe on the shore of which it is located are unexcelled for pleasures and beauty of surroundings. Tennis, swimming, golf, horseback riding, and an exceptionally fine bowling alley all are available within the Tavern grounds, while the Kit Carson Trail to the historic mining cities of Carson and Virginia City in Nevada offers a short, but ultra scenic trip. The usual tournament for the Fisken Cup, Pacific Coast A. I. E. E. golf trophy, will be played on the Tahoe course. The majority of interesting points may be visited with ease and comfort in less than a day's time for the round trip.

The ladies have been specially planned for of course; a boat ride to Emerald Bay, bridge parties, and automobile trips have been carefully arranged for all those interested in their participation. On the evening of Thursday, August 27, a short playlet will be staged "to provide fun for all"?

The "Night in Monterey" will be held for the most part upon the delightful and well-equipped beach and boardwalk, ably engineered by the management of the Tavern.

VACATION SUGGESTIONS

In line with the promise of the convention's part in vacation plans it should be remembered that Lake Tahoe is in the very heart of California's famous Sierra Nevada mountain range. In almost every direction trips upon the lake offer an entry into splendid mountain scenery. Yosemite Valley, the historic Mother Lode gold mining country, Sequoia and General Grant National Parks, and other attractive spots are daily reached by good roads from the main highways in central and southern California. Members coming from or through Oregon and Washington will find Crater Lake, the Oregon Caves, and the Coast highway through the famous redwood belt delightful and recreative.

Attractive convention rates will be made available to members and guests at Tahoe Tavern for the entire week of August 23 to accommodate those wishing to devote a few uninterrupted days to pure diversion.

REGISTRATION AND HOTEL ACCOMMODATIONS

A general information and registration desk will open in the lobby of the Tavern Monday, August 24, and delegates and guests are requested to call there as soon after arrival as possible to obtain badges and news of convention schedule. The following fees covering registration, banquet, all scheduled events, and greens fees for the golf tournament will be in effect:

Members and men guests....	$5.00
Ladies.....................	3.00
Student members...........	1.00
Student guests..............	2.00

Tickets for the Thursday evening banquet are for only those registering for the convention; this applies to members, men and women guests, enrolled students and student guests. Tahoe Tavern is offering special convention rooming rates to Institute members and their families attending the convention. Many of the exceptionally large rooms are suitable for groups of four or five, and better to accommodate the unusual number of persons expected the management hopes that those who care to take advantage of this club arrangement will make up their own parties and thus simplify the question of hotel space allotment. Convention rates including meals will be as follows:

Room or small suite with bath (shared by 1, 2, or 3) per person per day............	$8.00
Room or suites with bath (shared by 4 or more) per day per person............	7.50
Room without bath, per person per day..............	7.00

All reservations must be made through the hotel committee by means of the regular hotel reservation blank provided; registrations made direct with the Tavern will not be recognized to benefit by convention rates. Order of receipt will establish precedence of choice of accommodations, etc.

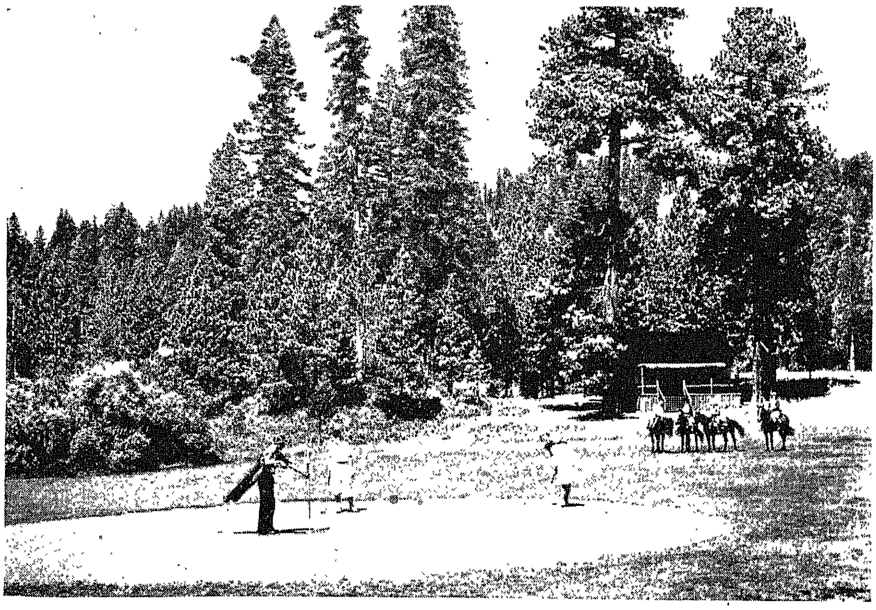
THE FISKEN TROPHY

The John B. Fisken Cup, much coveted golf trophy, is awarded annually to the best tournament score among members of the Pacific Coast Sections from 18-hole medal play at handicap. Many other prizes also will be awarded, all of which should make the tournament a feature attraction to any enthusiastic registered delegate or guest. No greens fees will be charged for the tournament, but specific information establishing handicap, etc., should be returned with the registration card.

TRANSPORTATION

Excursion rates are available from all points, railroad service to Lake Tahoe being provided by the Southern Pacific Company via its Overland Route. Spe-

Tahoe Tavern, headquarters of the forthcoming Pacific Coast convention



The annual tournament for the John Fisken cup will be played among the pines of the majestic "High Sierra"

cial routing information for making the trip by auto travel through most historic and scenic territory is made available by The Pacific Gas & Electric Company which will arrange to have its local representatives along all routes to the Lake to furnish specific information and render any possible service in case of emergency.

Committees

General convention committees and officers serving in the various departmental divisions of convention activities are as follows:

Chairman, A. W. Copley (F'26); vice-chairman, P. B. Garrett (M'30); both of Westinghouse Electric & Mfg. Company, 1 Montgomery Street, San Francisco, Calif.; secretary, E. F. Maryatt (M'27) of the Pacific Gas & Electric Company, 245 Market Street, San Francisco, Calif. Committee chairmen include A. G. Jones (A'07) *entertainment*; E. A. Crellin (F'28) *finances and hotel*; A. V. Thompson (A'23) *golf;* F. R. George (M'25) *inspection trips;* W. C. Heston (M'20) *publicity;* M. S. Barnes (A'18) *registration;* C. E. Fleager (F'26 and vice-president) *reception;* D. I. Cone (M'24) *technical program;* S. G. Palmer (A'15) *student activities;* P. Lebenbaum (M'13) *transportation;* and Mrs. Hector Keesling, *ladies' entertainment;* assisted by C. E. Carey (M'25), H. B. Carpenter (F'18 and vice-president), J. N. Chamberlain, L. B. Fuller (A'03), L. F. Fuller (F'23), A. V. Guillou (M'27), J. Hellenthal (M'23), H. W. Hitchcock (M'27), G. L. Hoard (A'19), A. H. Kruel, P. J. Ost (M'23), W. C. Smith (M'26), and L. A. Traub (A'28), members of the local committee.

Technical Program

Tuesday, August 25

10:00 a. m. Industrial Applications—L. F. Leurey, chairman.

Electrical Power in Wood Products Industry, by C. E. Carey and K. L. Howe, Westinghouse Electric & Mfg. Company, Seattle, Wash.

Application of Electricity to Oil Field Operation, by H. C. Hill and J. B. Selegue, Los Angeles

Correlation of Induction Motor Design Factors, by V. Hoover, Teaching Fellow in E. E., California Inst. of Tech.

2:00 p. m. Power Transmission and Distribution—S. J. Lisberger, chairman

Economics of A-C. Networks for Secondary Distribution, by S. B. Clark, Portland, Ore.

The Mokelumne River Development of the Pacific Gas & Electric Company, by E. A. Crellin, E. M. Wright, and B. D. Dexter, Pacific Gas & Elec. Company, San Francisco, Calif.

Tie-Line Control of Interconnected Networks, by C. A. Powel, Westinghouse Elec. & Mfg. Company, and T. E. Purcell, Duquesne Lt. & Power Company, Pittsburgh, Pa.

Tuned Power Lines, by H. H. Skilling, Stanford University

Wednesday, August 26

9:30 a. m. Student Technical Session No. 1

2:00 p. m. Communication—C. E. Fleager, chairman

Intercontinental Telephone Service, by J. J. Pilliod, engineer, American Tel. & Tel. Company, New York, N. Y.

Electrical Solutions of Problems of Regular Scheduled Flight, by C. F. Green, Schenectady, N. Y.

The San Francisco–Los Angeles Section of the Pacific Coast Telephone Cable Network, by E. M Calderwood, San Francisco, and D. F. Smith, Los Angeles, both of the Pacific Tel. & Tel. Company

Electrical Sound-Absorption Measurements, by A. L. Albert and W. R. Bullis, Corvallis, Ore.

Evening

Barbecue dinner

Address by C. E. Grunsky, president of American Engineering Council "Business Cycles and Some Economic Problems"

General meeting followed by entertainment

Thursday, August 27

8:00 a. m. Student Breakfast and Conference

Afternoon

Sports

Evening

Banquet and playlet

Friday, August 28

9:30 a. m. Electrophysics and General Subjects—R. W. Sorensen, chairman

Cathode Drop in Arcs and Glow Discharges, by S. S. Mackeown, California Institute of Technology, Pasadena, Calif.

The Kindling of Electric Sparkover, by C. E. Magnusson director of engineering experiment station, University of Washington, Seattle

Snow Surveys, by H. P. Boardman, professor of C. E., director of engineering experiment station, University of Nevada, Reno

Radio Coordination, by H. N. Kalb, Great Western Power Company, and C. C. Campbell, Pacific Gas & Electric Company, San Francisco

Irrigation Waste to Run Texas Plant

A hydroelectric plant to be built by the Central Power & Light Company near Eagle Pass, Texas, will utilize waters returned from the Maverick County Irrigation District No. 1, after they have been diverted for irrigation purposes and carried back by a supply canal to penstocks.

Excavations for the power house of this plant were started May 23, 1931; it is expected that the plant will be ready for operation early in 1932. The generators will be of 3,500 kw. 6.9 kv. umbrella type, the power produced to be transformed to the higher voltages in an adjacent substation. A 66-kv. line coming from the East supplies power for construction now and will be used later to carry power to the operating company's other points of distribution. During the irrigation season the river flow amounts to approximately 1,000 sec-ft. but at certain other seasons it reaches a 1,500 sec-ft. volume—*Wendell C. Fowler, San Antonio Section Correspondent.*

Asheville Convention Closes Busy Institute Year

WITH more than 500 persons in attendance the Asheville convention proved a fitting climax to a busy year. Essentially every District and active Section throughout the United States and Canada and including Mexico City, were represented It was of particular interest to note the high percentage of women guests who attended from distant points giving color and lending charm to an affair already under the spell of hospitality so typical of the Old South.

IMPORTANCE OF DISTRICT MEETINGS STRESSED

In a prelude to his final formal address before the Institute President Lee emphasized again his fervent wish to "Take the Institute to the members instead of trying to bring the members to the Institute." In this connection he emphasized the increasing value of District meetings, urged every effort to develop them, and outlined current progress in that direction. President Lee also called attention to the great value of the younger members to the Institute and of the Institute to the young electrical engineer, urging a greater participation on the part of the younger men. In his formal address, full text of which appears elsewhere in this issue, he sounded a challenge and a distinct note of encouragement to engineering students.

DELEGATES SESSIONS WELL ATTENDED

Two particularly well attended sessions of delegates, officers, and members were held at which several subjects of particular import to Institute members were rather fully discussed. These included the licensing of engineers, membership problems including transfer qualifications, and Section and student Branch operating problems. More concerning all of these subjects will be presented in ELECTRICAL ENGINEERING as the various committee studies and reports are completed. Technical sessions all were very well attended, attendance being enhanced perhaps by the fact that many of the sessions were held on the open verandas of the Grove Park Inn overlooking the North Carolina mountain scenery. A brief outline of the several papers presented is given in the paragraphs that follow; discussion will be reviewed in a subsequent issue.

Interconnections Discussed and Evaluated

RECOGNITION of some of the technical problems involved in the present-day trend toward mergers and large cooperative undertakings in the field of the electric service company, an entire session of the Asheville summer convention was devoted to a symposium of four papers on this general subject.

In his paper relating to the classification and evaluation of interconnection services A. E. Bauhan (M'17) of the Public Service Electric & Gas Company, Newark, N. J., defined his interpretation of the word *interconnection* as meaning the physical tying together of two or more independently owned or separately managed electric systems for the purpose of realizing financial benefit or service improvement through the interchange of power.

Under the heading of service classification the author listed emergency service, load diversity, firm power, storage power, intra-company use, economy flow, and unintentional flow. He expressed the hope that these seven suggested classifications would form the basis of discussion and experiment which would lead eventually to a generally acceptable classification and nomenclature.

ECONOMIC EVALUATION

After defining and describing these classifications in some detail, Mr. Bauhan launched into a discussion of interconnection service evaluation, stating that such evaluation represented the economic basis upon which the desirability of a proposed interconnection should be made. He stated that the services previously mentioned may be evaluated as to capital cost by determining the aggregate saving in the cost of generating capacity, and then comparing the result with the capital cost of the interconnection itself.

Stating that "interconnection is only one of the many factors contributing to the accomplishment of the purpose of the electric utility industry," G. M. Keenan (F'29) superintendent of the Penn-New Jersey Interconnection (Hazleton, Pa.) pointed out that the "possibilities of interconnection can be realized only when the system is effectively developed and operated."

DIVERSE INTERESTS OF PARTICIPANTS MUST BE COORDINATED

Mr. Keenan emphasized the limiting feature represented by the fact that while interconnected systems operate as a unit, the companies owning them have diverse interests which must be sufficiently coordinated to make available to all participants the maximum benefits to be realized by interconnection. Mr. Keenan stated also that interconnection development usually tends to reduce generating costs at the expense of increased transmission costs and hazards, concluding that "possibly there are some limits to the size of the interconnected system and the degree of coordination desirable between ownership."

The interconnected system representing ten independent operating companies of western Pennsylvania, eastern Ohio, West Virginia, and Maryland, were described at some length by H. S. Fitch (A'18) of the West Penn Power Company, Pittsburgh, whose paper reflected the operating practise and experiences of that group. He described the territory served by these companies and outlined the benefits derived by the interconnection as including a reduction in spare capacity, investment and operating economies effected through (1) dovetailing of construction programs; (2) joint financing of power stations and transmission lines; and (3) noteworthy protection of service continuity.

DISADVANTAGES MORE THAN OFFSET BY BENEFITS DERIVED

E. W. Dillard (M'30) and W. R. Bell (A'15) of the New England Power Engineering & Service Corporation, Boston, Mass., described in some detail the various practical problems involved in a typical New England interconnection involving systems in parts of six states. After outlining the history and development of the various interconnections, the authors gave as the objectives of their system the following:

1. The absorption of surplus hydro power from systems generating largely from unregulated hydro sources.
2. The absorption of large quantities of surplus steam with resultant good load factor on relatively high-grade steam plants of adjacent systems.
3. Arrangements for the purchase of surplus steam capacity in various stations which resulted in a certain amount of firm capacity.
4. The sale or purchase of firm power.

The authors outlined in some detail the benefits derived from these various factors, described the contractural relations entered into in the various cases, and pointed out certain disadvantages and difficulties encountered. They stated definitely, however, that they "do not believe that any disadvantages have come about in any New England interconnection that are not offset entirely by benefits derived."

Transients Important in Electrical Machine Design

ELECTRICAL machinery and its design and operating characteristics, always of interest in Institute conventions, were no exception at Asheville. This time the subject of electrical transients seemed to dominate in all presentations and discussions.

The problem of reestablishing excitation of a loaded alternator operating in parallel with others was discussed at some length by D. D. Higgins (M'27) and E. Wild (A'27), both of the Commonwealth Edison Company, Chicago. The authors described tests performed with large turbine-generators operating under load, and gave a résumé of various answers to a questionnaire bearing upon the phenomena accompanying the interruption and reestablishment of a generator's d-c. excitation. As a result of their investigation the authors conclude that the reexcitation of a generator without removing it from the bus is a justifiable and safe operating procedure and one which will restore all conditions to normal in the shortest time.

REACTANCE AND TIME CONSTANTS CALCULATED

L. A. Kilgore (A'29) of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., presented a highly mathematical dissertation pertaining to a method of calculating reactance constants and time constants, as they affect transient characteristics of synchronous machines. The author pointed out that recent theoretical advances have introduced many new constants; also that most of the discussions on such constants published previously have been concerned with the *application* rather than the *calculation* of the values involved. In his paper Mr. Kilgore calculated the more significant constants and gave comparisons between tests and calculated values to support the accuracy of his method. In two extended appendices he gave formulas for salient-pole machines and turbine-generators, and pointed out that because of differences in construction many of the formulas for turbine-generators are different from those for salient-pole machines. He discussed the more important differences.

As a companion paper to Mr. Kilgore's, S. H. Wright (A'29) also of the Westinghouse Company presented an extensive treatise descriptive of the determination by test of synchronous machine reactances, resistances and time constants. The author emphasized the practical side of the situation basing his statements and conclusions upon observations made from many tests and their results. Mr. Wright considered three classes of synchronous machines—turbine-generators, salient-pole machines with dampers, and salient-pole machines without dampers. In his tests the author achieved saturation effect under short circuits by applying short circuits to machines operating at rated voltage. He discussed in some detail the more important of the variable saturation effects, and by defining certain saturation and other values attempted to provide a definite basis for the practical specification of machine constants.

TRANSFORMER TRANSIENTS AFFECTED BY MANY FACTORS

An essentially mathematical study of transient voltages in transformers and similar equipment was presented by L. V. Bewley (A'27) of the General Electric Company, Pittsfield, Mass. Mr. Bewley devoted his major effort to showing the effects on voltage distributions of wave shape, circuit constants, and neutral impedances, and in describing methods by which the voltage distributions may be controlled or varied. He derived a general differential equation for a circuit consisting of distributed self- and mutual-inductance, series and shunt capacitance, series resistance and conductance along the stack to ground. The author presented (1) numerous solutions of his equation covering various sets of conditions; (2) equations corresponding to many different applied waves showing the effects of wavelengths, wave front, etc.; (3) equations for calculation of potential difference or voltage gradient between points in windings; and (4) tables showing the influence of various circuit constants on wave characteristics.

In describing field transients in magnetic systems, Ernst Weber (A'31) of the Brooklyn (N. Y.) Polytechnic Institute gave a comprehensive mathematical solution of the situation arising from the sudden application of a d-c. voltage through an electromagnetic circuit containing a partly laminated and partly solid iron core with an air gap. Ranging in mathematical manipulations from Maxwell's field equations for eddy currents and magnetic field in an iron core to Heaviside's operational calculus, the author achieved results which he expressed by means of a time constant of the magnetic field. In discussing the practical application of his results the author gave a numerical example and called attention to the effectiveness of quick response excitation for improving electric system stability under short circuit conditions, particularly where large synchronous generators are involved.

Efficient Communication Facilities Required for Successful Operation

REFLECTING the important position occupied by communication facilities in the successful operation of a modern electric light and power system, a symposium of five papers dealing with important phases of the subject occupied one entire technical session of the Asheville convention. Nine different authors collaborated in the preparation of these papers representing some five different power systems and three different divisions of the Bell Telephone System.

In practically all cases the three major divisions of communication service that received specific attention were those pertaining to (1) operating activities including dispatching, plant and substation operation, line patrol and repairs; (2) customer service activities including new installations, disconnections, transfers and service complaints; and (3) administrative activities including executive, sales, and business functions as differentiated from the service functions.

PRINCIPAL REQUIREMENTS OUTLINED

Fundamental considerations underlying the planning and providing of adequate and economical communication services for electric utilities were rather fully outlined and briefly discussed in a paper prepared by R. N. Conwell (F'31) of the Public Service Electric & Gas Company, Newark, N. J., G. M. Keenan (F'31) superintendent of the Penn-New Jersey Interconnection, Hazleton, Pa., C. F. Craig (M'27), special representative of the American Telephone & Telegraph Company, New York, and E. C. Briggs of the Ohio Bell Telephone Company, Cleveland. These authors described the normal workings of an electric utility as being so divided that all three classes of communication service mentioned in the preceding paragraphs are required. In enlarging upon the subject of communication facilities for operating activities, they stated that such facilities needed to be:

1. Easy to operate and capable of establishing prompt communication connection.
2. Available at times when generating and distribution facilities are in trouble.
3. Of sufficiently good quality to avoid misunderstandings and to permit conversations to be carried on with ease.
4. Adequately protected from the safety standpoint but not to a degree that would interfere with communication service during electric service difficulties.
5. Of sufficient capacity to obviate serious delay even under emergency conditions.

Leased Lines Preferred to Carrier Systems

E. S. Bundy (M'30) of the Buffalo (N. Y.) Niagara & Eastern Power Corporation, described the communication facilities of the western division of the Niagara-Hudson system. He characterized the modern tendency of interconnecting electric generating and transmission systems as leading to systems covering "such large areas that the communication lines have become almost as important as the power lines themselves."

Mr. Bundy described the communication requirements of his system which include remote metering, system dispatching, load supervision, commercial business, and ordinary interdepartmental communication. Perhaps the most important communication service in that system is provided by lines leased from the telephone company, arranged in some cases so that conferences involving several persons may be held over the lines. Single-frequency duplex carrier-current installations providing two-way communication between eight of the more important stations on the consolidated system supplement the line service. Under normal operating conditions leased lines are used in preference to the carrier system because of the better quality of transmission.

A description of the communication needs of a power company serving a large metropolitan area was given by P. B. Juhnke (M'20) of the Commonwealth Edison Company, Chicago. Detailed information pertaining to load dispatching problems on his system were discussed, and the use of remote metering facilities as an effective aid in conducting load dispatching operations was described. On this system the technical group in the load dispatching office is in direct private wire communication with all generating and distribution stations, and with most substations. In describing his remote metering system Mr. Juhnke mentioned that metallic telephone circuits now are used exclusively but stated that since telemetering impulses now can be transmitted over carrier-current communication systems, the usefulness of such carrier systems has been enhanced materially.

Coordinated Systems most Economical

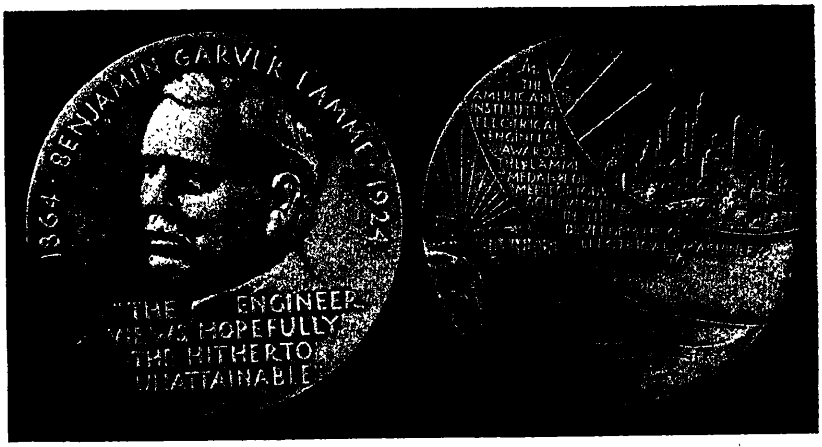
C. A. Booker of the New England Power Association, Boston, and M. E. Clark of the New England Telephone & Telegraph Company, Boston, described at some length a cooperative study of power system communication conducted jointly in New England by the power company and the telephone company. The problems there encountered involved a survey of existing communication facilities in the several districts effected, the determination of present and future communication requirements, and the analysis of these requirements to ascertain what improvements, changes, or additions should be made. Coordination of existing facilities both on the Bell system and on the Power Association's various private lines was the watchword of the joint investigation.

Switching from the communication problem of the relatively closely knit interconnected system to that of the relatively far flung interconnected system, E. C. Stewart of the Arkansas Power & Light Company, Pine Bluff, Ark., described the communication system in use on the Arkansas - Louisiana - Mississippi Interconnected Power System. Long distances between stations are the regular order of affairs on that system, and as a result carrier-current telephone equipment is used to a large extent, the longest distance so served being 459 mi.

After outlining the history of development and describing the problems incident to the development of the carrier-

---

"The Engineer Views Hopefully the Hitherto Unattainable"



BENJAMIN GARVER LAMME
1864-1924
"THE ENGINEER VIEWS HOPEFULLY THE HITHERTO UNATTAINABLE"
THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS AWARDS THE LAMME MEDAL

SUCH is the message of the Lamme Medal established by a bequest of Benjamin Garver Lamme, chief engineer of Westinghouse Electric & Manufacturing Company, who passed away July 8, 1924, after a life of professional usefulness. According to provisions of the bequest, a gold medal accompanied by a replica in bronze goes in award each year to a member of the Institute "who has shown meritorious achievement in the development of electrical apparatus or machinery." William J. Foster, D. Sc., consulting engineer (retired) of the General Electric Company, Schenectady, N. Y. was this year's recipient (see p. 230, Electrical Engineering, March 1931). A similar bequest was made by Mr. Lamme to Ohio State University, by which annual award is made to a graduate from any of its engineering branches "for meritorious achievement in engineering or the technical arts;" while a third medal is awarded by the Society for the Promotion of Engineering Education "for accomplishment in technical teaching or actual advancement of the art of technical training." The first Lamme Medal to be awarded by the Institute (1928) was given to Allen B. Field (F'13) consulting engineer, Manchester, England; the second to Rudolph E. Hellmund (F'13) chief electrical engineer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. C. E. Skinner, assistant director of Engineering, Westinghouse, received this year's award from Ohio State. (See p. 519 of this issue.)

current system, the author related some operating experiences. He said "the carrier-current installation on the interconnected system, supplemented by the use of toll service, and one or two leased or specially arranged circuits, is primarily for use by the dispatcher, but considerable business traffic is handled by the dispatching force outside of any rush period."

Automatic Control is Proving its Merit

CONCERNED with the general subject of automatic equipment five papers were presented at an Asheville session. Two of these dealt with the details of supervisory systems for electric power apparatus, one dealt with automatic combustion control, and two presented rather comprehensive outlines of actual operating experience with automatic and supervisory control equipment.

R. M. Stanley (F'23) of the Byllesby Engineering & Management Corporation, Chicago, Ill., described briefly the miniature switchboard supervisory automatic control equipment installed at the Ohio Falls Hydroelectric Station at Louisville, Ky., and gave a résumé of three years' operating experience with that equipment. Mr. Stanley gave the engineering reasons for the adoption of miniature supervisory switchboard and automatic control as being a desired reduction in capital expenditure, and reduced fixed and operating charges. As a result of his experiences he has concluded that automatic devices greatly enhance the services of a capable operator, and produce better station operation than would be possible by manual system of control alone.

Inspection and Maintenance Important Items

In a jointly prepared paper Garland Stamper (A'25) of the Columbia Engineering & Management Corporation, Cincinnati, Ohio, and F. F. Ambuhl (M'26) of the Toronto Hydro-Electric System, Toronto, Ont., Canada, described their respective operating experiences with automatic station and supervisory equipment. Mr. Stamper stated that the Columbia system has had automatic and semi-automatic stations of various types in operation for the past ten years, and as a result of experience stated emphatically that the degree of satisfaction secured in the operation of any type of automatic equipment is directly dependent upon the quality of inspection and maintenance.

Mr. Ambuhl reported that on the Toronto system automatic controls have given fairly satisfactory results and the supervisory controls have given excellent results, especially the cable-type supervisory." Relay failures constitute the chief source of trouble mentioned.

An a-c. supervisory control system devised to accomplish all that the more common d-c. supervisory systems now do, was described by O. K. Marti (M'27) of the American Brown Boveri Company, Inc., Camden, N. J. The equipment was said to be independent of interruptions in the a-c. supply at stations where it was installed, since it depends upon a small motor-generator set driven from the station battery. For this system five wires between stations are required, two being common supply lines, one a synchronizing wire, one a control wire, and one an indication wire.

Centralized Control Important in Railway Electrification

The Pennsylvania Railroad in its electrification in and around Philadelphia has made use of two installations of supervisory control for the remote operation of high-voltage a-c. step-down substations supplying energy to its traction system. The equipment used and the system involved were described by C. P. West (M'28) of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, and H. C. Griffith of the Pennsylvania Railroad Company, Philadelphia, who stated that the normal practise of the railroad has been to install substation control in signal towers adjacent to substation location, because most substations have been near 24-hr. signal towers. Conditions are changing, however, and the system is expanding beyond the normal operating radius of signal towers. The authors state that from the many advantages of centralized control, this method is destined to play an increasingly important part in future railroad electrification.

Automatic Systems for Accurate Combustion Control

Since heat-power plants have increased so enormously in size, and combustion practise reduced so nearly to an exact science, automatic combustion control has become an economic necessity according to C. H. Sanderson (F'18) and E. B. Ricketts of the New York Edison Company, who presented a joint paper describing several of the more important automatic combustion control systems. The authors cited as being among the important advantages: (1) the uniform loading of all boiler units; (2) instant response to changes in load; (3) correct proportion of fuel and air supply at all times; and (4) a ready means of providing for safety in operation through sequence interlocking of auxiliary equipment.

High-Voltage Cable Practise Continues to Advance

IN an Asheville session devoted exclusively to the subject of cables, the discussions presented ranged all the way from the most highly theoretical to the most practical. Three research workers, four manufacturers, and one prominent operating man presented papers representing their various fields of interest and thus contributed to a better general understanding of the subject.

Results of still further study on the open question hinging on the influence of residual air upon cable insulation life, were presented in a paper by J. B. Whitehead (F'12) and F. Hamburger, Jr. (A'26) of Johns Hopkins University, Baltimore, Md.,—their third A. I. E. E. paper on that subject. As a result of their intensive investigation, the authors have concluded among other things that:

1. The life of impregnated paper insulation increases steadily with a decrease in the amount of residual air.

2. For impregnating pressures above 2.5 cm. the life decreases rapidly with increasing pressure of impregnation. For pressures below 2.5 cm. the results show an increase of life of from 10 to 50 per cent between 2.5 cm. and 2 mm. impregnating pressure.

3. For impregnating pressures below 2.5 cm., normal variations in material and structure, particularly in the tightness of the structure, may offset the increased life due to decreasing the pressure of impregnation.

4. Cable compound deteriorates if it contains only a small amount of air even though kept in sealed containers, at room temperature. To avoid deterioration air should be entirely excluded.

5. Flat power-factor voltage curves and the absolute value of power factor should not be accepted as indications of long life.

6. Power-factor rise due to the initial application of voltage during a life test is indicated as a possible criterion of insulation life.

7. A very satisfactory type of sample and a reenforced end for accelerated life tests have been developed.

8. Narrow variations in the quality of both paper and oil may cause wide differences in the electrical characteristics and in the lives of the impregnated products.

INSULATION VARIABILITY LIMITS ALLOWABLE OPERATING STRESSES

M. C. Holmes (A'26) of West Virginia University, Morgantown, presented a paper describing a method of analyzing the effect of insulation variability in the determination of breakdown voltages and allowable operating stresses. He emphasized the necessity of considering the variability as well as the so-called strength of insulation and quoted terms of allowable operating stresses and failures in support of his contentions. He developed and discussed the application of a general equation, giving in terms of two parameters the breakdown voltage and the number of failures to be expected, the mean breakdown voltage, and the variability of insulation.

Oil-filled cables and accessories were described by R. W. Atkinson (F'28) and D. M. Simmons (F'28) of the General Cable Corp., New York, N. Y., who defined the term "oil-filled" as being ordinarily understood to indicate a cable in which the compound is of such viscosity as to be fluid at all operating temperatures.

General theory and some of the outstanding characteristics of oil-filled cable practise were discussed in some detail by G. B. Shanklin (M'29) and F. H. Buller (M'29) of the General Electric Company, Schenectady, N. Y.

BETTER CABLES AT LOWER COSTS PREDICTED

An illuminating and fairly comprehensive outline of economic high-voltage cable practise based upon extensive research and intensive practical application was given by D. W. Roper (F'14) of the Commonwealth Edison Company, Chicago. In illustrating the salient points of his discussion Mr. Roper presented numerous data and diagrams. He called upon utility companies to improve their standards of design and workmanship to keep pace with cable improvements effected by manufacturers. He stated definitely that in his opinion the present rate of improvement in the art of high-voltage cable practise would continue in succeeding years, and further in prediction said that:

1. Cables of all types and voltages will be operated at maximum temperature of from 85 to 90 deg. cent. without fear of deterioration.

2. Extensive oil reservoirs and accessories on oil-filled cable will be eliminated.

3. An installation of oil-filled cable will be no more complicated than a present day installation of ordinary cable.

4. Cable of subnormal quality will be eliminated by factory tests.

5. Initial costs per kva. of 66-kv. cable completely installed will range from 30 to 40 per cent lower than the present cost of ordinary cable.

6. Cable failures due to all causes will not exceed one per 100 mi. per year.

Standardization of Units an International Problem

ELECTRICAL units, their modernization, international standardization, precise determination, and proper application is a subject occupying a great deal of the time of many learned technologists throughout the world. Advancement in the art and science of electrical engineering has given rise to a rather concerted study of electrical units along the lines as just indicated, to say nothing of international effort to arrive at a logical and representative nomenclature. Reflecting the importance and timeliness of the subject, the fourth session of the Asheville convention was devoted to a symposium of four papers on various phases of the subject.

H. B. Brooks (F'31) of the Bureau of Standards, Washington, D. C., treated at some length the unit of electrical resistance, going into its past history, and outlining impending changes. The author described the mercury ohm as having been so long legalized as a material standard of resistance that it is regarded widely as a permanent institution of relatively precise proportions, but stated that practically it is obsolescent because of the technical difficulties attending its use. The author further characterized the mercury ohm as a necessary but expensive evil holding its place because formerly it could be reproduced more precisely than could the agreement between the results of absolute determinations of the ohm. He concluded his presentation saying that the technique of absolute determination has improved until now it may be said to be at least on a par with the mercury ohm as to reproducibility. Consequently this method should be used to obviate the laborious and time-consuming effort of high grade men now going into repetitions of mercury ohm determinations.

STANDARDS MUST KEEP PACE WITH ADVANCES IN EQUIPMENT

In a discussion of electrical units and their application, L. T. Robinson (F'12) of the General Electric Company, Schenectady, N. Y., emphasized the necessity of providing for the advancement of precise definitions and precision standards to keep pace with contemporary advances in equipment. In speaking of the importance of accurate measurements as far as scientific advance is concerned, he said "progress and improvement are made possible only to the extent that those interested in and working along the line of developing and improving measuring methods and instruments are able to anticipate the needs of those interested in the development and operation of systems, devices, and apparatus."

Pertaining to the international standard of electromotive force, and its low-temperature coefficient form, Marion Eppley (M'31) of the Eppley Research Laboratory, Newport, R. I., described at some length the great difficulty in achieving the physical conditions prescribed in the officially agreed upon fundamental definitions of certain electrical units. He described briefly several different types of so-called standard cells for reproducing physically a standard volt, discussing also various tests made on and the characteristics of the cells. He concluded definitely that his fifteen years of work on the cadmium cell have given him "ever increasing confidence in its reliability," even if it "is by no means foolproof."

LABORATORY POTENTIOMETERS DISCUSSED IN DETAIL

Information pertaining to the design of d-c. laboratory type of potentiometers was given by I. M. Stein (M'27) of the Leeds & Northrup Company, Philadelphia. The author treated his subject under the following ten headings: (1) early history; (2) factors affecting voltage range; (3) factors affecting potentiometer resistance; (4) low-voltage potentiometers; (5) analysis of potentiometer errors; (6) self-checking features of potentiometers; (7) galvanometer considerations; (8) comments on volt-boxes; (9) deflection potentiometers; (10) the potentiometer in industry.

Research Problems Vie with Cooperative Education

COOPERATIVE educational methods competed with transmission stability research problems for the attention of those attending the closing session of the summer convention.

D. C. Jackson, Jr. (F'30) of the University of Kansas, discussed in some detail the application of the cooperative method of instruction to engineering schools and polytechnic institutes. As constituting five important factors governing the application of the cooperative method to any given institution, the author considered (1) the size, (2) geographical location, (3) type of location, (4) method of support, and (5) organization of the institution. He discussed various methods of applying the cooperative plan and expressed the opinion that "no exact conclusion can be drawn concerning the general principles governing the installation of the cooperative method at an institution since the controlling conditions are so different in each case."

FACTORS AFFECTING THE EXTINCTION OF SHORT A-C. ARCS

The results of a study concerning the extinction of short a-c. arcs were discussed in a paper by T. E. Browne, Jr. of the Westinghouse Elec. & Mfg. Company, East Pittsburgh, Pa. Mr. Browne's findings as stated were:

1. That the arc space recovers the ability to withstand 100 volts or more within a few microseconds after a current zero, as predicted by Slepian's theory.
2. That the maximum allowable rate of voltage rise across the arc space which will just permit arc extinction, is much greater for very short arcs (1 cm. or less) than for longer arcs.
3. That the critical rate of voltage rise depends upon the electrode material and tends to vary as a decreasing linear function of the boiling point of that material.
4. That the higher-current arcs have a much lower critical rate of rise of voltage than the lower-current arc.

VACUUM TUBES SCORE AGAIN

A corona-tube voltage regulator designed to accomplish all of the functions of the ordinary vibrating type of regulator, and without the mechanical difficulties incident to the latter, was described by H. W. Dodge of the New Jersey Bell Telephone Company, and C. H. Willis (M'28) of Princeton University. The authors presented and described a circuit wherein a corona tube is used to regulate the output of a full-wave rectifier, the rectifier in turn controlling the excitation of a generator to give constant voltage. They presented very attractive performance curves covering the application of the apparatus to a 5-kva. generator under varying load conditions. The authors characterized the regulator as employing the same methods of compounding and line-drop compensation now in use and expressed the belief that the simplicity, compactness, high sensitivity, and quick response of the regulator offered important advantages.

LIGHTNING SURGES CAUSE ARCING FAULTS

Experimental studies of arcing faults imposed on a typical 75-kv. transmission system were discussed in a paper prepared jointly by J. R. Eaton (A'27) of the Consumers Power Company, Jackson, Mich., J. K. Peck (A'27) of the National Electric Light Association, New York, and J. M. Dunham (A'31) of the American Telephone and Telegraph Company, New York. High-voltage impulses simulating lightning were imposed upon an energized transmission line to cause flashovers. As a result of their observations the authors concluded that the probability of a lightning flashover causing a power arc is increased when power current is flowing past the flashover point, when the normal frequency voltage is increased, or when the normal insulation is decreased.

Effective arc resistance was described as being approximated by the ratio of the peak voltage to the peak current, the apparent power factor of the arc current and voltage being practically unity in most cases. The tests showed that arcs formed in a capacitive circuit are more persistent than those in inductive or resistive circuits, and indicated an average peak of about 300 volts per foot of arc length, for currents of about 100 amperes or more. Regarding system overvoltages arising from arcing grounds, the authors concluded the maximum to be approximately three times normal peak voltage from line to ground, and that it occurs on a sound phase and most frequently during the first cycle of the fault.

Minutes of Annual Meeting Held at Asheville June 22

The annual meeting of the American Institute of Electrical Engineers was held at the Grove Park Inn, Asheville, N. C., as the opening session of the annual summer convention, Monday morning, June 22, 1931. President W. S. Lee presided.

The annual report of the board of directors was presented in abstract by F. L. Hutchinson, national secretary. Printed copies were distributed to members in attendance and are available to any member upon application to Institute headquarters, New York. The report, which constitutes a résumé of the activities of the Institute during the fiscal year ending April 30, 1931, shows a total membership on that date of 18,334. In addition to the three national conventions and five District meetings, 1,628 meetings were held during the year by the local organizations of the Institute in the principal cities and educational institutions in the United States, Canada, and Mexico. The report will appear in full in the Quarterly TRANSACTIONS of the Institute.

The report of the committee of tellers on the election of officers of the Institute was presented, and in accordance therewith President Lee declared the election of the following members, taking office August 1, 1931:

President:

C. E. Skinner (F'12), assistant director of engineering, Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Vice-Presidents:

W. B. Kouwenhoven (M'22), professor of electrical engineering, assistant dean of the Engineering School, Johns Hopkins University, Baltimore, Md.

W. E. Freeman (M'27), head, department of electrical engineering, assistant dean of College of Engineering, University of Kentucky, Lexington, Ky.

Paul H. Patton (M'25), telephone engineer, Northwestern Bell Telephone Company, Omaha, Neb.

A. W. Copley (F'26), engineering manager, Pacific Coast district, Westinghouse Electric & Mfg. Company, San Francisco, Calif.

L. B. Chubbuck (M'26), switching equipment engineer, Canadian Westinghouse Company, Ltd., Hamilton, Ont.

Directors:

L. W. Chubb (F'21), director of Westinghouse Research Laboratories, Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

B. D. Hull (M'26), engineer, Southwestern Bell Telephone Company, Dallas, Tex.

H. R. Woodrow (F'23), electrical engineer, Brooklyn Edison Company, Inc., Brooklyn, N. Y.

National Treasurer:

W. I. Slichter (F'12 and national treasurer), professor of electrical engineering, Columbia University, New York, N. Y.

(These officers, together with the following hold-over officers, will constitute the board of directors for the next administrative year, beginning August 1: W. S. Lee (retiring president), Charlotte, N. C.; Harold B. Smith (F'13 and past-president), Princeton, Mass.; H. V. Carpenter (F'18 and vice-president), Pullman, Wash.; G. C. Shaad (F'13 and vice-president), Lawrence, Kans.; I. E. Moultrop (F'29 and vice-president), Boston, Mass.; H. P. Charlesworth (F'28 and vice-president), New York, N. Y.; T. N. Lacy (M'24 and vice-president), Detroit, Mich.; J. Allen Johnson (F'27), Buffalo, N. Y.; A. M. MacCutcheon (F'26), Cleveland, Ohio; A. E. Bettis (F'26), Kansas City, Mo. (terms expire July 31, 1932); J. E. Kearns, Chicago, Ill.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y. (terms expire July 31, 1933); A. B. Cooper (M'16), Toronto, Ont.; A. E. Knowlton (F'30) and R. H. Tapscott (F'29), New York, N. Y. (terms expire July 31, 1934).

President Lee then congratulated President-elect Skinner (F'12) upon his election and presented him with the president's badge. Mr. Skinner responded with a brief address, which was enthusiastically received.

The report of the committee on award of Institute prizes, as published in the June 1931 issue of Electrical Engineering (p. 448) was read by A. E. Knowlton, chairman of the committee of award, after which the prizes were presented by President Lee.

The Lamme medal for 1930, which, as announced in the March 1931 issue of Electrical Engineering (p. 230), had been awarded to W. J. Foster (F'16), of Schenectady, N. Y., was presented.

The annual presidential address was then delivered by President Lee, the subject being "Coordination—the Essence of Modern Engineering." (This address is published in full on p. 512 of this issue.)

Adjourned.

(Signed) F. L. Hutchinson,
National Secretary

"Who's Who in Engineering"

Engineers listed in the forthcoming edition of "Who's Who in Engineering" shortly will receive notification of the page upon which their listing occurs.

The publishers emphasize the fact that volumes of this compendium of engineering biographies will be available only to those placing reservations prior to publication, and urge prompt action on the part of any persons wishing to acquire the book.

Institute Policy Committee Appointed

At the May 19, 1931 meeting of the Institute's board of directors the question was raised—*should the Institute, with the object of enhancing the status of the engineering profession, devote more of its resources to non-technical activities, such, for example, as legislation, education, and the economic welfare of the engineer?*

The following resolution was adopted:

"Resolved: That the president be authorized to appoint a special committee on Institute policies for the purpose of studying the present and any proposed future activities of the Institute; this committee to invite and consider suggestions from any member, officer, or committee, and to make definite recommendations to this board regarding modifications of present activities and plans for any additional fields of work that the committee may deem desirable."

In accordance with this action, President Lee appointed the following committee:

Chairman, C. E. Stephens (M'22) (vice-president and northeastern district manager, Westinghouse Electric & Manufacturing Company, New York, N. Y.) director; present chairman of finance committee; member, committee on coordination of Institute activities, executive committee, U. S. National committee of the I. E. C., and the assembly of American Engineering Council.

Vice-Chairman, H. A. Kidder (F'29) (superintendent of motive power, Interborough Rapid Transit Company, New York, N. Y.) past-vice-president; present chairman, committee on engineering profession; member, board of examiners, law committee, assembly of American Engineering Council, and board of trustees of United Engineering Trustees, Inc.

H. P. Charlesworth (F'28) (vice-president Bell Telephone Laboratories, Inc., New York, N. Y.) vice-president New York City District; past-chairman, meetings and papers committee; chairman, committee on coordination of Institute activities; member, Edison medal, engineering profession, finance, Lamme medal, meetings and papers, and publication committees, and board of trustees of United Engineering Trustees, Inc.

F. L. Hutchinson (M'13) (national secretary, A. I. E. E.) member, committee on coordination of Institute activities, Edison medal, and publication committees, assembly of American Engineering Council, engineering societies library board.

J. A. Johnson (F'27) (chief electrical engineer Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y.) director; present chairman, membership committee; member, Edison medal, executive, electrical machinery, and research committees.

E. S. Lee (F'30) (assistant engineer General Electric Laboratory, Schenectady, N. Y.) present chairman, Sections committee; member, committee on coordination of Institute activities, and instruments and measurements committee.

E. B. Meyer (F'27) (vice-president United Engineers & Constructors, Inc., Newark, N. J.) director; past-chairman, meetings and papers, and finance committees; present chairman, law committee; member, committee on coordination of Institute activities, Edison medal, finance, publication, and power generation committees.

W. S. Rodman (F'28) (professor of electrical engineering, University of Virginia) vice-president, Southern District; student Branch counselor; member, Sections and electrophysics committees, education research committee of Engineering Foundation, and assembly of American Engineering Council.

C. F. Scott (F'25 HM'29) (head of department of electrical engineering Yale University), past-president; chairman, development committee 1919; member, Lamme medal, standards and student Branches committees, assembly of American Engineering Council; past-member, many other Institute committees.

This committee held its first meeting June 8 at Institute headquarters and directed that through this notice in Electrical Engineering the membership be invited and urged to submit through the national secretary any suggestions or criticisms relating to the present activities of the Institute; also regarding any additional activities which individual members may deem desirable.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Collinot, Marcel A., 88 Sherman Ave., Newark, N. J.
Cole, Will G., Box 222, Westwood, Calif.
Corriveau, F. M., General Electric Co., Schenectady, N. Y.
Falk, Victor E., 2422 Euclid Ave., Cleveland, Ohio.
Fyler, George W., Y. M. C. A., Schenectady, N. Y.
McDonald, I. M., 772 Pollokshaws Road, Glasgow, Scotland.
Nuber, Frank J., 3831 Rokeby St., Chicago, Ill.
O'Shea, V., Jr., 115 Broadway, New York, N. Y.
Sullivan, John E., 6320 Kenmore Ave., Chicago, Ill.
Tung, C. T., c/o Stone & Webster Engg. Corp., Hopewell, Va.

Personal

F. M. Feiker Appointed Commerce Director

The appointment of Frederick M. Feiker (M'15) managing director of the Associated Business Papers, Inc., New York, N. Y., to the office of director of the Bureau of Foreign and Domestic Commerce was announced May 29, 1931, by President Hoover. Mr. Feiker succeeds W. L. Cooper who is withdrawing to resume his former duties as commercial attaché at London, England.

Born at Northampton, Mass., Mr. Feiker received his degree of B. S. in E. E. from Worcester Polytechnic Institute, Worcester, Mass., in 1904. He has served as editor of *Factory Magazine* and *Electrical World*; chairman of the editorial board of *System* and *Factory*; and vice-president of the McGraw-Hill Publishing Company, Inc., New York, N. Y. During 1920-21 he was Acting Assistant Secretary of Commerce and served in the various capacities. Besides having been a member of the Institute for almost two decades, Mr. Feiker holds an active membership in the American Society of Mechanical Engineers and the Illuminating Engineering Society.

Harold B. Smith (F'13) past-president of the Institute and for many years head of the department of electrical engineering Worcester Polytechnic Institute, Worcester, Mass., resigned his educational chair there effective June 1931. As one well known in engineering and education Dr. Smith always has carried forth a multiplicity of duties in these fields. His share in Institute activities has been abundantly represented by service on several of its committees simultaneously, including: law 1920-21; electrolysis and student branches 1920-27; instruments and measurements 1921-22; educational 1922-27; sections 1922-28; Edison Medal 1924-26, 1929-30, 1930-31; research, coordination of Institute activities, and meetings and papers 1924-27; code of principles for professional conduct 1928-29; executive 1929-31; and public policy 1930-31. He was appointed also to the John Fritz Medal board of award for 1929-33, the U. S. national committee of the I. E. C., the Chas. A. Coffin Fellowship & Research Fund committee 1929-30, and the American Engineering Council 1930-31. It is his hope to resume professional practise.

F. V. Magalhaes (F'19) who left New York and his office as general superintendent of distribution and installation, New York Edison Company, to become vice-president of the Hall Electric Heating Company, Inc., now has been appointed general manager of his company in addition to his duties as vice-president. His professional career has been a busy one; during the past year he was vice-chairman of the Institute's committee on safety codes, an alternate representative for the Institute in the National Fire Protection Association (electrical department) and on the National Fire Waste Council; also a member of special subcommittee of the standards committee dealing with reactive power. The year previous he served at various times as a member of the Institute's board of examiners and the meetings and papers committee; was member and chairman of the A. I. E. E. committee on instruments and measurements. For several years was one of the Institute's representatives to U. S. National committee of the International Electrotechnical Committee.

H. L. Wills (A'20) inductive coordination expert as assistant to the vice-president and general manager of the Georgia Power Company, Atlanta, Ga., now has established a consulting engineering practise of his own, specializing in adjustment of relations between telephone, telegraph, railway signal, and automatic train control systems, including problems of electrolysis and radio interference. Mr. Wills was chairman of the Institute's Atlanta Section in 1921 and 1928, and has rendered much valuable service to the National Electric Light Association as a member of its inductive coordination committee (1923-27); chairman (1928-29). Mr. Wills has been active also in the association's joint operations with the Bell Telephone System (joint subcommittee on development and research, 1926-31) and with the American Railway Association's subcommittee on principles and practises (1929-31).

F. M. Denton (F'28) head of the department and professor of electrical engineering, University of Mexico, Albuquerque, N. M. has been awarded fellowship in the City and Guilds of London Institute, the highest distinction that institute confers. Only eleven of its several thousand graduates since the inauguration of its Fellow in E. E. degree have received it; it was awarded to Mr. Denton as one "of a limited number of Associates (ACGI) with not less than five years of actual practise and having contributed to advancement of the industry." The City and Guilds College (School of the University of London) is said to be the foremost of engineering schools in the British Empire.

D. Levinger (M'30) engineer of manufacture, Western Electric Company, recently was elected one of its directors, the youngest member of the company's board. Already he has served the company for 21 years and now as its engineer of manufacture heads a large force of trained engineers and scientists. He is a member of the Institute of Mining and Metallurgical Engineers, and has served three years upon its research committee; he also is a member of the American Society of Mechanical Engineers, the American Society for Steel Treating, and the American Association for the Advancement of Science.

R. F. Pack (M'12) recently elected president of the Northern States Power Company has been identified with the electrical industry since 1891 when he engaged as office boy with the Toronto Electric Light Company. He was instrumental in the affiliation between the Canadian Electrical Association and the National Electric Light Association in the affairs of which he has always remained active. He worked with B. Gherardi (F'12 and past-president) vice-president of the A. T. & T., in improving harmonious relations between these two great industries.

T. H. Clegg (M'21) who has been affiliated with the Philadelphia Rapid Transit Company as special engineer, on June 1, 1931, opened his own consulting offices at the same address, 1600 Walnut Street, Philadelphia, Pa. In the past, Mr. Clegg's work has been of a confidential nature appertaining to power investigations, and to the operation and management of power plants. For the past three years he has served the American Electric Railways Association on committees dealing with power contracts and mercury-arc rectifiers.

C. E. Skinner (F'12) assistant director of engineering, Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa., upon June 8, 1931, received the Lamme Medal annually awarded by Ohio State University to an alumnus "for meritorious achievement in engineering or the technical arts." Mr. Skinner has done much conspicuous professional work in many fields of electrical application. He has served the American Society of Testing Materials (1917-18), the Engineering Council (1917-19), and American Engineering Council (since 1923).

W. R. Whitney (A'01) vice-president and director of the research laboratory, General Electric Company, Schenectady, N. Y., was awarded the Franklin Medal of the Franklin Institute May 20, 1931. The award, which this year took place at Philadelphia, is made annually to "workers in physical science or technology without regard to country, whose efforts in the opinion of the administering committee on science and arts, have done most to advance a knowledge of physical science or its application."

Joseph O. Phelon (M'13) for 44 years identified with the Worcester Polytechnic Institute, Worcester, Mass., retired from the office of professor of electrical engineering June 1931. For several years after his graduation from that Institute, he taught in its physics department, but in 1896 he was transferred to the newly formed department of electrical engineering where he has served as full professor since 1907 and as head of the department in 1911-13. He now plans to make California his place of residence.

W. S. Gifford (A'16) president, American Telephone & Telegraph Company, New York, N. Y. has been elected a member of the board of trustees of Cooper Union, New York City, to succeed Thomas Snell, deceased. This continues a tradition of service to Cooper Union by men in the forefront of industry and public affairs.

W. F. Fenninger (M'22) who has been serving as supervisor of electric courses at the Rochester (N. Y.) Mechanics Institute, is now state supervisor of technical and cooperative education, with headquarters at Albany. In this capacity he visits the several high schools in which technical courses are given offering suggestions to bring them up to State standards or for maintaining these standards if already achieved.

M. K. McGrath (M'27) who has been serving as vice-president of the International Telephone & Telegraph Corporation, Aldwych, London, W. C. 2, England, left there June 6, 1931, to take up residence in America. His address for the present will be in care of the International Telephone & Telegraph Corporation, New York, N. Y.

L. C. Armitage (A'28) who has been industrial heating engineer for the General Electric Company, Schenectady, N. Y. has now become designing engineer for the Ajax Electric Company, Inc., at Philadelphia, Pa. where his principal work will be the design and development of a variable temperature electric decorating kiln.

R. D. Bean (A'21) formerly manager of the engineering development department of The Brown Instrument Company, Philadelphia, has been made chief engineer of that company. Mr. Bean's extensive field investigations cover many applications of measuring instruments.

F. J. Airey (A'19) division manager of the General Electric Supply Corporation at Los Angeles, Calif., has been elected chairman of the National Electric Wholesalers' Association. He has been 42 years in the business of electrical merchandising.

B. L. Robertson (A'26) assistant professor of electrical engineering, Pennsylvania State College, State College, Pa., has left the East to enter the department of electrical engineering of the University of California at Berkeley, Calif.

H. C. Wolfe (A'28) recently has become associated with the Empire Industries, Inc., Cleveland, Ohio, as its president. His work with the company will be the development of industrial application of chromium plate for engine parts, turbine blades, molds, and various tools and dies.

R. D. McCarter (M'09) who has been doing a consulting engineering business in New York City, has joined the European Gas & Electric Company, Aldwych, London, W. C. 2, England.

Obituary

H. Eugene Chubbuck (F'13) retired operating head of the Illinois Traction System, Inc., whose name is closely linked with the story of electricity and its application, died June 4, 1931 in Peoria, Illinois, after an extended illness. He was born in Utica, New York, and educated in the public schools of that city supplemented by one year at Whitestown Seminary and later a special course in chemistry and physics. In 1880 he returned to Whitestown as instructor in these subjects. He devoted the years 1881-1883 to shop practise in telegraph and philosophical instruments, the last year for the greater part being spent on electric lighting and testing machinery. In 1883 he engaged with the Thomson Houston Company as an expert and installed the first lighting plant at Pawtucket, R. I. The Narragansett Electric Company of Providence, R. I. next appointed him as its electrical engineer, a service occupying him for one year, and terminating in his return to special expert and construction work for Thomson Houston. In 1898 he joined the General Electric Company for special work and was given charge of its sales offices at Salt Lake City. He was the son of A. S. Chubbuck and grandson of S. W. Chubbuck, both well known to the profession for establishing the manufacture of telegraph machinery, and the building of some of the first instruments used. Mr. Chubbuck joined the Institute as an Associate four years after its organization, when the grade of Associate was the compulsory initial grade.

T. H. U. Aldridge (F'18) vice-president and general manager of the Shanghai Power Company, Shanghai, China, died suddenly on the 10th of May, 1931. A native of London, England (1874), his residence in China dates back to 1901 when he accepted appointment as municipal electrical engineer to the International Municipal Council of Shanghai. By the end of 1916 his staff had increased from three Europeans and 120 Chinese to 76 Europeans and 1,099 Chinese. As engineer-in-chief and manager of the municipal electricity department Mr. Aldridge was directly responsible to the electricity committee for both technical and commercial direction of undertaking as well as matters involving finance. He was responsible also for the general design and layout of two large power stations including all essentials of a central station light, heat, and power system. During his régime the system was converted from single-phase, 100-cycle, 2,000-volt generation and distribution to a modern 50-cycle system. The annual report of the Shanghai Municipal Council's electricity department (1917) attests the success of his undertakings.

Carlyle Kittredge (F'22) assistant to the vice-president of the Michigan Bell Telephone Company, Detroit, Mich., and for many years its chief engineer, died in the Harper Hospital that city May 23, 1931, the result of an operation for acute appendicitis. He was born at Mason, Mich., July 19, 1874. As past-chairman of the Institute's Detroit-Ann Arbor Section (1921) he has been specially active for its interests. He also was a member of the Detroit Engineering Society. In 1897 he was graduated from the University of Michigan with the degree of B. S. in E. E., and two years later joined the Electric Light & Power Company, Van Wert, Ohio, as its superintendent. In 1900 he engaged with the Central Union Telephone Company, doing special inspection work in Ohio, Indiana, and Illinois, ultimately becoming assistant chief engineer. On August 15, 1911, he joined the Michigan State Telephone Company as plant engineer, a position which he held until 1920 when he became chief engineer. At the time of his death he was secretary of the Wolverine section of the Telephone Pioneers of America.

Jay L. Stannard (M'29) chief engineer of the department of public utilities, City of Tacoma, Washington, died March 13, 1931 having been ill less than a month. He was a native of Chittenango, N. Y. (1866); after two years in common and high school at Shell Rock, Iowa, he spent two years at Cornell

College, Mount Vernon, Iowa. Until 1887 his time was occupied chiefly with a civil engineering practise. For the next ten years he acted as engineer for the contractor on several of the power and lighting projects of the Pacific Coast. Prior to his arrival in Tacoma (1923) Mr. Stannard had been identified with many irrigation, water works, and power plant developments along the Pacific Coast; the Grant Smith Company project in California, the Cedar River plant at Seattle, and the Bull Run plant at Portland. From 1912 to 1919 he was consulting engineer for the North Coast Power Company in Portland. At the time of his death he was serving his second term as president of the Tacoma Section of the American Society of Civil Engineers, which he had been instrumental in establishing.

William F. Callahan (A'23) engineering assistant, Western Union Telegraph Company, New York, N. Y., died May 31, 1931, at the age of forty. After the completion of studies in machine design, manual training and applied electricity at Pratt Institute, his first business connection (1910) was when he joined the Western Electric Company, New York, with which he remained as machine hand and inspector until 1913; then he became draftsman of Bramhall Deane & Company, Brooklyn, N. Y. In March 1914 he engaged with the Western Union Telegraph Company, New York City, spending three years as draftsman, followed almost immediately by appointment as engineering assistant, the position he held until his death. Mr. Callahan belonged to the Institute's New York Section, in which he was active.

Local Meetings

Utah Section and Branch Meet

The Utah Section and the University of Utah Branch held their annual joint meeting for the presentation of a student program on May 18. This was the last meeting of the Section for the present administrative year.

The following papers were presented by students:

Keying of Continuous-Wave Transmitters, by M. R. Johnson and L. K. Irvine.

Illumination of the University Campus, by L. D. Schroder and J. O. Carlston.

Stroboscopic Effects with Neon Glow Tubes, by Courtney Campbell.

Investigation of the Acoustics of Kingbury Hall, by Fred Lundberg and F. M. Neal.

Oklahoma City Section Meets with Branches

The annual joint meeting of the Oklahoma City Section and the student Branches at the University of Oklahoma and the Oklahoma A. & M. College was held at the latter school on May 18, 1931. During the morning program students of the two schools presented the following technical papers:

Choice of Petroleum Pump Station Equipment, by V. J. Sittel, Oklahoma A. & M College.

Factors Determining the Rating of Underground Cables, by Wm. M. Achgill, A. B. Bartow, T. A. Bloss, University of Oklahoma (presented by Wm. M. Achgill).

Grounds and Methods of Testing Them, by Hubert I. Short, Oklahoma A. & M. College.

System Solution by the Method of Symmetrical Components, by R. J. Thompson, University of Oklahoma.

Thyratron Tube and Its Recent Applications, by W. E. Nichols, Oklahoma A. & M. College.

Radio Field Intensity Survey, by G. S. Hammonds, University of Oklahoma.

Transmission Lines: Generator-End Requirements versus Load Constants, by P. H. Foster, Oklahoma A. & M. College.

Application of Kirchoff's Laws and Superposition of Currents in Calculating Loop and Network Circuits, by S. Alexander, University of Oklahoma.

The program was followed by a luncheon (attended by about 115) and the inspection of engineering laboratories.

At an afternoon session authors of three papers were awarded prizes as follows:

First prize ($15) S. Alexander, University of Oklahoma

Second prize ($10) Waldo E. Nichols, Oklahoma A. & M. College

Third prize ($5) Hubert I. Short, Oklahoma A. & M. College

Mr. Alexander, winner of first prize, recently has won a Tau Beta Pi scholarship for $750 and a $500 tuition scholarship from the Massachusetts Institute of Technology. In his freshman year he received a $1,000 prize offered for the best paper by the American Chemical Society.

The following names of officers of the Oklahoma City Section for next year were announced: C. T. Almquist (A'28) associate professor of electrical engineering, University of Oklahoma, chairman; A. Naeter (M'30) head electrical engineering department, Oklahoma A. & M. College, vice-chairman; and C. E. Bathe (A'29), superintendent of radio and standards, Oklahoma Gas & Electric Co., secretary-treasurer.

Section and Branch Join in Meeting at Cincinnati

The annual joint meeting of the Cincinnati Section and the University of Cincinnati Branch was held at the university on May 14, with an attendance of 80; the preceding dinner was attended by 38.

The following program was presented by seniors in electrical engineering:

Choke-Coil Design, by D. T. Michael.

Study of a Spot Welder, by F. F. Osterholz.

Study of a 500-Cycle Generator, by G. H. Pettibone.

Experimental Study of Means of Lessening Static in Receiving Sets, by G. F. Platts.

Speed Control of a D-C. Motor, by R. M. Seitz.

Pitting in Telephone Relay Contacts, by Henry Suter.

Baltimore Section Awards Prizes

Each alternate year the Baltimore Section has a prize paper meeting. For the contest this year six papers were submitted for three of which the following prizes were awarded at this meeting:

First prize: ($25)—W. P. Taylor, Consolidated Gas Electric Light and Power Company. Locating Power Cable Faults by Means of a Constant Current Transformer with Short Circuiting Switch.

Second prize: ($15)—L. J. Berherich, graduate student, Johns Hopkins University, A Method for Measuring the Phase Angles of Shielded Resistors.

Third prize: ($10)—G. M. L. Sommerman, graduate student, Johns Hopkins University, The Spark Discharge in Air.

The speakers were invited to an executive dinner preceding the regular meeting. The following officers were elected for the year 1931-32; chairman K. A. Hawley (M'12) chief engineer Locke Insulator Corporation; vice-chairman L. G. Smith (M'25) assistant to general superintendent, Consolidated Gas Electric Light & Power Corporation; secretary-treasurer J. Wells (A'27) development manager Western Electric Company.

Faraday Discoveries Celebrated at Lehigh University

In honor of the centennial of Faraday's discovery of electromagnetic induction, engineering students at Lehigh University, Bethlehem, Pa., under the leadership of the local student Branch of the Institute, held a special joint meeting April 29, 1931. Members of the several engineering societies at Lehigh presented papers descriptive of different phases of Faraday's scientific work and staged apparatus demonstrations designed to commemorate Faraday's more important discoveries.

Eight students cooperated in the preparation and presentation of five papers as follows:

1. FARADAY THE MAN, by F. W. Matchett, M. E. '31.
2. CONTRIBUTION TO CHEMISTRY, by R. C. Smith, Chem. '31 and L. S. Millelot, Chem. '31.
3. CONTRIBUTION TO METALLURGY, by W. H. Wagner, Met. E. '31 and J. S. Harrison, Met. E. '31.
4. ELECTROMAGNETIC INDUCTION, by R. E. Snyder, E. E. '31 and L. R. Wanner, E. E. '31.
5. OPTICS, by D. L. MacAdam, Engg. Physics '32.

Past Section Meetings

Akron

SOME ENGINEERING FEATURES IN CONNECTION WITH HEAVY CONSTRUCTION, by W. S. Lee, president, A. I. E. E. Illustrated by several reels of motion pictures. Dinner meeting. Election of officers for 1931-32: R. R. Krammes, chairman; R. A. Hudson, secretary; P. C. Smith, treasurer. May 22. Attendance 50.

Boston

Annual meeting and election of following officers: C. A. Corney, chairman; F. D. Hallock, vice-chairman; G. J. Crowdes, secretary-treasurer. Motion pictures and other entertainment remainder of the evening. May 14. Attendance 121.

Cincinnati

W. Weftendorp, General Electric Company, spoke on the study of the light penetration and its detection through fog. A representative of the Army Air Corps of Dayton outlined Army preparedness plans with particular reference to obtaining materials and construction for airplanes. Dinner preceded the meeting. May 5. Attendance 250.

Annual golf tournament and dinner preceded the evening meeting at which Prof. F. H. Bird, University of Cincinnati, spoke on ECONOMIC PHASES OF CITY DEVELOPMENT. Election of officers: E. S Fields, chairman; J. A. Noertker, secretary-treasurer. June 4. Attendance 46.

Connecticut

Annual outing and dinner dance. May 23. Attendance 115.

Dallas

LEAD STORAGE BATTERIES AND THE FUNDAMENTAL PRINCIPLES OF BATTERY OPERATION AND MAINTENANCE, by W. E. Dunn, Electric Storage Battery Company. Election of officers: Gibbs A. Dyer, chairman; S. M. Sharp, secretary-treasurer. May 25. Attendance 104.

Denver

Business meeting. May 12. Attendance 17.

Detroit-Ann Arbor

THE ELECTRICAL INDUSTRY AND ELECTRICAL ENGINEERING IN SOVIET RUSSIA, by A. Dovjikov, Westinghouse Elec. & Mfg. Company. Prior to this talk many members inspected the Moore's Park station of the City of Lansing. May 19. Attendance 200.

Erie

VACUUM TUBES, by A. W. Hull, General Electric Company. Election of officers: P. R. Urich, chairman; C. V. Roberts, secretary. May 19. Attendance 83.

Houston

STORAGE BATTERIES, by W. E. Dunn, Electric Storage Battery Company. J. S. Waters elected secretary. May 26. Attendance 15.

Indianapolis-Lafayette

VACUUM-TUBE CONTROL, by S. D. Fendley, General Electric Company. May 15. Attendance 94.

Iowa

RAILROAD ELECTRIFICATION DEVELOPMENTS IN AMERICA AND ABROAD, by F. W. Peters, General Electric Company. Joint meeting with the Des Moines Engineers Club and the Des Moines Architects Club. Election of officers: H. B. Hoffhaus, chairman; E. W. Schilling, secretary-treasurer. May 14. Attendance 90.

Ithaca

Election of officers: W. E. Meserve, chairman; B. K. Northrop, secretary-treasurer. Dinner meeting. May 29. Attendance 13.

Lehigh Valley

Annual meeting and exhibition at which applications of the photoelectric cell, metering equipment, and other recent electrical developments were displayed by various manufacturers. Preceding dinner the following motion pictures were shown: "Dynamic America," "The Romance of Power," "Deion Oil Circuit Breakers." Reports from the chairmen of the local committees were read and officers for the year 1931-32 were announced. PLANNING TO AVOID DEPRESSIONS, by E. C. Stone, vice-president A. I. E. E. District No. 2, was presented by R. L. Kirk, Duquesne Light Company. May 16. Attendance 135.

Los Angeles

Two papers concerning the R. C. A. 50-kw. broadcasting transmitter being installed for KFI, were presented by J. J. Farrell and G. W. Fyler, both of the General Electric Company. Election of officers as follows: P. S. Biegler, chairman; F. E. Dellinger, secretary. Joint meeting with the Institute of Radio Engineers. May 19. Attendance 203.

Louisville

Annual meeting. Reports of local committees were read, and election of officers was made as follows: Philip P. Ash, chairman; C. M. Ewing, secretary-treasurer. Dinner and entertainment followed. June 4. Attendance 37.

Memphis

POWER PLANT GENERATION AND UTILIZATION, by Robert Bruce, Memphis Power and Light Company;

THE NEW 110-KV. RIVER CROSSING, by M. Eldredge, Memphis Power & Light Company, and chairman, Memphis Section. May 12. Attendance 42.

FUSELESS HOME, by H. G. Nichols, Westinghouse Elec. & Mfg. Company. June 9. Attendance 36.

Milwaukee

Inspection trip through the Globe-Union Mfg. Company plant, and talk by W. R. Vicarey of that company on

College, Mount Vernon, Iowa. Until 1887 his time was occupied chiefly with a civil engineering practise. For the next ten years he acted as engineer for the contractor on several of the power and lighting projects of the Pacific Coast. Prior to his arrival in Tacoma (1923) Mr. Stannard had been identified with many irrigation, water works, and power plant developments along the Pacific Coast; the Grant Smith Company project in California, the Cedar River plant at Seattle, and the Bull Run plant at Portland. From 1912 to 1919 he was consulting engineer for the North Coast Power Company in Portland. At the time of his death he was serving his second term as president of the Tacoma Section of the American Society of Civil Engineers, which he had been instrumental in establishing.

William F. Callahan (A'23) engineering assistant, Western Union Telegraph Company, New York, N. Y., died May 31, 1931, at the age of forty. After the completion of studies in machine design, manual training and applied electricity at Pratt Institute, his first business connection (1910) was when he joined the Western Electric Company, New York, with which he remained as machine hand and inspector until 1913; then he became draftsman of Bramhall Deane & Company, Brooklyn, N. Y. In March 1914 he engaged with the Western Union Telegraph Company, New York City, spending three years as draftsman, followed almost immediately by appointment as engineering assistant, the position he held until his death. Mr. Callahan belonged to the Institute's New York Section, in which he was active.

Local Meetings

Utah Section and Branch Meet

The Utah Section and the University of Utah Branch held their annual joint meeting for the presentation of a student program on May 18. This was the last meeting of the Section for the present administrative year.

The following papers were presented by students:

Keying of Continuous-Wave Transmitters, by M. R. Johnson and L. K. Irvine.

Illumination of the University Campus, by L. D. Schroder and J. O. Carlston.

Stroboscopic Effects with Neon Glow Tubes, by Courtney Campbell.

Investigation of the Acoustics of Kingsbury Hall, by Fred Lundberg and F. M. Neal.

Oklahoma City Section Meets with Branches

The annual joint meeting of the Oklahoma City Section and the student Branches at the University of Oklahoma and the Oklahoma A. & M. College was held at the latter school on May 18, 1931. During the morning program students of the two schools presented the following technical papers:

Choice of Petroleum Pump Station Equipment, by V. J. Sittel, Oklahoma A. & M College.

Factors Determining the Rating of Underground Cables, by Wm. M. Achgill, A. B. Bartow, T. A. Bloss, University of Oklahoma (presented by Wm. M. Achgill).

Grounds and Methods of Testing Them, by Hubert I. Short, Oklahoma A. & M. College.

System Solution by the Method of Symmetrical Components, by R. J. Thompson, University of Oklahoma.

Thyratron Tube and Its Recent Applications, by W. E. Nichols, Oklahoma A. & M. College.

Radio Field Intensity Survey, by G. S. Hammonds, University of Oklahoma.

Transmission Lines: Generator-End Requirements versus Load Constants, by P. H. Foster, Oklahoma A. & M. College.

Application of Kirchoff's Laws and Superposition of Currents in Calculating Loop and Network Circuits, by S. Alexander, University of Oklahoma.

The program was followed by a luncheon (attended by about 115) and the inspection of engineering laboratories.

At an afternoon session authors of three papers were awarded prizes as follows:

First prize ($15) S. Alexander, University of Oklahoma

Second prize ($10) Waldo E. Nichols, Oklahoma A. & M. College

Third prize ($5) Hubert I. Short, Oklahoma A. & M. College

Mr. Alexander, winner of first prize, recently has won a Tau Beta Pi scholarship for $750 and a $500 tuition scholarship from the Massachusetts Institute of Technology. In his freshman year he received a $1,000 prize offered for the best paper by the American Chemical Society.

The following names of officers of the Oklahoma City Section for next year were announced: C. T. Almquist (A'28) associate professor of electrical engineering, University of Oklahoma, chairman; A. Naeter (M'30) head electrical engineering department, Oklahoma A. & M. College, vice-chairman; and C. E. Bathe (A'29), superintendent of radio and standards, Oklahoma Gas & Electric Co., secretary-treasurer.

Section and Branch Join in Meeting at Cincinnati

The annual joint meeting of the Cincinnati Section and the University of Cincinnati Branch was held at the university on May 14, with an attendance of 80; the preceding dinner was attended by 38.

The following program was presented by seniors in electrical engineering:

Choke-Coil Design, by D. T. Michael.

Study of a Spot Welder, by F. F. Osterholz.

Study of a 500-Cycle Generator, by G. H. Pettibone.

Experimental Study of Means of Lessening Static in Receiving Sets, by G. F. Platts.

Speed Control of a D-C. Motor, by R. M. Seitz.

Pitting in Telephone Relay Contacts, by Henry Suter.

Baltimore Section Awards Prizes

Each alternate year the Baltimore Section has a prize paper meeting. For the contest this year six papers were submitted for three of which the following prizes were awarded at this meeting:

First prize: ($25)—W. P. Taylor, Consolidated Gas Electric Light and Power Company. Locating Power Cable Faults by Means of a Constant Current Transformer with Short Circuiting Switch.

Second prize: ($15)—L. J. Berherich, graduate student, Johns Hopkins University, A Method for Measuring the Phase Angles of Shielded Resistors.

Third prize: ($10)—G. M. L. Sommerman, graduate student, Johns Hopkins University, The Spark Discharge in Air.

Pre-Faraday Developments, by I. Olcovich;

Typical Faraday Experiments, by A. Gessell;

Later Developments, by E. R. Gaerttner. After these talks the laboratories were open for inspection. May 22. Attendance 60.

Election of officers: L. C. Grussler; E. R. Gaerttner, vice-president; Irwin Olcovich, secretary-treasurer. May 26. Attendance 15.

Film—"Turbine with Solid Rotor." June 2. Attendance 16.

University of Detroit

Fourth annual banquet held at the Cadillac Athletic Club. Election of officers: Bernard Sharkey, chairman; P. Zoufal, vice-chairman; John Schenk, secretary; Thomas M. Ward, treasurer. June 3. Attendance 60.

University of Florida

Measurement of Ground Resistances, by A. W. Harris, student. May 13. Attendance 25.

Harvard University

The Queenston-Chippawa Power-Development, by R. Bullwinkle, student;

Public Utilities, by Eric A. Walker, student;

The A. I. E. E. North Eastern District Meeting at Rochester, by J. H. Wright, student. Election of officers: Eric A. Walker, chairman; Robert D. Hickok, Jr., vice-chairman; Charles N. Mason, secretary-treasurer. May 19. Attendance 14.

Inspection trip to the toll exchange of the New England Telephone and Telegraph Company, Boston. May 21. Attendance 10.

Iowa State College

Election of officers: W. L. Huebner, president; W. Hardman, vice-president; G. Franks, secretary; M. Cain, treasurer. May 22. Attendance 21.

Kansas State College

Election of officers: G. E. Cain, president; D. E. West, secretary. May 14. Attendance 100.

Lehigh University

The History of the Electrical Industry, by J. M. Bisbee, student;

Developments in the Electrical Field in 1930, by J. F. Miller, student;

Solution of Lightning Problems, by J. B. Sponsler, student. Election of officers: L. F. Underwood, president; J. D. Brown, vice-president; J. J. Grinevich, treasurer; C. W. Banks, secretary. May 13. Attendance 40.

Lewis Institute

Business meeting. Prof. F. A. Rogers nominated for counselor. May 1. Attendance 15.

Inspection trip to the plant department of the American Tel. & Tel. Company. June 3. Attendance 17.

How I Got into Engineering, by A. B. Smith, Automatic Electric Company. June 5. Attendance 68.

Michigan State College

Illustrated talk given by F. Harbin, student, featuring a film entitled "Radio Communication on Trains." May 12. Attendance 23.

Several talks by students and a demonstration of the "Telemat." Joint meeting with the University of Michigan Branch. May 28. Attendance 32.

To Find the Maximum Span of a Catenary if the Density, Tensile Strength, and Gravity Remain Constant, by L. Switzgable, student;

Discussion of the Effect of Division of Load upon Rotary Converter Systems, by G. T. Hittle, student. Explanation of the recording interferometer given by Prof. C. W. Chamberlain. June 9. Attendance 29.

University of Michigan

Business discussion. May 13. Attendance 16.

Annual banquet at which the following program was presented:

Joseph Henry, by L. C. Poole, student;

A Russian Meets a Turk, by P. D. Kalachov, student;

Michael Faraday, by L. Zanoff, student;

The Hand is Quicker than the Eye, by Prof. A. D. Moore;

Before the Drought, by Dean Emeritus M. E. Cooley. May 26. Attendance 60.

School of Engineering of Milwaukee

Life of Steinmetz, by J. D. Ball, vice-president of the school. May 13.

University of Minnesota

Tenth biennial electrical engineers' party. April 17-18. Attendance 4,100.

Banquet meeting. Election of officers: Martin G. Swanson, chairman; Harold L. Ericson, vice-chairman; Scott McDermott, secretary-treasurer. May 19. Attendance 33.

Mississippi A. & M. College

Election of officers: J. M. Caldwell, chairman; C. R. Lillybridge, vice-chairman. May 20. Attendance 27.

University of Missouri

The Possibilities in Engineering, by R. V. Wright, president of A. S. M. E. Joint meeting with the A. S. M. E., A. S. C. E., and A. I. Ch. E. April 30. Attendance 43.

Audible Light, by J. B. Taylor, General Electric Company. May 18. Attendance 176.

Montana State College

Transformer Design, by R. Bjork, student;

Volta Power Plant, by N. Hovey, student;

Black Eagle Plant, by T. Micka, student. May 14. Attendance 99.

The Electrical Show at Washington State College, by W. Rightmire, student;

The Impedance Bridge, by P. O. Koetitz, student;

Office Illumination, by R. Rydell, student. May 21. Attendance 94.

University of Nebraska

The Lincoln Telephone & Telegraph Company's first aid team gave a demonstration covering the high points of first aid work. May 13. Attendance 45.

University of Nevada

Election of officers as follows: Donald Knapp, chairman; Calvin Dodson, vice-chairman; Orvis Reil, secretary-treasurer. May 3. Attendance 21.

University of New Hampshire

Moving pictures and talks by E. J. Shaw and L. M. Shampeau, both of the Westinghouse Elec. & Mfg. Company. May 6. Attendance 56.

Talk by W. S. Keay, New England Gas & Electric Association. May 20. Attendance 80.

Business meeting. May 27. Attendance 16.

University of New Mexico

Smoker. Economics of Neon Lighting, by E. Huffman and H. Mendenhall, students. H. Bangerter and S. Pelatowski, students, gave a demonstration of some of the effects of ultra-short radio waves. May 28. Attendance 21.

College of the City of New York

Transmission of Power, and High-Voltage Insulators, by Mr. Wildebrandt, Ohio Insulator Company. May 21. Attendance 15.

University of North Carolina

Engineering in the Latin Countries, by Professor Bennett. May 14. Attendance 23.

North Dakota State College

Radio Broadcasting, by D. F. Holaday, student;

Magnetism, by B. Weiss, student;

Michael Faraday, by E. Blomquist, student;

Some Actual Experiences, by R. Stockstad, student;

Life After Graduation, by Professor H. Rush, counselor;

Relations of Industry to College Men, by J. D. Taylor, Northwestern

Bell Telephone Co. May 27. Attendance 15.

University of North Dakota

Photoelectric Cells and Applications, by Eugene Becken, student;

The Institute and Its Functions, by Prof. H. F. Rice, counselor. May 13. Attendance 28.

University of Notre Dame

Annual picnic. May 16. Attendance 160.

The Marvels of Sound Transmission, by S. P. Grace, assistant vice-president, Bell Telephone Laboratories, Inc. May 19. Attendance 1,300.

Ohio Northern University

Banquet meeting. Electrical Engineers in Industry, by Prof. A. D. Moore. Election of officers: O. R. Jacobs, president; B. Wyant, vice-president; W. Gideon, secretary; O. Hawes, treasurer. May 29. Attendance 75.

Ohio State University

Demonstrations were performed by the students using the new equipment just acquired for the electrical engineering department. May 1. Attendance 60.

Ohio University

The Large Differences Which Are Made by the Little Differences in Men, by Dr. E. B. Bryan, president of the University. Election of officers: George Wyckoff, chairman; William Miller, vice-chairman; William Cooper, secretary-treasurer. May 6. Attendance 41.

Oregon State College

Submarine Cables, by E. D. Pearson, North Western Electric Company. S. B. Clark, of the same company, supplemented this talk by describing the manufacture of submarine cables. Election of officers: Dale Hansen, president; Elliott MacCracken, vice-president; George Howie, secretary; Stewart Kibbe, treasurer. May 12. Attendance 71.

Pennsylvania State College

Report of Oscillographic Studies of the Sources of Commutator Ripples in D-C. Machinery with Particular Reference to the Rotary Converters, by Messrs. Conrad, Forster, Foster, and Pollock, students;

Report of Capacitor Induction Motor Studies, by Messrs. Henderson, Kennedy, Lauth, and Sauter; students;

Demonstration of the Stroboscopic Possibilities of the Neon Lamp, by W. W. Harris, student.

Illustrated lecture on Alaskan Salmon Fisheries, by Prof. B. L. Robertson. May 18. Attendance 40.

Purdue University

Two films shown—"Voices Across the Sea" and "By-Products of a Telephone Research Laboratory." Election of officers: P. O. Peterson, president; M. W. Brown, vice-president; E. M. Sharer, secretary; G. K. Miller, treasurer. May 15. Attendance 30.

Rhode Island State College

Business meeting. May 27. Attendance 6.

Rice Institute

Election of officers: M. E. Kattmann, chairman; H. A. Martin, vice-chairman; E. A. Turner, Jr., secretary; R. C. Bearmann, treasurer. May 13. Attendance 20.

University of South Carolina

Alexander Graham Bell, by W. O. Farnam, student;

Sound with Pictures, by R. L. Phillips, student;

Silver Selenide with a Secret Metal Used by a German to Get Electricity from Solar Rays, by J. T. Sanders, student;

The X-Ray—New Watch-Dog of Safety, by J. B. Dent, student. May 18. Attendance 31.

Annual banquet. May 16. Attendance 16.

Thomas Alva Edison, by W. E. Crum, student;

The Variable Mu Tetrode, by J. W. Palmer, student;

A South Carolinian—W. S. Lee, by C. D. Caughman, student. May 11. Attendance 29.

University of Southern California

Recent Developments in the Electrical Industry, by W. F. Grimes, Westinghouse Elec. & Mfg. Company. April 22. Attendance 23.

Chain Broadcasting, by Paul Johnson, Pacific Tel. & Tel. Co. April 29. Attendance 26.

Application of Electricity in the Oil Fields, by C. J. Ruzicka, Standard Oil Company. May 6. Attendance 26.

Layout of Substations on the 220-Kv. Distribution System of the Edison Company, by J. M. Gaylord, Southern California Edison Company, Ltd. May 13. Attendance 26.

H. M. Cox, Bureau of Power & Light, gave instructions on artificial respiration and some useful hints on first aid, with special reference to burns which might be received by an electric current. Election of officers: M. C. Marshall, chairman; John Ganzenhuber, vice-chairman; Louis Bayha, secretary; Oliver Jessen, treasurer. May 20. Attendance 28.

Development of the U. S. Motors Corporation, by W. M. Hogne, of that company. May 27. Attendance 31.

Stanford University

Life and Work of Michael Faraday, by G. W. Dunlap, student;

Experiences at the General Electric Test Course. by M. Born, student. May 19. Attendance 12.

Residual Currents and Voltages in Electrical Power Systems, by G. H. Kimball and C. A. Bairos, students. June 2. Attendance 10.

Election of officers: Madison R. Jones, Jr., chairman; G. W. Dunlap, vice-chairman; Ronald H. Born, secretary-treasurer. June 5.

University of Tennessee

Mercury Vapor Lamps, by H. DuBose, student. Election of officers: H. M. Patterson, chairman; G. L. Dyer, vice-chairman; C. T. Nunley, secretary-treasurer. May 5. Attendance 13.

University of Texas

Research and Industry, by E. L. Manning, General Electric Company. Joint meeting with the A. S. M. E. and A. S. C. E. April 22. Attendance 60.

Theory and Applications of Electric Relays, by H. P. Robinson, Houston Power & Light Company. May 15. Attendance 23.

Virginia Polytechnic Institute

Election of officers: R. E. McDaniel, chairman; M. W. Bowery, vice-chairman. May 29. Attendance 20.

West Virginia University

Light Beams to Operate Traffic Signals, by C. E. Higgins, student;

The Du Pont Ammonia Plant at Charleston, W. Va., by H. A. Lewis, student;

Safety at Night for the Aviator, by V. S. Monteith, student;

Your Nimble Servant—The Electron, by P. J. Johnson, student. May 5. Attendance 15.

Washington State College

The Vacuum-Tube Voltmeter, by Mr. Emigh, student;

Short Circuits on Main Transmission Lines, by Mr. Holmes, student. May 8. Attendance 13.

Washington University

General discussion. May 14. Attendance 18.

University of Wisconsin

Film—"Electrical Measuring Instruments." April 28. Attendance 40.

Business meeting. May 26. Attendance 20.

Employment Notes

Of the Engineering Societies Employment Service

Men Available

ENGINEER, E. E. degree, age 30, married. Wide experience in layout, design, and research of small electrical parts, radio, motion picture and sound system apparatus. Desires position in laboratory or drafting room. A-1 references. Available immediately. Location, New York. B-5138.

GRADUATE MECHANICAL-ELECTRICAL ENGINEER, married. Nine years in public utility, testing, substation construction. One year with consulting engineer. Eight years electrical engineer, central department for group of large industrial plants; layout, operation, power distribution, economy. Three years electrical, process engineer, manufacturing plant; development, efficiency, supervision. Excellent references. East preferred. Available short notice. C-9312.

DEVELOPMENT AND RESEARCH ENGINEER, B. S. in E. E., M. S. in physics, 34, married. Four years' experience in one of largest research laboratories in electromagnetic problems and measuring instruments, knowledge of radio-frequency circuits and vacuum tubes, have patents granted, high designing and supervising skill. Desires position with future. C-9333.

CHIEF ELECTRICIAN AND MANUFACTURING ENGINEERING ASSISTANT, technical graduate, 34. Fourteen years' experience covering electrical installation, operation, and maintenance, and the manufacturing of mechanical and electrical parts. Desires position as plant electrician, testing of electrical machinery or apparatus, or engineering assistant. Moderate salary to start. Location, Northern New Jersey or vicinity. C-9305.

GRADUATE ELECTRICAL ENGINEER of Purdue University with eighteen years' experience in design, construction, estimating, costs, valuation and appraisal of power plants, substations, transmission lines and industrial plants including five years in heavy electric traction and rapid transit work. Open for opportunity with future. C-8256.

ELECTRICAL ENGINEER, 1930 graduate, 22, single. One year on the Westinghouse Student Course. Desires position as instructor in electrical engineering. Available school year 1931-1932. References. Location, immaterial. C-9311.

ELECTRICAL CONSTRUCTION ENGINEER, age 45; 25 years' experience. Has a broad technical knowledge, and extensive practical experience in commercial and industrial power and lighting construction including underground, power house and substation installations and railway electrification work. Has a thorough knowledge of estimating and valuation work and the supervising of construction forces. C-1140.

ELECTRICAL ENGINEER, 27, single, graduate of German college, six years' experience in design, research, and test on magnets, fractional horsepower motors, and control systems for mine hoists and elevators with leading American and German concerns. Desires position where knowledge of theoretical and practical is of importance. C-9810.

ELECTRICAL AND ILLUMINATING ENGINEER, 42 years old, 23 years' experience, electrician, superintendent, estimator, engineer, instructor. Power station, commercial and industrial building wiring, etc. Seven years in engineering for architects, office buildings, theaters, hotels, schools, hospitals, industrial buildings. Would like engineering position, or sales engineering. C-8460.

ELECTRICAL ENGINEER, graduate, E. E. degree, 28, married. Three years' experience relays, relay studies of large electric power and light utility, operating, New York City. Three years testing, design, and development work on new electrical appliances and materials. Experience includes considerable outside contact with leading electrical manufacturers. Available immediately. Location, New York City. B-8793.

ELECTRICAL ENGINEER, American. Street railway, main-line electrification, mining, and public utilities. Twenty years in Latin America as engineer and manager. Did considerable Diesel-engine and refrigeration work. B-5912.

ELECTRICAL ENGINEER, graduate Georgia Technology, 1930, cooperative plan. Westinghouse lighting courses. Cooperative work, alternate months, five years in substation maintenance and office engineering. Rebuilding transformers, switches, lightning arresters, work with electric furnaces, rectifiers, meters, motors, etc. Checking and mapping distribution systems, work orders, drafting, etc. Excellent references. Perfect health. Location immaterial. C-7847.

EXPERIENCED ELECTRICAL ENGINEER, graduate of two colleges, with twenty years of accomplishment in the electrical wire and cable industry; American, Protestant, and in good health. Would prefer to locate within 100 mi. of New York, though not essential. Can come for interview promptly; all references desired. B-9877.

MECHANICAL-ELECTRICAL ENGINEER, 46, single, 23 years' experience. Factory test, central station engineering, and sales work. Public utility operating engineer, assistant superintendent, and superintendent of construction, power and electric departments. Estimate and design work on substations, stations, relay systems, and lines. Specifications for buildings. B-271.

ELECTRICAL ENGINEER, 48, college graduate, married; 26 years' experience as designing, report, power and executive engineer with three engineering and construction firms, including system planning, design, construction cost estimating and construction supervision of power plants, substations and transmission facilities for public utilities and industrials. Studies of operating economics. B-4558.

ELECTRICAL ENGINEER, 26, single. Three years' experience with construction company, specializing in new construction. One and a half years' experience in light current work with leading telegraph company. Desires connection with company in construction or sales engineering departments. Location, New York City preferred. C-9290.

EXECUTIVE ELECTRICAL ENGINEER, 29, married. Six years' experience in design, and construction of transmission lines and substations. Now district manager for electrical manufacturing concern. Desires to make change. Available immediately. Location, immaterial. C-9324-315-C-4-San Francisco.

COLLEGE TRAINED ENGINEER, 29, married. Experienced in the design and estimating of distribution systems. Nine years' utility experience in responsible position. One and a half years' power cable engineering. Desires position with New York City utility, engineering or industrial company. Excellent references. C-9361.

HEAD OF ENGINEERING DRAWING DEPARTMENT of prominent university for seven years, will consider change to similar position. Available June 1931. B. S. in electrical engineering. Telephone and electrical experience. Practical machine designer. B-8248.

ELECTRICAL ENGINEER, graduate of University of Illinois, 1926. Two years' experience with Westinghouse, and two and a half years with public utility in planning division. Available immediately. C-9381.

GRADUATE ELECTRICAL ENGINEER, 29, married. One year eight months, Westinghouse test. Two and a half years' electrical construction with utility, engineering, supervision and reports. One year three months with consulting engineers. Desires position in planning department of public utility. No preference in location. C-7695.

ENGINEER, age 27, B. S. three years and seven months C. E. experience, desires position with hydroelectric project. Qualified for chief of party, transitman, estimator, assistant engineer. C-9382.

GRADUATE ENGINEER, age 35, two years' shop experience, fourteen years as draftsman in design of mechanical and electrical apparatus. Graduate of mechanical and electrical engineering courses of International Correspondence Schools. Willing to accept drafting or engineering position anywhere. C-9387.

EXECUTIVE OR STAFF ASSISTANT, engineering education. Fourteen years' broad experience with manufacturing, utility, and industrial surveys covering cost reduction, production planning, standards, wage incentives, scientific management methods, statistical control systems, expense and cost analysis. Capable organizer. Profitable assistant for busy executive. Prefers East. Consider any proposition. B-9122.

COMMUNICATION ENGINEER, 31, single. Experienced: telephone, radio installations; design, development of testing equipment for telephone, radio, sound-picture circuits; design, use of semi- and full-automatic testing circuits to eliminate human element in testing; industrial applications of photoelectric cells, thermionic tubes. Best references as to professional ability, personal integrity. Location, immaterial. Available immediately. C-9376.

ELECTRICAL ENGINEER, age 29, married, Pennsylvania State graduate 1925, with four years' railroad and subway signal installation experience as engineer, draftsman, and signalman, and one and a half years as assistant project engineer on railroad electrification; desires position in either of these lines. Location, anywhere. C-5089.

A-C. DESIGN ENGINEER, induction, and synchronous motors above 20 hp., alternators and auto-transformers. Experienced in the application of synchronous motors to compressor drive. Married. Location, immaterial C-9386.

PHYSICIST, middle-aged, experienced in industrial research, supervision of research, executive work, and teaching physics for engineering and other classes of students. Advanced degrees in physics from prominent American universities. Emphasis of electrical subjects in training and teaching. Stability and opportunity desired. Available on short notice. C-7900.

ELECTRICAL ENGINEER, EXECUTIVE, FOREMAN, 25 years' sound practical, technical, electrical and mechanical manufacturing experience in telephone and telegraph apparatus, instruments, printing machines, and pressed metal. Capable organizer and supervisor. Works and office system, estimating, cost analysis and accounts. Methods, tool design, machine and press-work, time-study rate-setting, moderate salary. Any location. C-3241.

DESIGN ENGINEER, twenty years' experience in design of a-c. machines covering polyphase induction motors of all sizes. Single-phase induction motors with inductance or capacity starting. Single-phase commutator motors of series, repulsion, and repulsion-induction type. Desires design or development work. Location, immaterial. C-8540.

1931 GRADUATE ELECTRICAL ENGINEER, B. E. E. University of Minnesota. Single, age 22. Special courses taken include design, radio and telephone. Desires position with any manufacturing or engineering firm. Location immaterial, opportunities and experience being main factors. Available immediately. C-9391.

INDUSTRIAL PRODUCTION MAN, electrical engineer, married, age 29, good health, graduated 1924, seven years' experience with large construction company on design, engineering, and construction of power and industrial plants. Wants production department job where electrical training and experience will count, with possibility of working into management. Location, New England. C-9384.

ELECTRICAL OR MAINTENANCE ENGINEER, 48, married, college graduate, 22½ years with present employer. Plant sold to large organization with its own engineers. Unusual experience in installation and operation of industrial substations, large synchronous motors, replacing 25 with 60 cycles and maintenance. Good mechanical, steam and process development experience. C-9399.

ELECTRICAL ENGINEER, B. S. degree, married, with about fifteen years' successful experience in the design and construction of transmission and distribution lines. Some teaching experience. Employed at present. Desires position as instructor in electrical engineering subjects or physics and mathematics. Excellent references. Location preferred, Middle West or West. C-9339.

ELECTRICAL ENGINEER, 27, single, B. S. E. E. Six months Westinghouse Graduate Student Course. Two years' laboratory work circuit interrupters, large power rectifiers, one and a half years' development work on standard magnetic controllers for steel mill applications, handling negotiations, estimating on motor-control apparatus. Familiar French language. Available immediately. Location, preferably East. C-9393.

ELECTRICAL ENGINEER, 36, single, citizen, desires position with engineering, manufacturing, or public utility concern. Six and a half years' experience in power plant and substation design. Two years in electrical furnace work. Highest education. Additional G. E. engineering course. Speaks foreign languages. Available on short notice. C-2710.

1929 ELECTRICAL DESIGN ENGINEER, 24, B. S. degree technical school. One year Westinghouse Student Course. Motor, transformer, turbo test experience. One year large synchronous motor design. Six months Westinghouse electrical design school. Desires position, design, research, development work with manufacturing company, or engineering department power company. Single with dependents. Location, immaterial. References. Available immediately. C-9410.

GRADUATE ELECTRICAL ENGINEER, Lehigh University (1930), married, 25, ten months engineering graduate student at Westinghouse, 22 summer months with National Tube Company. Desires position with public utility or manufacturing company where analytical and research ability is prime prerequisite. Available on two weeks' notice. Location, East or Middle West. C-9395.

1931 ELECTRICAL GRADUATE, midwest university, 22, single. Tau Beta Pi student. Desires connection with manufacturing or public utility concern. Location preferred, Middle West. C-9398.

ELECTRICAL ENGINEER, graduate Georgia Technology, 1930, age 23, married, now employed by large industrial corporation. Desires position with public utilities or with small industrial, United States or foreign. Available on short notice. C-9396.

ELECTRICAL ENGINEER, 31, married, college graduate, with six and a half years' experience consisting of: oil circuit breaker design; electrification of industrial plants; operation, maintenance and electrification of ore mines and steel mills. Thoroughly experienced on motor applications, transformer stations, switchboards, and distribution systems. Last one and a half years as electrical engineer with steel company. C-9414.

ELECTRICAL ENGINEER, 30, married, A. B. '22, B. S. in E. E. '24 (Harvard). G. E. Test, transformer design, development and technical writing; experience in factory planning, has taught evening classes; speaks German. Location preferred, East. C-9402.

ELECTRICAL ENGINEER, draftsman, experienced designer of light and power layouts of generating substations (indoor and outdoor) office buildings, factories and air ports. Technical school graduate and fifteen years' practical experience in the electrical and mechanical industry. C-7979.

REPRESENTATIVE available. Experienced sales engineer, electrical engineer, graduate. Desires high-grade electrical line of utility or heavy-duty industrial equipment. Eastern location. B-4067.

ELECTRICAL ENGINEER, 36, university graduate, married. Twelve years with large public utility as cadet, inspector and electrical tester (motors, transformers, cables, and electrical appliances). Also one and a half years' research on combustion control apparatus for instrument manufacturer and some engineering sales experience. Desires position with future near Philadelphia. References. C-8350.

ELECTRICAL ENGINEER, 1928 graduate of a recognized university, 26, single. One year central station testing, twenty months special apprentice on a large electrified railroad and seven months' telephone experience. Seeks engineering position where the above training and experience can be applied, free to locate anywhere. C-9112.

GRADUATE ELECTRICAL ENGINEER, S. B. from M. I. T. in 1927. Accidental injury has prevented employment. Now recovered. Has done considerable study since graduation in electrical engineering and physics, particularly radio and acoustics. Interested in most any kind of connection. Available at once. Single, age 25. C-9205.

SALES ENGINEER, distinctly electrical background, has good sales record, profit-minded, 39, single, likes people and contacts. Seeks permanent connection with leading company manufacturing controls for industrial applications. Conversant with thermoelectric and photoelectric principles. Specialized knowledge of conductors. Decided interest in distribution in broadest sense. Has proved executive ability. C-8797.

TECHNICAL GRADUATE, 32, with broad experience in operation, maintenance of substations, cable network, electric shovels. Substation testing. Speaks five languages. Desires connection with responsible company. Location, immaterial. B-9611.

ELECTRICAL ENGINEER, 36, married, 18 years' experience on power plants, transmission lines, substations, switchboards. Telephones, mine electrical equipment, motors, lighting, marine electrical work, draftsman. Five years electrical engineer wiring for power, light, telephones, signal systems, elevators for all types of buildings; also expert plumber, heater and tinner. C-9348.

GRADUATE ELECTRICAL ENGINEER, married, age 27, one year Westinghouse Student Course, two years' production control; two years' maintenance engineering. Desires permanent position with future. Will consider anything. Location, immaterial. C-9425.

GRADUATE ELECTRICAL ENGINEER, 1929, 22, single; 15 months on General Electric Test Course. Desires position with utility or manufacturing company or with concern doing consulting or construction engineering. Available immediately. Location, New England preferred. C-8028.

1931 GRADUATE ENGINEER, single, age 23. B. S. in E. E. from Lafayette College. Ten months' experience as assistant engineer with large belting company. Three months radio coil test. Prefers engineering position with engineering company or manufacturing company. Best of references. Location, immaterial. Available immediately. Slight knowledge of Spanish. C-9422.

GRADUATE ELECTRICAL ENGINEER, B. E. E. degree, 1930, 24, single; eight months on Westinghouse course. Assignments covered motor apparatus testing and refrigeration development work. Desires position with manufacturing concern or public utility. Working knowledge of Spanish. Initial salary and location secondary to opportunity. Reference. Available on short notice. C-9428.

GRADUATE ELECTRICAL ENGINEER, age 28, married, with eight years' experience in industrial plant construction and maintenance; railway electrification; power-plant design, estimating, and construction. Supervisory experience on construction and costs with contractor. Desires position with utility, manufacturer, or contractor, where ability to handle labor and produce results is a prerequisite. C-4428.

RECENT GRADUATE, 23, Pratt Institute in Industrial electrical engineering. Four years' practical experience in installation work and operation of substations. Specialized in motor control. Desires position with power company or related work in manufacturing or construction. Location, immaterial. C-9176.

ELECTRICAL-MECHANICAL ENGINEER, married, seven years' experience including G. E. Test, substation, and distribution with utility, development with electrical manufacturer, superintendent of small shop and operation of substations and motor rooms with a steel mill. C-1068.

MOTOR DESIGNER, graduate electrical engineer, 33, married, experienced in design of a-c. and d-c. motors and generators. Available immediately. C-8553.

ELECTRICAL ENGINEER, 27, Italian, M. S. Harvard University, Dr. Eng. University of Rome, exceptional theoretical and research grounding, five years' experience best firms electrical communication in Italy, United States America, Germany, England. Desires position for design or research work in Europe, England or continent. C-9431.

ELECTRICAL ENGINEERING TEACHER, B. S. and M. S. in E. E., G. E. Test, eleven years' teaching experience with recognized technical school. Desires permanent position. Available September. Excellent references. Age 36. C-5807.

ELECTRICAL ENGINEER with fifteen years' experience in design, construction, reports and editorial work. Available for publicity or editorial work on trade publications. References with leading engineering and publishing firms can be furnished. B-4022.

ELECTRICAL ENGINEER, technical college graduate, age 35. Ten to twelve years' mechanical and electrical experience in power plants, substations, transmission and distribution systems. Work includes G. E. Test and public utility engineering and operation. Desires position on operating staff of power company. Location, not particular. B-9732.

GRADUATE ELECTRICAL ENGINEER, 46. Eighteen years' experience in the manufacture of electrical wiring devices, including designing, development, testing, estimating, cost and production work. Four years with underwriters' laboratories in charge of a branch office making inspections, tests, examinations, and reports. Desires position with manufacturing concern, inspection bureau or experimental laboratory. C-8449.

ELECTRICAL ENGINEER, 37, single, B. Sc. Eng. London University 1920. Six years with British Thomson-Houston Company. Two years with power company in Pennsylvania. Three years with General Electric Company. Five years war service. Available at once. Any location. C-2248.

ELECTRICAL ENGINEER, one year's experience test course. Three years' experience transmission engineering department of large eastern electrical manufacturer. Desires position with utility company, teaching. Thoroughly familiar power system short-circuit, stability analyses, theory, application of method of symmetrical components. B. S. E. E. University of California 1927, 24, married. Available July first. C-9437.

ELECTRICAL ENGINEER, B. S. in E. E., age 30, married. Manufacturing and test experience. Public utility transmission and distribution engineering experience. Sales experience. Executive and teaching ability. Salary expected, open to offer. Position desired, open to offer. Available at once. C-7867.

ELECTRICAL ENGINEER, 28, married, four years out. One year power utility course, three years telephone and talking pictures. Previous experience as commercial radio operator. Would be valuable to concern requiring capable engineer. Position must be permanent with future. Location not a guiding factor. Best of references are available. C-7902.

ELECTRICAL ENGINEER, 30, married, graduate 1924. Two years' postgraduate work, advanced electrical theory, two and a half years' writing specifications for the manufacture and installation of telephone repeater offices, one year at generator design and two years as field engineer for public utility. Desires position with future. C-951.

ELECTRICAL ENGINEER, B. S. in E. E., single, age 27. Five years' experience with electrical manufacturer on the development, design, and application of lightning arresters. Also close contact with lightning field investigations of recent years; familiar with this work and its results. Position with operating company preferred. C-9449.

TEACHER OF ELECTRICAL ENGINEERING, 37; married. Thirteen years' teaching experience; many summers spent in practical work. B. S. in E. E. and E. E. degrees. Taught all electrical engineering subjects as well as physics, electric thermodynamics, descriptive geometry, mechanical drawing. Sixteen months' general management large college radio station. Available immediately. C-9445.

ELECTRICAL ENGINEER, E. E. graduate 1924, age 29, married. One year telephone maintenance, two years General Electric Test, one year research, four years system operator large public utility. Experienced radio installation and maintenance. Desires position along line of experience with advancement opportunities. Location preferred, vicinity of greater New York. Available now. C-4182.

ELECTRICAL ENGINEER, 22, single, university graduate '31. Desires junior position in test or design departments of power machinery manufacturing concern. Experience limited. Location preferred, East. Available on short notice. C-9447.

ELECTRICAL ENGINEER, graduate 1931, single. Three years' cooperative experience in public utility maintenance work. Four summers' experience in ice-cream industry. Desires opening offering steady work and possibility of advancement. Location and type of work secondary. Available at once. C-9418.

ELECTRICAL ENGINEER, class '31, from a southern technical institute desires a part or full-time position as instructor in mathematics or electrical engineering with the privilege of carrying graduate work. C-9415.

1931 GRADUATE ELECTRICAL ENGINEER, age 26, industrious, reliable, Russian and American education seeks permanent connection. Location, immaterial. C-9455.

ELECTRICAL ENGINEER, 43, married, twenty years' electrical, power, and industrial plants experience in construction, maintenance of distribution, and transmission lines. Desires position with public utility or industrial plant. Can qualify as electrical superintendent. Used to handling men. Available on short notice. Canada preferred but would consider other location. C-9459.

ELECTRICAL ENGINEER, B. S. E. E. '30, age 22, single. One year General Electric Test. Desires position in either sales or operating department of public utility, or in any electrical line offering a future. Location, immaterial. Available at once. C-9454.

GRADUATE IN ELECTRICAL ENGINEERING, 1931, age 26, single, has B. S. in E. E. One year of electrical testing with large utility company. One year of electrical drafting of power and control switchboards. Three years' work in practical electricity. Interested in construction and supervision of small plants. Available at once. Location, anywhere. C-9457.

JUNIOR ENGINEER, 1931 graduate, B. S. E. E., University of Alabama. Desires position with utility, construction, manufacturing company. Location, immaterial. Experienced in power-plant and building installation and industrial control, having been employed for eight summer months and one full year, first as electrician helper and later as first-class electrician. C-9446.

RAILROAD ELECTRICAL ENGINEER, college graduate; A. I. E. E., A. S. M. E. A. E. R. A., A. R. A. membership; six years' design, construction, and operating experience on two large American railroad electrifications; familiar with American and European practises regarding motive power, substations, catenary, transmission lines. Excellent references; young. Desires position with consulting firm, railroad, power company, or manufacturer. C-8463.

GRADUATE in electrical engineering, class of '29, 25 and single; fourteen months G. E. Test. Four months' experience in research. Desires position in engineering department of utility or manufacturing company offering a future. Available at once. Location, eastern United States. C-9003.

ELECTRICAL ENGINEER, 32, technical graduate, twelve years' experience with public utilities; familiar with operation, design and construction of transmission lines, substations, steam and hydro-generating stations. Familiar with field and office work. Desires responsible position with holding company, operating company or consulting engineer. Location, immaterial. Available immediately. C-6401.

ELECTRICAL ENGINEER, 36, married, technically trained, fifteen years' experience covering complete engineering design, supervision of power plants, high-voltage switching stations, substations, transmission lines, including estimates, specifications, purchase of equipment, supervision of construction. Experience covers system development, investigations of systems for load conditions, expansion, relay and stability studies, frequency and load control. C-7194.

ELECTRICAL ENGINEER, E. E. from European electrotechnical university, M. S. from University of Michigan; 9 years' experience with public utilities in construction, maintenance, and design; three years with Westinghouse switchboard department, including engineering school; desires position of designing engineer with public utility or large industrial concern. C-4976.

ELECTRICAL ENGINEER, 22, single. E. E. degrees, 1929; M. S. in E. E. from M. I. T., 1931; 20 months' General Electric Test course. Desires position involving electric design and development or as instructor in electrical engineering. Location preferred, East. Available immediately. C-9462.

JUNIOR ENGINEER, 1930 graduate, B. S. degree in E. E., associate member of Sigma Xi. Eight months' practical experience in research, design, and testing with large radio concern. Desires position as engineering instructor or in any electrical line offering a future. Eastern location preferred. Salary secondary to opportunity. C-9300.

SALES ENGINEER, 36, married, graduate electrical engineer, fifteen years' experience, includes sale signal and telephone apparatus, control and charging equipment, light machinery and its design. Also field supervision, organizing, technical writing, engineering building projects, layouts, specification writing, estimating, teaching, lecturing. Available within two weeks. Location, vicinity New York City. B-247.

ELECTRICAL, STEAM, AND MECHANICAL SUPERVISOR, 33, married, twelve years' experience in industrial and power plants. For the past four years has had charge of all steam and electrical power and maintenance of large industrial plant consuming 4,000 kw. and 1,200 hp. steam. B-7004.

GRADUATE ELECTRICAL ENGINEER, 30, married. Seven years' practical experience in design and construction of substations, electric distribution both overhead and underground, with relay application, industrial power layout, lighting design, familiar with the latest developments in these lines. Available immediately. B-6384.

ELECTRICAL ENGINEER, bachelor and master degrees; fourteen years' peculiarly broad experience in test, research and development, standardization, consultation, university teaching, executive work, personnel; familiar with both power and radio equipment and practise. Stability and opportunity primary; initial salary and location secondary. Available at once. C-4591.

COLLEGE GRADUATE, 27, single, B. S. in E. E. Eighteen months General Electric Test, 22 months telephone equipment engineer. Desires position in manufacturing or utility company. Location preferred, Middle West; however, not essential. Available at once. C-9285.

Membership

Recommended for Transfer

The board of examiners, at its meeting of June 5, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

To Grade of Fellow

MOWBRAY, WILLIAM J., cons. elec. engr., Cranston, R. I.

WELLER, GEORGE L., equip. and bldgs. engr., The Chesapeake & Potomac Tel. Co., Washington, D. C.

To Grade of Member

ASHMORE, JOSEPH, dist. mgr., British Elec. Repairs, Ltd., Birmingham, Eng.

BIEGEL, EARL J., asst. supt. elec. dist., Memphis Pwr. & Lt. Co., Memphis, Tenn.

BOROKHOVICH, JOHN A., asst. engr., Brooklyn Edison Co., Brooklyn, N. Y.

CLARK, EDWIN E., asst. prof. of elec. engg., South Dakota State School of Mines, Rapid City, S. D.

EVERITT, WILLIAM L., assoc. prof. elec. engg., Ohio State University, Columbus, Ohio.

GRAHAM, ROBERT W., asst. elec. supt., Bethlehem Steel Co., Buffalo, N. Y.

GRISCOM, SAMUEL B., central sta. engr., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

HAINES, THOMAS H., supt. maint. of lines dept., Edison Elec. Illuminating Co. of Boston, Mass.

HARTMAN, HOWARD W., design engr., General Elec. Co., Schenectady, N. Y.

HELLERN, BERNHARD, production engr., National Industri, Drammen, Norway.

JONES, EVAN R., transm. engr., Mountain States Tel. & Tel. Co., Denver, Colo.

KAIGHN, HERBERT E., cons. engr., Wilmington, Del.

KLEIN, HARRY R., JR., engr., Brooklyn Edison Co., Inc., Brooklyn, N. Y.

LAKE, MARSHALL E., pwr. sales engr., Duke Power Co., Charlotte, N. C.

MIER, C. WALKER, engr., Southwestern Bell Tel. Co., Oklahoma City, Okla.

MILBURN, LOYAL B., asst. elec. engr., Great Lakes Steel Corp., Detroit, Michigan.

MOREHOUSE, ADEN K., toll service supervisor, Pacific Tel. & Tel. Co., Portland, Ore.

OVERROCKER, RANDALL H., asst. engr., New Jersey Bell Tel. Co., Newark, N. J.

PURDY, HARRY E., engg. asst., Brooklyn Edison Co., Brooklyn, N. Y.

SPOONER, HOWARD M., field engr., United Engineers and Constructors, Inc., Newark, N. J.

STEBBINS, FREDERICK O., engr., General Elec. Co., Schenectady, N. Y.

YERKES, EARLE P., engineer of equipment, Bell Telephone Co. of Pa., Philadelphia, Pa.

YOUNG, HADLEY E., supt., East Canada Creek Hydro Sta., New York Power & Light Corp., Little Falls, N. Y.

ZEBLEY, JUNE S., supervisor of inspectors, Elec. Dept., Dist. of Columbia, Washington, D. C.

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before July 31, 1931.

Balliett, C. G., Rochester Telephone Corp., Rochester, N. Y.

Balmford, J. A. (Member) Columbia University, New York, N. Y.

Barksdale, G. R. (Fellow) Tennessee Electric Power Co., Chattanooga, Tenn.

Brobson, J. F., Detroit Daily Mirror, Detroit, Michigan

Bulkley, O. R., Southern California Edison Co., Long Beach, Calif.

Clark, J. H., Southern California Telephone Co., Los Angeles, Calif.

Cline, J. E., Southern Indiana Tel. & Tel. Co., Seymour, Indiana

Eliason, W. L., Ontario Paper Co., Ltd., Thorald, Ont., Canada

Ennis, A. G., Philadelphia & Reading Coal & Iron Co., Pottsville, Pa.

Finfer, Sidney, Police Department, City of New York, New York City, New York

Finley, R. F., New York Central Lines, New York, N. Y.

Foernsler, L. O., 11113-113th St., Richmond Hill, N. Y.

Gray, L T., Jr., Pacific Gas & Electric Co., San Francisco, Calif.

Hansen, F. A. (Member) Holophane Co., Inc., Los Angeles, Calif.

Hery, V. D., Index Machinery Corporation, Cincinnati, Ohio

Karle, J. J., Kny-Scheerer Corp., Long Island City, N. Y.

King, C. J., Montaup Electric Co., Somerset, Mass.

Korik, C. (Member) Home Engineering Co., Philadelphia, Pa.

Lee, A. C. (Member) Duke Construction Company, Durham, N. C.

Long, W. F., Union Electric Light & Power Co., St. Louis, Mo.

Mallory, D. D., Valparaiso University, Valparaiso, Indiana

Miller, T. H., 1575 Washington Street, San Francisco, Calif.

Mitchell, I. A., Kenyon Transformer Co., Inc., New York, N. Y.

Mowry, C. H., The New York Telephone Co., Brooklyn, New York

Murray, J. S. (Member) Follansbee Brothers Co., Follansbee, W. Va.

Neuschot, R. (Member) Thompson-Starrett Co., Inc., New York City, N. Y.

Nicol, W. C., Hartford Steam Boiler Inspection & Insurance Co., Chicago, Ill.

O'Handley, J. A., Western Electric Co., Kearny, N. J.

Rathbun, V. R., Dept. of Public Utilities, Tacoma, Wash.

Reynolds, F. N. (Member) General Electric Co., Philadelphia, Pa.

Robinson, F. W., Stanton Oper. Co., Pittston, Pa.

Ruddell, L., Kansas City Power & Light Co., Kansas City, Mo.

Schwabacher, G. P., General Electric Co., Bridgeport, Conn.

Seaman, F. D., Dominion Electric Power Ltd., Regina, Sask., Can.

Smith, C. C., General Electric Co., Bridgeport, Conn.

Steates, E. F., 11 Clark Place, Utica, New York

Stevens, O. L. Erie County Electric Co., Erie, Pa.

Stillwell, W. E., Jr., Union Gas & Electric Co., Cincinnati, Ohio

Stone, R. D., State Trade School, Willimantic, Conn.

Stretch, M. W., Westinghouse Elec. & Mfg. Co., Mansfield, Ohio

Thomson, G. T., Hydro Electric Power Commission of Ont., Leaside, Ontario, Canada

Van Horne, J. C., Powell, Wyoming

Wannag, V. E., Western Electric Co., Kearny, N. J.

Welch, W. M., Bell Telephone Co. of Penna., Philadelphia, Pa.

Wold, T., Smith & Stone, Ltd., Georgetown, Ont., Canada

45 Domestic

Foreign

Barnes, H. W., Ferranti Ltd., Aldwych, London, Eng.

Ganpathi, R., The Cochin Electric Co. Ltd., Cochin, South India

Cheryan, P. C., Siemens-Schuchert-Werke A. G., Berlin, Germany

Phillips, F. A., Electrical & Radio Service Co., Hurstville, Australia

Ram, A., Renala Hydro Electric Installation, Renala Khurd, Dist. Montgomery, Punjab, India

Roth, A., Kabelfabrik und Drahtindustrie Aktien-Gesellschaft, Vienna, Austria

Shinohara, K., Ministry of Communication, Tokyo, Japan

Taylor, M. G., c/o Venezuela Power Co., Ltd., Barquisimeto, Venezuela, S. America

8 Foreign

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during May are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

FACHAUSDRÜCKE DER SCHWEISSTECHNIK. Deutsch-Englisch-Russisch. Berlin, V. D. I. Verlag, 1931. 31 pp., 6 x 4 in., paper, 2-r. m.——This little dictionary is intended to supplement the general engineering dictionaries by providing a list of the welding terms in general use, especially those of recent coinage. The book has been compiled by the welding committee of the German Engineering Society and is unusually successful in providing exact equivalents for the terms.

MACMILLAN TABLE SLIDE RULE. By J. P. Ballantine. N. Y., Macmillan Co., 1931. Tables, 11 x 9 in., paper, $.50.——A set of four numerical tables and four slides, by means of which the arithmetic problems that arise in trigonometry and engineering may be solved without calculation. The charts answer the purpose of an ordinary slide rule. Three to four places can be read direct; five or more may be had by interpolation.

RECORDING SOUND FOR MOTION PICTURES. Edit. by Lester Cowan for the Academy of Motion Picture Arts and Sciences. N. Y., McGraw-Hill Book Co., 1931. 404 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth. $5.00.——A textbook upon the technique of making sound pictures, prepared by a number of experts. The equipment for recording and reproducing sound is described in detail, as are also the manipulation of the film and the problems of studio acoustics and of recording. The book is the first to present a systematic account of practise in its field.

MECHANICAL LABORATORY METHODS. 4th edit. By J. C. Smallwood and F. W. Keator. N. Y., D. Van Nostrand Co., 1931. 386 pp., illus., diagrs., charts, tables, 10 x 6 in., cloth, $3.50.——Directions are given for testing and calibrating scales, calorimeters, brakes, fluid meters and other instruments, for analyzing fuels and determining their heat value, and for testing engines, boilers, pumps, refrigerating machinery, lubricants and electrical machinery. The principles underlying the methods are given, and the directions are clear and concise. This edition has been revised and rearranged to conform with modern requirements.

SPONS' ELECTRICAL POCKET-BOOK. By W. H. Molesworth. Lond., E. & F. N. Spon; N. Y., Spon & Chamberlain. 4th edit., 1931. 401 pp., diagrs., charts, tables, 7 x 4 in., leather, $2.50.——Small enough to be carried in a coat pocket, this work of some 400 pages contains a careful selection of material frequently needed for reference by engineers, particularly those engaged in central station work, transmission and railroading.

Theory and Practice of RADIO FREQUENCY MEASUREMENTS. 2nd edit. By E. B. Moullin. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1931. 487 pp., illus., charts, diagrs., tables, 9 x 6 in., cloth. $12.50.——A practical laboratory guide covering all the measurements usually made and giving clear, detailed methods for making them. The new edition has been almost doubled in size and largely rewritten.

ORDER FORM FOR REPRINTS OF FULL PAPERS ABRIDGED IN THIS ISSUE OF *ELECTRICAL ENGINEERING**

(July 1931) Number	Author	Title
☐ 31-4	L. V. Bewley	Traveling Waves on Transmission Systems
☐ 31-9	J. J. Torok	An Experimental Lightning Protector for Insulators
☐ 31-10	R. R. Pittman and J. J. Torok	Lightning Investigation on a Wood Pole Transmission Line
☐ 31-20	Philip Sporn	1929 Lightning Experience on the 132-Kv. Transmission Lines of the Am. Gas and Elec. Co.
☐ 31-42	J. C. Dowell	Attenuation and Successive Reflections of Traveling Waves
☐ 31-57	F. A. Cowan	Recent Developments in the Operation of Overseas Radio Telephone Service
☐ 31-79	Philip Sporn and W. L. Lloyd, Jr.	1930 Lightning Investigations on the Transmission System of the Am. Gas and Elec. Co.
☐ 31-82	C. L. Fortescue and R. N. Conwell	Lightning Discharges and Line Protective Measures
☐ 31-85	Otto Brune and J. R. Eaton	Experimental Studies in the Propagation of Lightning Surges on Transmission Lines
☐ 31-86	I. W. Gross and J. H. Cox	Lightning Investigation on the Appalachian Elec. Pwr. Co.'s Transmission System
☐ 31-87	W. W. Lewis and C. M. Foust	Lightning Investigation on Transmission Lines—II
☐ 31-88	F. W. Peek, Jr.	Lightning, Characteristics—Induced Voltages—Direct Strokes—Coordination—Transmission Line Design
☐ 31-89	Edgar Bell and A. L. Price	Lightning Investigation on the 220-Kv. System of the Penn. Pwr. & Lt. Co. (1930)

*Members, Enrolled Students and subscribers are entitled to one complete copy of any paper abridged if it is requested within one year from date of its publication in ELECTRICAL ENGINEERING. Thereafter charge of twenty-five cents per complete copy will btain.

Selected Items From Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Ammeters

HIGH FREQUENCY. A Method of Comparing Ammeters At Very High Frequencies, C. L. Fortescue and L. A. Moxon. *Sci. Instruments—Jl.*, vol. 8, no. 3, Mar. 1931, pp. 94-97, 5 figs. Considerable difficulty has been experienced in comparing ammeters at frequencies above one million cycles per second with reasonable degree of accuracy; means of overcoming these difficulties are described and final arrangement is reliable up to frequencies of 100 million to within accuracy of 2 per cent.

Brushes

COMMUTATOR. Double Brush-Holders Improve D-C. Machine Operation, A. M. Harrison. *Power*, vol. 73, no. 15, Apr. 14, 1931, pp. 586-587, 3 figs. Under certain conditions use of double brush-holders on d-c. machines is advantageous, while on other machines they may be objectionable.

Cables

PAPER INSULATED. The Manufacture of Lead-Covered Paper-Insulated Telephone Cable, J. R. Shea. *Mech. Eng.*, vol. 53, no. 4, Apr. 1931, pp. 277-283, 17 figs. Particulars regarding new developments comprising direct application of wood-pulp insulation, improved cable stranding, vacuum drying, and central melting of large quantities of lead alloy and its distribution through piping to number of sheathing presses. Before "Three-M" (Management, Materials, Maintenance) Congress, Cleveland, Ohio.

RUBBER INSULATED. Ueber Maschinen zur Herstellung von Kabeln (Machines for Manufacture of Cables), M. Pollman. *Gummi-Zeitung*, vol. 45, nos. 21 and 22, Feb. 20, 1931, pp. 876-877 and Feb. 27, pp. 914-916, 7 figs. Particulars of so-called wire-covering machines of both vertical and horizontal type for covering of thin and thick conductors. See reference to previous articles by author in same journal, in Engineering Index 1930, p. 545, and Engineering Index 1929, p. 603.

SUBMARINE. Some Economic Factors in the Design of Single Core Submarine Cables for Carrier Telephony, J. R. Vezey. *Elec. Communication*, vol. 9, no. 4, Apr. 1931, pp. 217-221, 4 figs. Having decided on length, attenuation, and number of speech channels for any cable, relative proportions of weights of central conductor, dielectric and return conductor to obtain lowest cost can be varied over wide range; further feature, brought out by study, is that maximum length of cable over which it is possible to work fixed number of channels, varies relatively little within limits of practical sizes of core.

TELEPHONE. Buried Tape-Armored Exchange Cable, C. W. Nystrom. *Telephony*, vol. 100, no. 14, Apr. 4, 1931, pp. 22-25, 10 figs. New method of underground exchange construction applicable to suburban residential areas; method and materials used in burying tape-armored exchange cable; cable placed in either hand or machine-dug trench.

Circuits

HIGH-VOLTAGE. A Note on the Timing of Electrically Independent Transient Circuits for High-Speed Oscillographic Work, L. B. Snoddy and J. C. Street. *Gen. Elec. Rev.*, vol. 34, no. 4, Apr. 1931, pp. 258-259, 3 figs. Method for initiating discharge in high-voltage circuits at definite time has been developed and applied to lightning generator voltages up to 430 kv.; method uses combination of over-voltage and irradiation by ultra-violet light; it has advantage that it requires no electrical connection between tripping circuit and high-voltage side of impulse circuit.

Circuit Breakers

ELECTRIC. Oil-Less Switchgear. *Elecn. (Lond.)*, vol. 106, no. 2760, Apr. 24, 1931, pp. 611-612, 3 figs. Siemens-Schuckert works and A. E. G. have, as result of experimental work in their laboratories, put on to market high capacity oil-less switches, thus showing their confidence in methods by which they have tackled problem; switches of both these types were on view at Leipzig Technical Fair.

Conductivity

The Electrical Conductivity of Some Bismuth Alloys at Low Temperatures, J. C. McLennan, J. F. Allen and J. O. Wilhelm. *Roy. Soc. Canada—Trans.*, vol. 24, pt. 1, section 3, May 1930, pp. 25-32, 1 fig. Investigation to find how superconducting point of lead would be affected by alloying this metal with bismuth and with antimony; also to determine superconducting point of some of fusible alloys of which bismuth is constituent. Bibliography.

Control

CHEMICAL PLANTS. Centralized Control Improved Production, A. J. A. Peterson, *Instruments*, vol. 4, no. 2, Feb. 1931, pp. 51-53, 2 figs. Large chemical plant in Niagara Falls applied to its problem of machine and load control, same principles used in central station industry; in this plant, operator must control and supervise 10 to 14 manufacturing units, all forming heavy electrical loads, and must supervise incoming supply as well.

ELECTRIC HEATING. Radiation-heating Control, C. G. Heys Hallett. *Elec. Rev.*, vol. 108, no. 2785, Apr. 10, 1931, pp. 626-627, 4 figs. Remarkable economies in current consumption and gains in personal comfort result from use of radiation thermostat or "Eupatheostat" as compared with ordinary air thermostat.

Controllers

Misapplications of Control Equipment, H. C. Jenks. *Indus. Eng.*, vol. 89, no. 3, Mar. 1931, pp. 110-113, 4 figs. Putting control equipment in service for which it was not designed frequently causes trouble; practical discussion of control equipment breakdown and methods of prevention.

Currents

HAZARDS. Note sur la tension non dangereuse des courants électriques (Safe Voltages of Electric Currents), Feraud. *Société Francaise des Electriciens—Bul.*, vol. 1, no. 3, Mar. 1931, pp. 288-301 and (discussion) 302-305. Qualitative definition of safe voltages; influence of characteristics of source on hazards, influence of outside circumstances at source on hazards; dangerous current; quantitative analysis of safe voltages; conclusions.

Dielectrics

X-RAY ANALYSIS. X-Ray Studies of Motions of Molecules in Dielectrics Under Electric Stress, R. D. Bennett. *Franklin Inst.—Jl.*, vol. 211, no. 4, Apr. 1931, pp. 481-487, 7 figs. Experiments at Ryerson Physical Laboratory lead to conclusion that molecular group state of liquid is accentuated as liquid solidifies leading to definite crystalline structure, which can be strongly oriented by electric field; it is concluded that X-ray methods may prove useful tool in investigation of molecular motions in dielectrics.

Electricity

Electricity—What It Is and How It Acts—L, A. W. Kramer. *Power Plant Eng.*, vol. 35, no. 9, May 1, 1931, pp. 514-516. Electron and proton as factors in explaining radiation from sun and stars.

Electric Drive

BLOOMING MILLS. 5000 Hp. D-C. Motor Drives New Algoma Rail and Structural Mill, A. F. Kenyon, *Elec. News*, vol. 40, no. 7, Apr. 1, 1931, pp. 54-56, 4 figs. Demands of Canadian railways for longer and heavier steel rails has necessitated complete rebuilding and electrification of the rail and structural mill of Algoma Steel Corporation, Sault Ste. Marie, Ont.; initial rolling of 26 in. x 26 in.—13,500 lb. ingots is in electrically driven 35 in. reversing blooming mill, ingots being reduced to 10 in. x 10 in. and smaller blooms, depending upon product being rolled in finishing mills.

PAPER AND PULP MILLS. New Mill Drive at Smith Paper Co. Aids Heat Balance, R. A. Packard. *Power*, vol. 73, no. 13, Mar. 31, 1931, pp. 504-506, 6 figs. Synchronous motor on turbine shaft permits unit to be governed by low-pressure steam demand; surplus or efficiency of power being taken by utility system; diagram of steam distribution at Columbia mill; diagram of main electrical connections.

PUMPS. Selecting the Motor to Suit the Pump, E. C. Dieffenbach. *Power*, vol. 73, no. 17, Apr. 28, 1931, pp. 656-659, 6 figs. Starting conditions and nature of various loads determine motor and control; to choose wisely, both motor and pump characteristics must be understood; drives for reciprocating, centrifugal, rotary and screw pumps are discussed; characteristic curves.

ROLLING MILLS. Modernizing Rolling Mills Electrically. *Iron and Steel Industry*, vol. 4, no. 7, Apr. 1931, pp. 235-238, 4 figs. Examples of modern main drives for rolling mills carried out by English Electric Co.; sheet-mill and merchant-mill drive; large motor for Brown Bayley and Co.; exciter set for mill motor; strip mills and cold-roll drives; heating of sheet-mill rolls; special tube-mill installation; frequency standardization; switchgear.

WIRE DRAWING MACHINES. Electric Equipment for Wire Drawing, T. R. Rhea. *Wire*, vol. 6, no. 5, May 1931, pp. 165-167-170 and 185, 8 figs. Various types of machines and type of motors and control which experience has determined as most suitable.

Electric Equipment

AUTOMOBILES. Modern Electric Equipment of Motor Vehicles, V. A. Karpov. *Electritchestvo*, no. 2, Feb. 1931, pp. 69-76, 10 figs. Systematic review of electric equipment of motor cars, tractors, and motorcycles; typical schemes of electric equipment for modern motor vehicles of different systems applied in U.S.S.R. and other countries; power-supply systems and electric accessories are critically described. (In Russian.)

MAINTENANCE AND REPAIR. Maintenance Methods for Electrical Equipment, E. L. Richards. *Power Plant Eng.*, vol. 35, no. 6, Mar. 15, 1931, pp. 360-362, 3 figs. Systematic maintenance schedule insures against shutdowns and anticipates repair work; importance of inspection schedule and records; maintenance record forms.

Electric Lines

HIGH TENSION DESIGN. Design of 110- and 132 Kilovolt Steel Tower Transmission Lines. *Nat. Elec. Light Assn.—Report*, no. 17, Mar. 1931, 16 pp., 3 figs. Condensed discussion of more important factors entering into design of 110- and 132-kv. steel tower transmission lines showing what items enter into transmission line specification together with some indication of typical practise with respect to each item, *i. e.*, location, electrical clearances, conductors, tower loading, transmission tower specifications; insulation; telephone lines.

PROTECTION. Protection of Rural Lines. *Elecn. (Lond.)*, vol. 106, no. 2760, Apr. 24, 1931, p. 610. Discussion by Overhead Lines Association on control and protection of rural lines; standard nomenclature is needed; oil and air break switches compared. Before Instn. Elec. Engrs.

Electric Power

RAYON PLANTS. Electrification of a Rayon Mill. *Elec. Times*, vol. 79, no. 2055, Mar. 12, 1931, pp. 473-475, 6 figs. Power generation and distribution in Sunsheen's Mills, Ballymena, Ireland, with special reference to problem of cabling and wiring; current is generated by means of two steam-driven turbine-generators, main unit of 820-kw. output, at 400 volt, 50 cycle, three-phase, neutral point being brought out, so as to provide 230 volts for lighting; second turbine set is of 100 kw.; steam is raised in three Lancashire boilers 8 ft. by 30 ft., working at 180-lb. pressure and superheated 150 deg. fahr.

Electric Towers

TESTING. Testing Full-Size Transmission Towers, N. B. Obbard. *Eng. News-Rec.*, vol. 106, no 18, Apr. 30, 1931, pp. 735-737, 4 figs. Description of plant of American Bridge

Co., in Pittsburgh, equipped to test towers up to 100 ft. in height, either on fixed grillage or on their own earth anchors; wind and conductor loads applied simultaneously at as many as seven points by pulling rig actuated by 50,000-lb. mechanical screw.

Electrodes

POTENTIALS. The Nernst Equation—A New Equation for Electrode Potentials—1, M. Meyer. *Chem. News*, vol. 142, no. 3701, Mar. 20, 1931, pp. 179-183, 2 figs. Many corrections have been applied to concentration of "active" material in effort to secure better agreement; all save "activity" coefficient fail; textbooks still make curious comments about equation; since electromotive force measurements may be made with great precision it may be of interest to examine some and also another possible equation which, however, because of its nature, seems only of academic interest.

Engineering

BUSINESS RELATIONS. Shall We Revise Our Conceptions of Engineering Functions, L. E. Jermy, *Machine Design*, vol. 3, no. 5, May 1931, pp. 23-25, 2 figs. Study of relationship and responsibilities of engineer to principal departments of industrial organization; chart illustrates relationships of chief engineer.

EDUCATION. A Suggestion for Engineering Education, L. E. Moore, *Boston Soc. Civil Engrs.—Jl.*, vol. 18, No. 4, Apr. 1931, pp. 95-102. Development of engineering education; engineering specialties; search for school to meet ideals for training; suggested course for students in engineering, natural philosophy, and sciences; author criticizes existing system for turning out men who are too often narrow technicians instead of scientifically educated gentlemen, capable of taking hold of any branches of applied science and by study specializing in them.

INFLUENCE ON CIVILIZATION. Technology and Material Progress, W. R. Whitney, *Science*, vol. 73, no. 1877, May 8, 1931, pp. 483-486. It is claimed that accumulated data of all material progress never were so great and never so uniformly appreciated; those who are interested in technical progress look at it as continuous, but do not necessarily overrate its importance; there must be parallel advance for higher values in man. Before Am. Philosophical Soc.

Engineers

RESPONSIBILITY. The Responsibility of the Engineer, R. V. Wright. *Engrs. and Eng.*, vol. 48, no. 4, Apr. 1931, pp. 73-75. Economist as well as engineer has been sticking too much to cold facts and seems to have overlooked fact that most precious factor in industry, human element, must be handled in entirely different way from materials and natural forces; now great problem of engineer is to deal with human life in industry. Before Engrs. Club.

Exciters

TURBO-GENERATORS. Turbo-Generator Exciters, W. Sharp. *Elec. Times*, vol. 79, no. 2059, Apr. 9, 1931, pp. 659-660, 6 figs. Probable lines of progress and subsequent developments in connection with manufacture of turbo-generator exciters; subject as direct bearing upon possibility and advisability of making continuous-current exciter remote from turbo-generator.

Furnaces

ANNEALING. Electric Annealing of Aluminum. *Foundry Trade Jl.*, vol. 44. no. 763, Apr. 2, 1931, p. 244, 1 fig.; see also *Metal Industry (Lond.)*, vol. 38, no. 14, Apr. 3, 1931, p. 364, 3 figs. and *Mech. World*, vol. 89, no. 2310, Apr. 10, 1931, p. 343. To facilitate precise annealing of aluminum sheets on large scale, General Electric Co., has installed large single-track multi-car type electric annealing furnace which has effective hearth area 24 ft. long by 7 ft. 5 in. wide in works of Aluminum Corp., Dolgarrog, Carnarvonshire; furnace has electric loading of 150 kw., heating elements arranged to ensure phasal balance on 440-volt, 3-phase, 50-cycle supply.

HEAT TREATING. Bright Anneals in Artificial Atmospheres, J. C. Woodson. *Elec. Jl.*, vol. 38, no. 4, Apr. 1931, pp. 246-247, 3 figs. Possibilities of annealing in artificial atmospheres, which process is still in development stages, are not known; however, certain surface conditions can be obtained that reduce number of subsequent operations and greatly increase die life and reduce machine work; various types of electric furnaces are illustrated.

STEEL MAKING. Montreal Plant Produces Electric Furnace Steel in Large Quantities. *Can. Machy.*, vol. 42, no. 5, Mar. 5, 1931, pp. 27-30, 5 figs.; see also *Iron and Steel Canada*, vol. 14, no. 2, Feb. 1931, pp. 30-32, 3 figs. Canadian Tube and Steel Products, Ltd., Montreal, has become independent for their steel ingot and rod requirements through installation of electric steel-melting furnaces; installation consists of two Volta furnaces of Heroult type; electrode arrangements; furnace tilting; oxidation and reduction; low voltage use; ingot stripping.

Generators

HIGH-VOLTAGE. New Surge Generator. *Elec. Jl.*, vol. 28, no. 4, Apr. 1931, p. 245, 2 figs. Trend toward increased insulation for given operating voltage has necessitated higher and higher testing voltages in recent years; improved equipment to provide 1,000-kv. 60-cycle, and 3,000-kv. surge voltages has therefore been installed at Trafford High Voltage Laboratory; new equipment will greatly facilitate development work on insulation, as it is now necessary to determine performance on lightning voltages of all high-voltage apparatus.

High-Voltage Surge Testing, F. R. Benedict. *Elec. Jl.*, vol. 28, no. 4, Apr. 1931, pp. 216-218, 10 figs. In performing high-voltage surge tests on apparatus it is essential that shape of surge generator wave be under accurate control; steepness of wave front, magnitude of crest, and duration of tail can all be varied by use of proper circuit constants; elimination of oscillations at crest of wave is of considerable importance from standpoint of voltage measurement.

Grounding

CABLES. Der Doppelerdschlusstrom in Drehstromkabeln und seine Einwirkung auf benachbarte Fernmeldekabel (Double Ground Current in Three-Phase Cables and its Effect on Nearby Telephone Cables), W. Wild. *Wissenschaftliche Veroeffentlichungen aus dem Siemens-Konzern*, vol. 10, 1931, pp. 51-77, 25 figs. Origin is studied on basis of equivalent circuit diagrams; it is concluded that, with consideration of loads already present before occurrence of double ground, networks fed from one end are to be considered as networks fed from either end; protection is deduced from impedance diagrams; study of harmonics. Bibliography.

Heating

BUILDINGS. Building Heating. *Elec. Rev.*, vol. 108, no. 2786, Apr. 17, 1931, pp. 689-690, 3 figs. Advantages of load are such as to justify low rates; notes on electrode boiler and thermal storage; tabular and panel heating; electricity and heating load.

Hydroelectric

PIPE LINES. Design of Pipe lines for Hydroelectric Plants, J. S. Carpenter. *Power Plant Eng.*, vol. 35, no. 7, Apr. 1, 1931, pp. 418-419. To secure most economical design of pipe line for given condition, diameter and thickness are figured by modification of Enger's formula.

POWER PLANTS. The Economics of Power Plant Design, H. G. Acres. *Elec. News*, vol. 40, no. 7, Apr. 1, 1931, pp. 36-38 and 47, 8 figs. Fixed charges and operating expenses should be considered as definite factors in design of all plants; this is well illustrated in design and construction of recently completed development for municipality of Edmundston, New Brunswick.

Hydroelectric Units Operated as Condensers, H. A. Von Eiff. *Power*, vol. 73, no. 17, Apr. 28, 1931, pp. 666-669, 5 figs. Operating hydroelectric units as synchronous condensers under certain load conditions offers possibilities of large economies in plant operation; units in Holtwood plant of Pennsylvania Water and Power Company operated as condensers; method of solving problems encountered in operation and saving attained from condenser operation; curves of water saving by condenser operation on 25-60 cycle system; power for condenser operation.

Automatic Operator for 60,000-Hp. Station, A. C. Clogher and E. N. Peterson. *Elec. World*, vol. 97, no. 16, Apr. 18, 1931, pp. 716-722, 7 figs. Control of system frequency, division of load between units and change of one unit from generator to condenser operation are automatically and very successfully performed at Morony hydroelectric development of Montana Power Co.; station is located on Missouri River about 18 mi. below Great Falls, Mont.; two 22,500-kw. units are installed.

Rock Island—A Power Development on the Columbia River, T. B. Parker. *Elec. Light and Power*, vol. 9, no. 5, May 1931, pp. 22-27, 7 figs. Hydroelectric development is being built for Washington Electric Co., subsidiary of Puget Sound Power & Light Co., principal distributor of power in western Washington; it will be first large low-head development in Northwest; designed for ultimate capacity of 150,000 kw. under normal head of 48 ft.; initial installation will be 60,000 kw.

Industrial Progress

RUSSIA. Russia, H. L. Cooper. *Engrs. and Eng.*, vol. 48, no. 4, Apr. 1931, pp. 76-86. How communism has come about, as told by consulting engineer for 800,000-hp. hydroelectric and navigation project under construction on Dnieper River in Russia; statistics of Dniebrostroi hydroelectric projects; organization and how work is being done; statistics about Dnieprostroi hydroelectric development; notes on Five-Year Program.

Insulation

The Physics of Insulating Materials—V, A. M. Thomas. *World Power*, vol. 15, no. 88, Apr. 1931, pp. 307-310. Failure of dielectrics under stress; discharges in solids; mechanical deformation of dielectric due to electric force. Bibliography.

LINES, HIGH TENSION. Performance of Wood Insulation in Transmission Lines, F. E. Andrews. *Elec. World*, vol. 97, no. 17, Apr. 25, 1931, pp. 780-782, 5 figs. No interruptions due to lightning flashover as indicated by line trip-outs and no cases of 60 cycle power arcs following lightning flashover are recorded for 1930 on 90 mi. of all-wood constructed 33-kv. lines on Public Service Co. of Northern Illinois' system; this performance compares with respective figures of 42 and 30 for same items per 100 miles of line on 1025 mi. of previous construction.

MACHINERY. What is Good Insulation on Electrical Machines, J. L. Rylander. *Power*, vol. 73, no. 11, Mar. 17, 1931, pp. 438-441, 5 figs. Insulation failure is common evil of all electrical equipment; outline of methods for determining failure when cleaning and drying of electrical machine; effect of moisture and temperature; insulation values of different types of electrical machines as determined by tests.

MICA. The Permittivity and Power Factor of Micas, C. Dannatt and S. E. Goodall. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 412, Apr. 1931, pp. 490-496, 5 figs. Attention is drawn to electrode difficulty in testing mica, and tests are described which show order of contact effect which may be obtained with ordinary mercury electrodes; means are described by which electrode contact effect with mica may be entirely eliminated, and test results are given proving this point; test results on power factor and permittivity of ruby, green, and amber micas are given.

Light and Lighting

HIGHWAY. Illuminated Highways are Safer, D. M. Diggs. *Nat. Safety News*, vol. 23, no. 5, May 1931, pp. 19-20, 58 and 60, 5 figs. Examples showing that modern highway lighting lessens dangers that lurk in darkness and aids night travel.

INDUSTRIAL. Maintenance of the Illumination System of an Industrial Plant, R. C. Smith. *Mech. Eng.*, vol. 53, no. 5, May 1931, pp. 371-375, 6 figs. Details and results of efficiency and depreciation study of shop-lighting fixtures undertaken to obtain definite data upon which to base recommendations regarding lamp renewals and cleaning schedules. Before "Three-M" (Management, Materials, Maintenance) Congress, Cleveland, Ohio, previously indexed from advance paper.

MEASUREMENT. The Photoelectric Cell and Electric Clock as a Means of Recording the Daily Hours of Bright Sunshine, W. A. Thomson. *Can. Jl. Research*, vol. 4, no. 3, Mar. 1931, pp. 299-303, 2 figs. Method is presented whereby accurate record of daily hours of bright sunshine is made by electric clock, controlled, through relay, by intensity of light incident upon cathodes of suitably exposed photoelectric cell.

Lightning

MEASUREMENTS. Instruments for Lightning Measurements, C. M. Foust. *Gen. Elec. Rev.*, vol. 34, no. 4, Apr. 1931, pp. 235-246, 35 figs. Latest developments and applications of surge-voltage recorders; cathode-ray oscillographs; lightning-stroke recorders; surge indicators; lightning-severity meter.

Lightning Arrester

The Theory of Surge Absorbers, J. M. Thomson. *Elec. News* vol. 40, no. 9, May 1, 1931, pp. 41-42, 2 figs. Device that is essentially air core inductance connected in series with line, close to apparatus to be protected, and is operated by wave-front steepness of surge.

Magnetic Testing

IRON AND STEEL. Non-Destructive Tests by the Magnetic Dust Method, A. V. deForest. *Iron Age*, vol. 127, no. 20, May 14, 1931, pp. 1594-1595, 2 figs. Methods using magnetized iron filings for detecting cracks in ground surfaces, fatigue cracks in forgings and defects in seamless tubing; reference to work by W. E. Hoke and T. R. Watts. Before Am. Soc. Steel Treating and Am. Welding Soc.

Motor-Generators

Automatic Emergency Generating Sets, D. A. Bower. *Power Engr.*, vol. 26, no. 300, Mar. 1931, pp. 86-89 and 109, 5 figs. Sources of emergency supplies; development of emergency generating sets; principle of operation; general arrangement of emergency flywheel generating set; emergency set performing mechanical work; general layout of flywheel generating set arranged normally to perform mechanical work.

Motors

FRACTIONAL HORSEPOWER. The Woods High-Torque Fractional Horse-Power Motor, *Engineering*, vol. 131, no 3408, May 8, 1931, p. 604, 3 figs. This type of motor has disadvantage of requiring commutator, which introduces complication that may easily lead to breakdown; moreover, to short-circuit rotor windings when motor has run up to speed, it is necessary to employ either brush-lifting device or segmental brush; to overcome disadvantages M. W. Woods, London, have designed line of machines in outputs ranging from 1/8 to 1/4 hp. at speeds of from 2800 to 700 r. p. m.

STANDARDIZATION. Adaptable Electric Motors, E. G. Ross, *Elec. Rev.*, vol. 108, no. 2786, Apr. 17, 1931, pp. 664-665, 1 fig. Analysis of "special" requirements of mechanical firms shows that they can be so classified as to render perfectly feasible issuance of British Standard Specification covering exterior shapes of motors of from 1-hp. to 250-hp. rating, while simultaneously making clear that any radical production alterations are not involved.

Networks

DESIGN. Network Promises Marked Economies, D. K. Blake. *Elec. World*, vol. 97, no. 11, Mar. 14, 1931, pp. 492-495, 10 figs. Network principle promises to reduce light and power system cost and to improve service standards if it is applied to several voltage levels used in industry, simplifies system layout and engineering, makes possible manufacture of standard apparatus of single rating on production scale and reduces system investment per unit of capacity and improves service standards at minimum cost.

An A-C. System of Distribution, J. P. Heslop. *Elec. Rev.*, vol. 108, no. 2783, Mar. 27, 1931, p. 544, 2 figs. System described is claimed to possess flexibility and economy of a-c. with reliability of d-c. operation; oil circuit breakers ar installed in power station only, adjacent substations being supplied from different feeders.

Designing 115-230 Volt Distribution for Modern Residential Districts, G. L. Lillie. *Elec. News*, vol. 40, no. 9, May 1, 1931, pp. 37-40 and 50, 10 figs. Fundamentals of economical service outlined; transformers should be spaced 400-600 ft. apart; secondary conductors vary from no. 0 to no. 0000.

INTERCONNECTED. Transmission and Interconnection, P. M. Downing. *Elec. Light and Power*, vol. 9, no. 5, May 1931, pp. 20-21. California's experience in diversity, load factor, rural electrification and percentage of homes wired is direct criterion of country-wide results to be expected from extension of transmission lines and their interconnection.

Phase Advancers

The Theory and Performance of Phase Advancers, J. J. Rudra and M. Walker. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 412, Apr. 1931, pp. 445-469 and (discussion) 469-486, also author's closure 486-489, 52 figs. Advancers are divided into "expedor" advancers in which voltage is proportional to secondary current, and "susceptor" advancers in which it is proportional to secondary voltage; effect of these are considered when connected to ideal motor having circle diagram of infinite radius and sets out simple relations between angle of advancer and kva. required to do what is desired.

Photoelectric Cells

Progress in Photoelectric Cells, A. J. McMaster. *Radio Industries*, vol. 5, no. 12, Apr. 1931, pp. 597-598 and 612-618, 3 figs. Types of light sensitive cells; theory of photoelectric action; cell manufacture; application; operating requirements.

Potentiometers

An Improved Feussner Type Potentiometer, M. Eppley and W. R. Gray. *Rev. Sci. Instruments*, vol. 2, no. 4, Apr. 1931, pp. 242-249, 7 figs. There are two improvements in design that can be made, one to both earlier and later forms as currently imported into United States, other to later self-checking type only; they are elimination of six contact resistances affecting measuring circuit, and addition of another standard cell dial, making it possible to adjust standard cell circuit to five places instead of to only four.

Power Factor

Checking Reverse Relay Connections, C. F. Dalziel. *Elec. West*, vol. 66, no. 4, Apr. 1, 1931, pp. 180-181, 2 figs. Most expedient method of over-all check is to connect voltmeter and ammeter in circuit with wattmeter, and from readings taken as outlined, sufficient data are obtained in order to permit power factor and "system" present to be computed; wattmeter readings obtained using voltage from potential terminals of relay. (Concluded.)

Controlling Power Factor Automatically, A. Smith. *Power*, vol. 73, no. 16, Apr. 21, 1931, pp. 632-634, 5 figs. By proper selection of motors in large industrial plant it is possible, by automatically controlling field current of large synchronous motor, to maintain plant power factor at unity; favorable power rate is obtained because of high power factor and other operating conditions; charts of power factor, incoming plant kilowatts and voltage recorded by graphic instruments; operating results.

IMPROVEMENT. Synchronous Motors Will Solve the Power Factor Problem. *Ry. Elec. Engr.*, vol. 22, no. 4, Apr. 1931, pp. 100-101 and 114, 1 fig. Modern machines combined with simplified control equipment have resulted in many successful applications that were once considered impracticable.

MEASUREMENT. Simple Power-Factor Measurement, O. Wiemer. *Elec. West*, vol. 66, no. 4, Apr. 1, 1931, pp. 186-187, 2 figs. If only instrument available is a-c. ammeter of suitable range, it is still possible and often very convenient to make power factor test; this can be done by three-ammeter method; method does not necessarily require use of three separate ammeters as name would seem to imply; equally satisfactory results can usually be obtained with only one ammeter if few simple precautions are taken.

Power Supply

RURAL. Rural Electrification Progresses in Illinois, R. Boonstra. *Elec. World*, vol. 97, no. 15, Apr. 11, 1931, pp. 693-694. Progress in rural electrification made by Public Service Co. of Northern Ill. during 1930 indicates that much can be done even in a bad business year in extending lines to farm customers and in promoting use of energy by those customers.

Radio

AMPLIFIERS. A New Method of Testing for Distortion in Audio-Frequency Amplifiers, H. J. Reich. *Instn. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 401-415, 12 figs. Periodic voltage wave consisting of series of straight lines is distorted into series of curves when it passes through amplifier which gives nonuniform amplification; as such distortion can very readily be detected visually with oscillograph, it affords means of testing for uniformity of amplification; mathematical analysis shows that "saw-tooth" voltage wave is distorted into series of exponential curves in passing through resistance-capacity-coupled amplifier.

ANTENNAS. Radio Antennas, E. F. Martin. *Radio Eng.*, vol. 11, no. 4, Apr. 1931, pp. 39-41, 7 figs. Theory of antenna arrangements; their properties of transmission and reception.

BEACONS. A Radio Beacon and Receiving System for Blind Landing of Aircraft, D. Diamond and F. W. Dunmore. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 4, Apr. 1931, pp. 585-626, 29 figs., partly on supp. plate. Receiving system for use at airports to permit blind landing of aircraft under conditions of no visibility; system comprises three elements to indicate to pilot position of aircraft as it approaches and reaches instant of landing; same medium-frequency receiving set required for obtaining radiotelephone and radio range beacon service on airways is utilized for receiving runway localizing and marker beacon signals.

COILS—RESISTANCE. The High-Frequency Resistance of Coils, A. L. Green. *Experimental Wireless*, vol. 8, no. 91, Apr. 1931, pp. 183-191, 6 figs. It is shown that there are methods of measuring high-frequency resistance of coils which do not require use of thermo-junction and calibrated resistances; these methods depend on condition for oscillation in triode assembly, and simplest of them uses dynatron oscillator.

OSCILLATORS. Calculation of Electric and Magnetic Field Strength of any Oscillating Straight Conductors, R. Bechmann. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 3, Mar. 1931, pp. 461-466, 1 fig. Theoretical mathematical analysis from results obtained by use of method which depends on formation of Hertzian vectors.

RECORDERS. An Automatic Recorder of Signals from A Rotating Beacon Transmitter, R. L. Smith-Rose and H. A. Thomas. *Sci. Instruments—Jl.*, vol. 8, no. 3, Mar. 1931, pp. 81-88, 5 figs. Automatic apparatus which has been developed for recording of wireless bearings from rotating beacon transmitter of type now in operation at Orfordness, Suffolk; output telephone signal current from standard type of valve receiver is supplied to tuned audio-frequency amplifier followed by rectifier; output current from this rectifier operates relay and pen which traces line record upon sheet of paper placed on rotating drum.

TRANSFORMERS. The Resistance Capacity Coupled Transformer, F. Aughtie. *Experimental Wireless*, vol. 8, no. 91, Apr. 1931, pp. 177-182, 7 figs. Use of choke in anode circuit and transformer primary being fed through suitable coupling condenser has long been known and used; authors favor circuit of where choke is replaced by resistance, by this substitution, besides removal of potential source of distortion, in shape of additional iron core, smaller self capacity of resistance as compared with choke, renders possible improvement in performance of stage at high frequencies.

ULTRA-SHORT WAVE. Ultra Short-Wave Radio-Telephony. *Elec. Rev.*, vol. 108, no. 2785, Apr. 10, 1931, pp. 622-623, 4 figs. Dover-Calais demonstration of radio-telephony on 18-cm. wave-length which marks striking advance in technique of electro-optical directive operation.

A New Wireless System. *Engineer*, vol. 151, no. 3926, Apr. 10, 1931, p. 413, 5 figs. Demonstration was given on Mar. 31 by International Telephone and Telegraph laboratories of "Le Matériel Téléphonique," of Paris; by means of new wireless telephone and telegraph equipment, largely developed by French engineers, in Paris laboratories, two-way telephone communication was established between Dover and Calais, on wavelength as low as 18 cm.

Railroad

ELECTRIFICATION. Suggestions as to the Future of Railroad Electrification, F. H. Shepard. *New York Railroad Club—Off. Proc.*, vol. 41, no. 5, Mar. 1931, pp. 9561-9653. Future outlook of electrification in America; reasons for extension.

Heavy Electric Traction Progress in America, C. Kerr, Jr. *Tramway and Ry. World*, vol. 69, no. 19, Apr. 16, 1931, pp. 187-190, 8 figs. Brief review of two outstanding installations; design, construction and operating developments in locomotives motor development; control improvements; Deion trolley breakers, frequency changer sets.

POWER FACTOR IMPROVEMENT. Importance of Power Factor Improvement, W. K. Fuzzelle. *Ry. Elec. Engr.*, vol. 22, no. 3, Mar. 1931, pp. 75-76 and 83. Transmission and distribution systems loaded with wattless current cannot function economically; remedy lies in wider application of synchronous motor.

Rating

ELECTRIC MACHINERY. New Ratings for Electrical Machinery. *Elec. World*, vol. 97, no. 15, Apr. 11, 1931, p. 679. Recommendations of International Electrotechnical Commission proposed for international use at recent seventh plenary meeting, held in Stockholm *i. e.*, internationally specified limits of temperature rise for rotating machines and transformers; temperature rises reduced for use in tropical climates; tolerances allowable in electrical machine ratings.

Reactive Power

ELECTRIC METERING. Reactive Kva. Metering—VII, E. C. Goodale. *Elec. West*, vol. 66, no. 4, Apr. 1, 1931, pp. 181-183, 3 figs. Effect of unbalanced load upon accuracy of registration of three-phase three-wire reactive meters.

Rectifiers

CONTROL. On the Contact Conduction and Rectification, G. Hara. *Ryojun College of Eng.—Memoirs*, vol. 3, no. 4-A, 1931, pp. 223-224, 19 figs. Author intends to deduce approximate formula for contact conduction applying cold emission theory to contact, and also to make clear mechanism of contact and rectification. Bibliography. (In English.)

Resistance

GROUND. The Measurement of Earth Resistances, G. F. Tagg *Elec. Times*, vol. 79, no. 2061, Apr. 23, 1931, pp. 741-743, 6 figs. Regulations as to earthing; systematic tests; elementary methods of measurements; three point method; bridge methods; fall of potential method; Siemens-Halske earth tester; meggar earth tester; specific resistance of earth.

MOISTURE FILMS. Electrical Resistance of Moisture Films on Glazed Surfaces, G. G. Smail, R. J. Brooksbank, and W. M. Thornton. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 411, Mar. 1931, pp. 427-436, 15 figs. Research is described in two parts, first dealing with relations between surface resistivity, humidity and temperature, and second with influence of gas pressure, both having for their object discovery of laws of film formation under controlled conditions.

Spark Gaps

ELECTRODES. The Development of an Electron Emitting Alloy, O. S. Duffendack, R. A. Wolfe and D. W. Randolph. *Electrochem. Soc.—Advance Paper*, no. 59-17, Apr. 27, 1931, pp. 157-173, 11 figs. After many experiments, nickel alloy containing barium has been developed which is homogeneous in composition and readily reproducible; spark gaps having electrodes made of this alloy have very constant sparking voltages; alloy has marked electron emitting properties that make it valuable for use in various electrical devices; its uses in several ways are being developed.

Stability

ALTERNATORS. Power System Stability, F. A. Hamilton, Jr. *Eng. Jl.*, vol. 14, no. 4, Apr. 1931, pp. 227-242, 31 figs. Methods of predicting power limits under steady or transient conditions have been outlined in various publications and are available to system designers; paper presents in more elementary fashion certain concepts upon which these methods are based; factors which affect power limits are discussed and their interrelation illustrated; methods of increasing power limits are discussed.

Starting

ELECTRIC MACHINERY. The Starting Motors, J. Sachs. *A EG Progress*, vol. 7, no. 4, Apr. 1931, pp. 85-91, 11 figs. Starting processes obtaining with asynchronous and synchronous machines when employing starting motors; it is indicated by few examples that with large machine units, but particularly phase advancers, employment of starting motors exercises very favorable effects upon starting conditions, such as smaller apparent power consumption, smaller initial current surges and higher power factor.

Substations

RECTIFIER. La sous-station automatique d'éclairage de Cannes (Automatic Substation). *Genie Civil*, vol. 98, no. 5, Jan. 31, 1931, pp. 117-118, 4 figs.; see also brief translated abstract in *Power Engr.*, vol. 26, no. 301, Apr. 1931, p. 156. Equipment of Bergerie, Cannes substation converts 10,000-volt three-phase, 25-cycle supply into continuous current at 250 volts for lighting and general service; in order to avoid noise or other nuisance, mercury-vapor rectifier was adopted as converting equipment.

Switchboards

SPECIFICATIONS. Nema Panelboard and Distribution Board Standards. *Nat. Elec. Mfrs. Assn.—Pub.*, no. 31-4, Jan. 1931, 31 pp., 11 figs. Standards on design and construction of panelboards; switchboards; cabinets and equipment boxes; commercial standard practise.

SUPERVISORY CONTROL. Supervisory Control Equipment. *Elec. Rev.*, vol. 108, no. 2784, Apr. 3, 1931, p. 611, 2 figs. Supervisory equipment for remote control of three substations, two of rotary type for traction purposes and one of transformer type, of Auckland Electric Power Board in New Zealand, has recently been completed by Automatic Telephone Manufacturing Co., Ltd., in collaboration with Metropolitan-Vickers Electrical Co., Ltd.; descriptive details of apparatus is given.

Switchgear

LOSSES. Eddy Current Losses in Heavy Current Switchgear—II, J. E. Shaw. *World Power*, vol. 15, no. 88, Apr. 1961, pp. 295-299, 8 figs. Iron loss in mold steel, switch tops; experimental results of measurements discussed in detail; experimental investigation of iron loss in plate, due to single conductor carrying current definite distance from it. (Concluded.)

Synchronizers

CLOCKS, ELECTRIC. Ein funkenfreier Synchronisier-Apparat fuer Nach- und Voreilen (Spark Free Synchronizer for Lagging and Advanced Currents), H. Bock. *Zeit. fuer Instrumentenkunde*, vol. 51, no. 4, Apr. 1931, pp. 197-204, 5 figs. Synchronizing equipment, for electric pendulum clocks, is detailed.

Television

QUALITY. Quality of Television Images, D. K. Gannett. *Bell Laboratories Rec.*, vol. 9, no. 8, Apr. 1931, pp. 358-362, 5 figs. Since each cycle represents two picture elements, number of picture elements which could be received is 10,000 in second, or 625 in 1/16 of second; no matter how good television apparatus, therefore, no better quality picture could be obtained than containing 625 elements, or about 22 by 28 elements.

Transformers

Recent Progress in Large Transformers, R. M. Charley. *Instn. Elec. Engrs.—Preprint*, for mtg., Apr. 16, 1931, 15 pp., 16 figs. General description of progress made in recent years and examples illustrating present stage of art.

Ultra Violet

WINDOW GLASS. Glasses for Use with Invisible (Ultra-Violet and Infra-Red) Rays, S. English. *Jl. of Good Lighting*, vol. 24, Feb. 1931, pp. 27-31 and (discussion) 32-35, 13 figs.; see also *Nature (Lond.)*, vol. 127, no. 3200, Feb. 28, 1931, pp. 310-312, 2 figs. Nature of invisible rays; spectrum; characteristics of certain radiations; ultra-violet transparencies of two glasses of similar composition; relative transparency of various glasses; ultra-violet transmission of various window glasses; effect of artificial aging on two types of ultra-violet glass; spectra of various ultra violet light sources; Wood's glass and fluorescence; light transmission and heat absorption of various glasses.

Vacuum Tubes

GLOW. A New Television Lamp, G. Gruskin. *Radio Industries*, vol. 5, no. 12, Apr. 1931, pp. 593 and 611-612, 1 fig. Development of radically improved type of point-source light by W. G. Taylor of Taylor Vacuum Products Co., does away with many limitations formerly ascribed to mechanical scanning; author has not yet been granted authority to release details of tube's construction or operating principles.

INDUSTRIAL APPLICATIONS. Vacuum Tubes In Industry, P. G. Weiller. *Radio Eng.*, vol. 11, no. 4, Apr. 1931, pp. 31-34, 4 figs. Important progress is being made in design and manufacture of mercury vapor rectifier tubes and tubes useful for automatic control of operating electric circuits; many opportunities await cooperative studies between tube engineers and engineers engaged in mechanical industries.

Voltage Regulators

The Application of the Induction Voltage Regulator, W. E. M. Ayres. *Instn. Elec. Engrs.—Preprint*, for mtg., Apr. 16, 1931, 11 pp., 21 figs. General application of induction regulators to feeder systems and distribution networks; problem of fully automatic control is dealt with and various methods of parallel working are discussed; point of application of regulator in system is considered from its practical and economic aspects.

Voltmeters

HARMONICS. Ein Oberwellen-Voltmeter (Harmonic Wave Voltmeter), R. Oetker. *Zeit. fuer Technische Physik*, vol. 12, no. 4, 1931, pp. 205-210, 10 figs. Description of simple and exact indicating instrument for effective value of harmonics of distorted voltage curve.

IONIC. The Ionic Wind Voltmeter and Thermo-Electrostatic Relay, W. M. Thornton and W. G. Thompson. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 412, Apr. 1931, pp. 533-544, 18 figs. Electric wind observed in neighborhood of highly charged point in air is caused by repulsion of ions which collide with uncharged molecules of air, thus giving to them velocity and, in effect; causing wind from point; instrument based on this action, termed "ionic wind voltmeter," was designed to indicate voltage of any system above few thousand volts by making earthed electrode part of hot-wire bridge.

Wave Filters

Extensions to the Theory and Design of Electric Wave-Filters, O. J. Zobel. *Bell System Tech. Jl.*, vol. 10, no. 2, Apr. 1931, pp. 285-341, 18 figs. Derivation and composition of wave-filter structures; designs of networks which simulate impedances of wave-filters, and of loaded lines; four Appendices contain new reactance and wave-filter frequency theorems, particular fixed transducer designs and certain equivalents.

Welding

ARC. Arc Welding in 1931, J. F. Lincoln. *West. Machy. World*, vol. 22, no. 2, Feb. 1931, pp. 65-66, 3 figs. Every year since war use of arc welding has gained greater momentum in practically every industry; regardless of economic outlook for 1931, it is safe to say that this process will be applied more widely and more frequently than in any preceding year; development of electrodes during past year for welding of various steel alloys will bring about much wider application of arc welding and in turn permit wider use of these alloy metals, particularly that of stainless steel and other corrosion-resisting metals.

Arc Welding Everdue, T. E. Jerabek. *Boiler Maker*, vol. 31, no. 3, Mar. 1931, pp. 68-69, 5 figs. Property of copper-silicon-manganese alloy, known as everdur; advantageous welding characteristics: procedure of metallic arc-welding process.

ARC-TESTING. Inspection Safeguards Quality, R. Kraus. *Welding Engr.*, vol. 16, no. 4, Apr. 1931, pp. 27-31, 14 figs. Inspection and testing methods of Westinghouse Co., with incorrect and correct sketches of welding procedure and layout of weld; testing of welders and dimensions of test specimens. Before Am. Soc. Testing Matls.

BOILER MANUFACTURE. New Technique in Welding is Result of Years of Scientific Research, K. B. Lydiard. *Pit and Quarry*, vol. 22, no. 2, Apr. 22, 1931, pp. 62-64, 11 figs. Results of investigations and laboratory experiments by research engineers of Babcock and Wilson; based on which technique was evolved which produces welds equal to or better than welded plate itself in tensile strength, shock resistance, ductility, and in ability to withstand repeated stresses; results obtained when this technique is used to weld carbon steel of firebox quality.

GAS PIPE LINES. Development and Results of Arc Welding of Gas Pipe Lines, H. C. Price. *Oil and Gas Jl.*, vol. 29, no. 48, Apr. 16, 1931, pp. 148 and 150. Review of development of electric welding of pipe lines, since 1928, with particular reference to long distance natural gas lines; operating practise; results; tests; advantages. Before Am. Gas Assn.

MACHINERY MANUFACTURE. Welded Construction Applied to Special Machinery, D. V. Waters. *Product Eng.*, vol. 2, no. 4, Apr. 1931, pp. 167-170, 6 figs. As result of development of acetylene and arc welding technique in recent years, welded steel construction in places where such construction was formerly deemed impracticable, is now used to good advantage; savings of both money and time in construction have resulted from use of welded steel; adaption of welding to special machine construction.

SHIPBUILDING. Electric Welding in the Construction of Sea-going Vessels, G. Wahl. *Shipbldg. and Mar. Engine Bldr.*, vol. 38, no. 251, Apr. 1931, pp. 321-326, 12 figs. Experimental ship constructed by Deutsche Werke in order to find new methods of electric welding applicable to shipbuilding and for training of welders; results of tests and conclusion. Before Instn. Engrs. and Shipbldrs. in Scotland.

VENTILATION DUCTS. Welded Fabrication of Ductwork, W. Spraragen. *Heat. and Vent.*, vol. 28, no. 3, Mar. 1931, pp 54-57, 9 figs. Preparation of material in repetitive production work; types of joints; expansion and contraction; stack welding.

Welding Machines

SPOT. The Dyer Bench Spot Welder. *Engineering*, vol. 131, no. 3401, Mar. 20, 1931, p. 408, 1 fig. Bench-type welder manufactured by Dyer Welding Machine Corp., Independence, Mo.; arrangement it is claimed, enables various parts to be joined together at place where they are assembled, thus saving time; welder is capable of making 1,000 welds per hr. on no. 16 gage sheet, variation in heat necessary for different metals being obtained through medium of three-position switch, which is fixed to housing containing transformer.

Industrial Notes

The Holophane Company, Inc., 342 Madison Avenue, New York, announces the appointment of A. D. Cameron as manager. Mr. Cameron was formerly active in the lighting field as manager of the lighting and supply division, central station department, General Electric Company, Schenectady, N. Y. Later he was vice-president of the Hall Electric Heating Company, of Philadelphia.

Ohio Brass Insulators Conform to New NEMA Standards.—To meet the new standards for switch and bus insulators decided upon at the May meeting of the National Electrical Manufacturers Association, the Ohio Brass Company, Mansfield, Ohio, announces a new line ranging in voltage ratings from 7.5 kv. to 69 kv. These new insulators, which simplify the construction, maintenance and repair problems of the user and make it much easier to coordinate line and station insulation, are now available for immediate shipment.

Miniature Relays.—A new line of miniature relays to be known as "Mid-Gett" is being made in eight contact arrangements by Struthers Dunn, Inc., 129 N. Juniper Street, Philadelphia. They are on standard bases and measure 1⅞ in. by 2¾ in., and follow in detail the design of regular type Dunco relays, having the three-legged stool principle of construction, form-wound, moisture-proof coils, renewable contacts, accessible terminals, with moulded bases. They operate on from 6 to 120 volts alternating current, or 24 volts direct current, depending upon the coil used.

New Vulcanized Fibre Insulation.—A new insulating material known as Dilecto K-4 is being produced by the Continental-Diamond Fibre Company, Newark, Del., manufacturers of Bakelite materials and vulcanized fibre. In addition to unusually high electrical insulating properties, Dilecto K-4 has high thermal insulating efficiency, is odorless and does not attract odors. It is finding a wide use as breaker strips on electric refrigerator cabinets. The material, which is highly resistant to alkali solutions and to water and moisture, will be made in sheets, rods and tubes, and can be machined readily.

Telegraph Code for the Electrical Industry.—A standard telegraph code for the electrical industry, sponsored by NEMA and other electrical associations, has been compiled under expert supervision for the use of the entire electrical field, not only for economy in communication, but to provide means for more frequent, accurate and comprehensive exchange of information of immediate necessity. According to the announcement it is the first instance of an entire industry uniting on a general code, and its cheap distribution is dependent upon the response to the pre-publication offer as detailed in the prospectus which is available upon application to the National Electrical Manufacturers Association, 420 Lexington Avenue, New York.

Trade Literature

Motors.—Bulletin 209, 32 pp. Describes type "D" heavy duty direct-current motors. Reliance Electric & Engineering Company, 1042 Ivanhoe Road, Cleveland.

Bridge-Stop Control.—Bulletin, 4 pp. Describes the new EC & M dynamic braking, bridge-stop control. This braking equipment is used on electrically operated overhead traveling cranes. The Electric Controller & Mfg. Company, 2700 East 79th Street, Cleveland.

Magnetic Clutches.—Bulletin, 24 pp., "Keeping Pace With Machine Design." Describes the construction, application and operation of C-H magnetic clutches, including a full description of the newly developed C-H duplex clutch. Cutler-Hammer, Inc., 12th & St. Paul Avenue, Milwaukee.

Circuit Breakers.—Bulletin 484, 4 pp. Describes type DR line oil circuit breakers, manual and electrical remote control, up to 2,000 amperes, 15,000 volts; 3,000 amperes, 7,500 volts; 60 cycle ratings, automatic or non-automatic. These breakers are designed for indoor service where space is an important factor. Condit Electrical Manufacturing Corporation, Boston.

Mercury Arc Rectifiers.—Bulletin 1907, 16 pp. Describes steel tank mercury arc rectifiers for converting alternating to direct current over wide ranges of both voltage and current. The most general use of this equipment is in supplying power for electric traction systems, although it has certain industrial applications. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Switchboards.—Bulletin 293, 18 pp. Describes Bull Dog "SaftoSwitch-Boards" type DF-30. These are of standardized sectional construction, totally steel enclosed, consisting of one or as many panels as desired, allowing changes or extensions, as requirements may demand. The scheme of standardization not only includes switches, but has been developed to cover air and oil circuit breakers, meters, etc. Bull Dog Electric Products Company, 7610 Jos. Campau Avenue, Detroit.

Hardness Testing Machine.—Bulletin, 24 pp. Describes the Firth Hardometer. This device extends the reliable Brinell method of hardness testing for use with thin materials, case hardened or nitrided surfaces, small parts, or any condition where a small indentation is necessary or desirable. The Firth hardometer differs from other instruments intended for the same purpose in that the diameter or diagonal of the impression is measured instead of the depth. Tinius Olsen Testing Machine Company, 500 No. 12th Street, Philadelphia.

Power Filter Unit.—Bulletin, 4 pp. Describes a new power filter unit which converts alternating current into pure, non-pulsating, humless direct current for use on telephones, sound-on-film, public address systems, inter-communication systems, clock and signal systems, magnetic chuck operation, elevator control and many other applications. The use of batteries in connection with the power filter unit is unnecessary, except where a standby source of direct current is required. Square D Company, 6060 Rivard Street, Detroit.

Potentiometer Pyrometers.—Catalog 1101, 48 pp. Describes a new line of potentiometer pyrometers having a broad application to industrial needs involving the measurement and control of temperatures, especially in the higher ranges. The introduction outlines the nature and field of the potentiometer principle as applied to pyrometers. The various types of these instruments include indicating, recording, controlling, multiple recording and multiple controlling. The Brown Instrument Company, Windrim & Wayne Streets, Philadelphia.

Lightning Arresters.—Bulletin 20365-A, 4 pp. Describes autovalve lightning arresters for the protection of railroad signal apparatus. Bulletin 20149-G, 4 pp., describes type SV autovalve lightning arresters for station use either indoors or outdoors, 1,000 to 220,000 volts. Bulletin 20013-K, 8 pp., describes type LV autovalve lightning arresters for the protection of distribution transformers. Bulletin 1737-F, 24 pp., is a comprehensive, illustrated publication describing autovalve arresters in general and the correct method of installation. Detailed engineering discussions, supplemented by drawings and diagrams, clarify many arrester problems. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Annual Technical Committee Reports To the Board of Directors

In accordance with Section 82 of the A. I. E. E. By-laws, the Technical Committees of the Institute have prepared the following reports for presentation at the Summer Convention.

In addition to a brief outline of its own activities, each committee gives a resume of the progress of the art within its field, so that collectively, these reports constitute an authoritative history of the developments in electrical engineering during the past year.

Table of Contents

Automatic Stations 542

Automatic Stations

ANNUAL REPORT OF THE COMMITTEE ON AUTOMATIC STATIONS*

CONSIDERABLE data on many phases of the automatic station art have been collected by subcommittees and are made part of this report, which is treated under headings as follows:

- Technical Papers
- Standards
- New Subjects
- Unfinished Business
- Fire Protection
- Wire Designations
- Research
- Operating Data
- Telemetering
- Bibliography

TECHNICAL PAPERS

The following papers are being presented under the auspices of the Committee at the Summer Convention, Asheville, N. C., 1931.

1. *A-C. Supervisory Control System.* By Othmar K. Marti.
2. *Supervisory Control for A-C. Electrified Railroads.* By C. P. West and H. C. Griffith.
3. *Automatic Combustion Control.* By C. H. Sanderson and E. B. Ricketts.
4. *Operating Experience with Automatic Stations.* By Garland Stamper and F. F. Ambuhl.
5. *Three Years' Operating Experience with Miniature Switchboard Supervisory Automatic Control.* By R. M. Stanley.

STANDARDS

Standards No. 26, Automatic Stations, has again been reviewed by the Committee. Recommendations for revisions in the list of device function numbers and in the table of minimum protection for power apparatus have been forwarded to the Standards Committee.

NEW SUBJECTS

Automatic combustion control and automatic alternating current networks have been studied this year by the Committee. A paper on Automatic Combustion Control, covering this subject extensively for the first time, is being presented at the annual convention.

UNFINISHED BUSINESS

Of the items listed last year, preliminary reports on Fire Protection, Load Dispatching and Wire Designations have been completed and are contained herein.

The following topics have been under consideration but no final reports have been rendered:

1. Economical Construction.
2. Noise Mitigation.
3. Automatic Alternating Current Networks.
4. General Telemetering.

SUBCOMMITTEE REPORTS

To the Subcommittees contributing the following reports generous acknowledgment is given. It is desired to make known that the efforts so prominently reflected in these reports are appreciated in full measure.

FIRE PROTECTION

Contributed by I. E. Moultrop and D. W. Taylor.

The methods of accomplishing suitable fire protection from the points of view of safety to personnel, safety to apparatus, and continuity of service have long been the subject of discussion and investigation by the electrical engineering profession. The size and importance of electrical installations make adequate fire protection a matter of utmost importance. The increasing use of automatically operated stations brings into prominence the special problems confronted by the designers of these usually unattended installations, which may in some instances be so far removed from the nearest aid in case of fire as to make automatic fire protection a corollary of automatic operation. It is the purpose of this report to point out some of these special problems.

When the subject of fire protection is considered, it is well to make a study of the causes of fires to obtain a perspective of the various elements entering into the problem. Consideration can then be given to design, and apparatus and material specifications, which will eliminate as much as possible the trouble at the source. Studies may be made to determine if oil circuit breakers have the necessary interrupting capacity; if all load carrying apparatus has the proper thermal capacity; if relay protection can be provided to clear short circuits before damage may occur, etc. Many apparatus characteristics, such as oil circuit breaker interrupting capacities, have been proven by tests so that greater reliability may be placed in their performance than was the case a few years ago.

Means to limit the fire to the vicinity of its source and prevent involving other apparatus in an attended or unattended substation, may take any one or more of three forms, *viz.:* automatic means of fire detection and alarm; structural means of fire isolation; and means of fire fighting, either manual or automatic.

---

*COMMITTEE ON AUTOMATIC STATIONS:

F. Zogbaum, Chairman,
Chester Lichtenberg, Secretary,
F. F. Ambuhl,
L. D. Bale,
C. W. Colvin,
A. M. Garrett,
Joseph Hellenthal,
O. A. Mayo,
I. E. Moultrop,
M. E. Reagan,
O. J. Rotty,
Garland Stamper,
D. W. Taylor,
L. J. Turley.

Automatic means of fire detection, as at present commercially developed, take the form of thermocouples and fusible links to convert the heat energy released by combustion into electrical energy, or of the more complicated apparatus working as a detector of the resultant smoke. Although these automatic means of fire detection have occasionally been installed in attended stations merely to alarm the operators, the recent mechanical improvement of the devices commercially obtainable for this service has resulted in considerable application of such devices in unattended stations to give alarm at some central attended installation and/or to operate fire-fighting equipment adjacent to the source of trouble. Unattended stations whose operations are reported to a central office through some means of supervisory control are particularly adapted for the installation of an alarm system between the station and the central office.

The second form of fire protection, structural means of fire isolation, is applied for the same reason and with equal effect in both attended and unattended stations. The large quantity of oil used in modern electrical apparatus makes fire isolation an important problem both indoors and outdoors. Generally, if possible, it is desirable to install large oil-filled apparatus outdoors and eliminate as much indoor oil-filled apparatus as is possible.

Indoors, apparatus of different types and different degrees of importance may be placed in different rooms, with fire doors between, either normally closed or closed by gravity upon the release of a fusible link. Some companies go so far as to install oil-immersed transformers in one room, large oil circuit breakers in a long narrow room with windows only at the ends, and oil-immersed voltage regulators in still another room; only the smaller breakers being installed in the same room with the switchboard and major bus structure. In connection with the location of windows, many stations are so arranged that any outdoor apparatus liable to catch fire, if installed adjacent to the building wall, are located at considerable distance from the nearest opening into the building. Another precaution taken as a means of indoor fire isolation comprises the use of cell doors and other trim made of treated wood or other fireproofed material. Current transformers, on which the relay protection is dependent, have been sometimes placed in separate compartments so they will not be involved in an arc from other equipment before they have actuated the tripping relays. Proper grounding of apparatus often lessens the chance of stray currents damaging other equipment during a short circuit. Elimination, as much as possible, of unprotected apparatus connected to the main bus is often desirable. Protection of apparatus, such as bus potential transformers, by means of resistance and fuses and careful isolation of bus arresters, should be considered.

Outdoors, transformers may be installed with fire walls between banks of two or three units or, if larger and more important transformers, between individual units. One company has recently adopted the policy, on large outdoor transformers, of eliminating the column-type oil gage from the conservator and of installing fuse-releasing gravity-closing valves on all connections between conservator and main tank. It is intended by this policy to prevent the spreading of possible transformer fires by the release of the large quantity of oil contained in the conservator, as sometimes happens through the cracking of the gage glass on the occurrence of fire in the immediately adjacent transformer and through the feeding out of burning oil from a rupture in the cover of a faulty transformer.

Both indoors and outdoors, fire isolation may be augmented by the installation of pits and drainage systems properly disposed with respect to oil-immersed transformers and regulators and oil circuit breakers.

The third form of fire protection, means of fighting the actual fire, divides naturally between the use of liquids and the use of gases. The most obvious liquid for this purpose is water, which is often piped to the end-bells of large rotating machinery and may be used elsewhere in connection with one of the commercial sprinkler systems; there is, however, considerable question as to the efficacy of water as a means of fighting oil fires. Other liquids take the form of special preparations, often generated on the premises at the time of fire, either by the mixture of two liquids or of water and a powder. Gaseous means are limited commercially to the use of carbon dioxide, which is heavier than oxygen and serves to smother the fire when applied in sufficient concentration; it is therefore particularly suitable in confined spaces where liquid might damage the apparatus and/or where the gases emanating from some of the commercial liquid preparations would be obnoxious. The efficacy of all these fire-fighting fluids may be considerably increased by the installation of permanent piping, designed to permit the direction of the fluid at the most advantageous point in case of fire. Whether or not the valves of this piping should be automatically operated depends not only upon the importance of the installation and the liability of a large fire, but also upon the proximity to a central attended installation and the attendant costs of automatic equipment for fire alarm as compared with the costs of automatic equipment for fire fighting in the unattended station.

It is believed that the art of fire protection is developing so rapidly, particularly in connection with unattended automatic stations, that no standards should be promulgated at this time by the American Institute of Electrical Engineers or others. It is thought that only by giving comparatively free rein can it be assured that progress will continue to be made in accordance with the best economic dictates.

The attached Appendix A is a preliminary attempt to classify for further investigation or study, I. the causes of fires, II. the spreading of fires, III. preventive measures, and IV. the extinguishing of fires.

Appendix A

I. Causes of Fires. II. Spreading of Fires. III. Preventive Measures. IV. Extinguishing of Fires.

I—Causes of Fires

A. Faulty Design
  1. Insufficient spacing.
  2. No allowance for temperature changes.
  3. Reduced clearances from distortion due to short circuits.
  4. Conductors or equipment improperly or insecurely supported.
  5. Weakness of mechanical structure or supports.
  6. Insufficient provision against heaving by frost, entrance of rain, or accumulation of sleet.
  7. Cannon construction (by cannon construction is meant the arrangement of barriers or compartments in such a manner as to direct an arc outward into other equipment or into operating aisles).

B. Faulty Equipment
  1. Improper design.
  2. Poor material.
  3. Defective materials or parts.
  4. Insufficient insulation, spacing of parts, strength or thermal capacity.
  5. Improper assembly.
  6. Improper and insufficient testing.
  7. Unnoticed failures as a result of testing.

C. Improper Application of Equipment
  1. Wrong material—moisture absorbing, subject to chemical change.
  2. Wrong apparatus—type, size, rating.

D. Aging of Apparatus and Material
  1. Deterioration of insulating material on conductors, supports, windings.
  2. Corrosion of metals from action of air, moisture, electrolysis.
  3. Effect of moisture, gases and corona in hastening deterioration.

E. Static Stresses
  1. Causing destruction of insulation.
  2. Collecting conducting material.

F. Magnetic Stresses
  1. Mechanical movement.
  2. Collecting conducting material.

G. Surges or Lightning
  1. Atmospheric conditions.
  2. Switching operations.
  3. Improper grounding.

H. Arcs (other than flashovers)
  1. Switching operations.
  2. Contactors.
  3. Commutators.

I. Exceeded Ratings
  1. Exceeded current rating, overload.
  2. Overvoltage.
  3. Exceeded temperature rating.
  4. Exceeded time.

J. Errors in Operation

K. Failure of Apparatus Containing Oil
  (This includes oil circuit breakers, oil switches, transformers, potheads, etc.)
  1. Insufficient amount of oil.
  2. Surplus amount of oil.
  3. Slopping of oil (mufflers, discharges).
  4. Dripping of oil on other apparatus.
  5. Lowering of oil level due to leaks, syphoning or intense cold.
  6. Freezing of oil.
  7. Carbonization of oil.
  8. Presence of moisture.
  9. Explosions due to arcs following short circuits.
  10. Poor contact.
  11. Puncture of bushing.
  12. Internal corona discharges.
  13. Internal earth fault.
  14. Internal short circuit.
  15. Phase interruptions due to mechanical failures.
  16. Short-circuited laminations.
  (Note: See other sections for failure of apparatus in general).

Exposure to External Attack
  1. Animals—birds, rats, nests, etc.
  2. Foreign material thrown on equipment—stones, kite strings, airplanes.

M. Dirty Apparatus
  1. Dirt from coal piles, or adjacent industries.
  2. Boring action of metallic slivers.
  3. Causing reduced radiation.
  4. Causing flashovers.

N. Spontaneous Combustion
  1. Oily waste or rags
  2. Coal.

O. Friction
  1. Lack of lubrication.
  2. Improper alinement.
  3. Dirt.

P. Condensation
  1. Unheated conditions.
  2. Temperature changes in conduits.
  3. Unventilated conditions.
  4. Wrong materials.

Q. Heating Equipment and Piping
  1. Failure of electrical heaters.
  2. Defective flues.
  3. Explosions of oil burners.
  4. Escaping steam or water from pipes.
  5. Broken fuel lines.

R. Carelessness
  1. Improper tagging or operation (disconnects, etc.).
  2. Cigarettes, matches.

S. Atmoshperic Conditions
  1. Flashovers due to fogs, especially salt water fogs.
  2. Sleet or wind.

T. Exterior Fires
  1. Adjacent buildings.
  2. Grass and forest fires.

II—Spreading of Fires

A. Inflammable Material in Apparatus.
  1. Insulating material in conductors, such as rubber and varnished cambric.
  2. Insulating supports or braces, such as wood.
  3. Oil or inflammable compounds.

B. Inflammable Material in Construction
  1. Wooden buildings, compartments, or structures.
  2. Forms used during construction.

C. Insufficient Segregation
  1. Insufficient barriers, compartments, cells or rooms.
  2. Insufficient spacing between types or classes of apparatus.
  3. Improper grouping of equipment, wiring, etc.
  4. Improper drainage of oil, etc.

D. Poor Housekeeping
  1. Rubbish during construction
  2. Accumulation of rubbish in operation.
  3. Storage of inflammable material.

E. Fanning Action of Ventilating Equipment.
F. Lack of fire Extinguishing Apparatus.
G. Failure to Announce Start of Fire, Smoke or Heat.

III—Preventive Measures

A. Use of fire-proof or fire-resisting material in construction.
B. Elimination of oil so far as possible.
C. Keeping premises and apparatus clean.
D. Segregation of apparatus.
E. Correct design or application.
F. Constant expert supervision.
G. Careful inspection before and during installation.
H. Periodic testing.

IV—Extinguishing of Fires

A. Detection.
B. Alarms.
C. Accessibility.
D. Automatic fire extinguishers—classification and suitability of each type.
E. Hand-operated extinguishers—classification and suitability of each type.
F. Drainage of burning oil.

WIRE DESIGNATIONS

Contributed by O. J. Rotty and M. E. Reagan.

The development of a uniform scheme of wire designations for station control wiring has been given some study with the idea that if a satisfactory scheme could be devised it should be offered for standardization.

The general use of such a scheme would produce uniform marking of control wiring at all stations regardless of whether the panels were wired by different manufacturers or by the user himself. This seems desirable for many reasons. The engineer laying out a new station or an extension to an old one would have to be familiar with only one scheme of wire designations and if the apparatus for a particular station was supplied by a number of manufacturers the wire designations would be alike for all the apparatus, resulting in simplification of interconnecting wires and common circuits. These points are also of importance to the construction or installation men, to the testing men, maintenance men, trouble shooters, etc.

At present there are many schemes in use, with each manufacturer and many utilities and engineering organizations having their own schemes all of which are different although some may have certain features in common. There seem to be many reasons why each scheme is preferred by its sponsor and why other schemes are objectionable. However, it is felt that a scheme can be devised which will fulfill practically all requirements and overcome the more important objections. The standard scheme must be of a general nature and must be applicable to all kinds of stations; *viz.*, railway, Edison, mining, hydro, a-c. distribution, and even steam plants.

There is a number of points in the designation of wires on which there is fairly general agreement. These are briefly as follows: 1. The scheme should be simple, easily understood and applied and with few special cases or exceptions; 2. it should be flexible so as to permit of additions or changes to the control without completely revising the existing designations; 3. it should provide the "tie-in" with or reference between the actual wire and the diagrams (either the wiring diagram, the schematic diagram, or both); 4. the wire designations should appear on the schematic (or elementary) diagram.

It also seems desirable that certain other ideas be worked into the standard scheme, which are briefly as follows: 1. The wire designation should be made up of as few digits as possible; 2. it should not be a complicated combination of letters and numbers; 3. it should preferably have some significance as to the apparatus or panel the wire connects to, although this appears to be difficult to devise and very likely an arbitrary scheme will be finally adopted; 4. operating and control buses and circuits of the nature of buses should be included in the standard scheme.

This subject has been taken up by this committee only recently and the time has been insufficient for the development of a finished scheme. However, it is felt that the work should be continued by the succeeding committee.

Several closely allied subjects have presented themselves for investigation but lack of time has prevented work upon them. They are: 1 Wire group or conduit designations or numbers, and 2, wire color codes. It is felt that these should also be given some study with a view to suggesting standards for them.

RESEARCH

Contributed by M. E. Reagan.

Research items to be studied and followed by the committee are divided under four main divisions. One object of investigation is to assemble data on operation while another object is to establish the trend of automatic expansion in operation. For instance, in the use of vacuum gas filled tubes in power and control systems, it will be the function of this committee to carefully record the various applications and keep experience charts showing the growth of usefulness and their performance.

The four general classifications are as follows:

I. Automatic Control of Rotating Machines (including mercury arc rectifiers).
  a. Synchronous converters.
  b. Motor-generator sets.
  c. Mercury-arc rectifiers.
  d. Hydro-electric generators.
  e. Frequency-changers.
  f. Synchronous condensers.
  g. Balancer sets.
  h. Battery chargers
    1. Automatic end cell switches.
II. Automatic Control of Static Machines.
  a. A-c. transformer substations.
  b. Periodic reclosing feeders.
  c. Static condensers.
III. Network Protectors.
IV. Supervisory Control.
  a. Terminal apparatus.
  b. Channels.
    1. Fused lines.
    2. Private.
    3. Carrier, etc

Suggested Items.
  a. Curve of total installations by years.
  b. Curve of total kva. by years.
  c. Curve of per cent automatic to manual installation by years.
  d. Curve showing rehabilitation of old units for automatic service.
  e. Curve showing per cent availability by years.
  f. Data on primary causes of outages, such as
    1. Line trouble.
    2. Main apparatus trouble.
    3. Control trouble.
    4. Due to testers or maintenance man.
  g. Performance data on fuses in control circuits.
  h. Ventilation as it affects "sweating" of apparatus.
  i. General field testing of equipment expand last year's report.
  j. Data on vacuum tube applications of all types in control work.

TELEMETERING IN CONNECTION WITH LOAD DISPATCHING

Contributed by A. M. Garrett and J. J. Samson.

In order that electrical systems, particularly those of the public utility and traction companies, function with the highest degree of service standard and efficiency, it is necessary that the control of certain system operations be centralized.

Such operating knowledge and duties as restoration of the service to normal during or following a case of system trouble; the interchange of energy between systems or parts of the same system; switching in and out of service of generating station or substation units in accordance with load demands; the load quantities existing in different parts of the system; the maintenance of proper voltage, frequency, temperature of equipment; adjusting the system to take care of construction work in connection with system extensions, maintenance and repairs, are some of the functions that must come under the guidance of this group.

The majority of these functions is under the control of the load dispatcher or system operator who depends upon his knowledge of the operating condition of the system through the forces which actually operate it. This information comes to him in the nature of a periodic check, generally by telephone.

In recent years as the system developed through growth and expansion, and in some instances through combination, the problems associated with the handling of these systems become more involved, so that the need for quicker and more accurate information as to the operating status of the system became apparent. In order to handle the situation intelligently, a continuous record or "running account" so to speak was needed instead of a periodic sampling of conditions. To meet these requirements telemetering or remote indication equipment has been developed and placed in service in many systems in this country in the past five years. To take care of these problems under the old method would mean quite a material increase in the load dispatchers' force.

Telemetering is a means of transmitting to a central control point over a communicating circuit or special conductors, information necessary for the operation of the equipment, station or system. This may be electrical quantities (volts, amperes, watts, power factor), temperature, position of breakers, regulators, or any other information that it may be desired to obtain from the system.

It consists essentially of a transmitter at the remote end connected to the equipment from which information is desired, a receiver at the control end and the connecting circuit. The quantity of energy to be measured or position of equipment to be indicated is converted to a voltage and current (suitable for telephone cable) whose value is proportional and is transmitted to the receiver which is calibrated to record the information.

With a view to determining the trend of telemetering devices and methods, the committee decided that a survey in the form of a questionnaire should be made of those companies now operating this class of equipment. The questionnaire covered the following points:

1. What of the following do you use telemetering for?
   Totalizing load.
   Current and voltage conditions.
   Temperature of equipment.
   Position of switch gear.
   Tap changer and regulator positions.
   Uses other than above.
2. State briefly the type of system and the principles of operation.
3. What channels are used?
   Telephone lines.
   Transmission lines.
   Special conductors.
   State approximate distances of transmission.
4. Is this system of aid in load dispatching?
   In what manner?
5. What criticism do you have of telemetering?
6. What, in your opinion, is the trend of development?

The term "load dispatching" is understood to cover broadly the function of load control and switching operation which is dependent upon telemetering information.

This survey has just been completed and a total of 35 companies canvassed. The following information has been compiled:

Under uses or application we found approximately 40 per cent of the companies use the equipment for determination of current and voltage conditions, while 22 per cent of the installations were for totalizing load and 18 per cent were for position indication of equipment.

Under types used, there seems to be a general use of direct current either in the form of balanced current or rectified current.

As the connecting circuit between the remote end and the receiving end, about 30 per cent used active telephone circuits, while the remaining 60 per cent used special conductors. The distance of transmission varies from 500 feet to 15 miles with no special average.

In answer to the direct question of whether the system was an aid in load dispatching, 60 per cent stated that it was, while the rest of the replies gave no opinion or indicated lack of experience due to the short time the equipment had been in service.

In reply to the inquiry on criticism of the equipment, the survey showed little or no adverse expression. One point emphasized was the lack of high speed response with accuracy comparable to the usual line of switchboard indicating instruments. There is a tendency where high speed is desired to sacrifice somewhat the matter of accuracy. Another criticism was on the cost basis, the installed cost of the equipment running into "considerable money." Especially is this true where special conductors are required over long transmitting distances.

Improvements toward simplification of the present complicated equipment, as means to greater reliability, was offered as one criticism.

On trend of development, practically all replies indicated a favorable reaction to future development, especially where extension to the system was in prospect. This applies particularly to the situation where interconnection is concerned. One reply mentioned there would be no future development for telemetering in this company as the type of distribution was being changed to an a-c. network whereby the substation would be eliminated.

In general, it can be stated that telemetering has established itself, and with extension of load control and switching operations made necessary through an increase in the size of systems, in interconnection between systems, and constantly increasing number of unattended stations, telemetering is proving a distinct aid in the solution of those problems of handling and operating an electric system.

Communication

ANNUAL REPORT OF THE COMMITTEE ON COMMUNICATION*

IN accordance with the usual practise, this committee submits herewith a brief review of the developments during 1930 in electrical communication.

TELEPHONE SERVICE IMPROVEMENTS

Telephone service was improved during the year by the application of new developments and methods and improved maintenance. The average time to complete toll calls was lowered by 12 seconds to an average of one minute. Improved maintenance methods have reduced the frequency of troubles affecting subscribers' lines so that a trouble now occurs on the average but once in 22 months, a reduction in trouble frequency of about 11 per cent as compared with 1929.

Steady advancement in the quality of speech transmission was accomplished. On the longer haul toll business, unsatisfactory transmission conditions were experienced on only 1.5 per cent of the messages, compared with 1.7 per cent in 1929. One of the important factors contributing to this improvement was the institution of a more effective method for controlling the amplification of speech on toll calls involving two or more long circuits. An improved general plan for the design and rearrangement of plant to handle calls between remote points not connected by direct circuits was adopted. Under this plan, the number of intermediate switches is minimized with a consequent improvement in speed, accuracy, directness of routing, and transmission. A paper describing this plan, by Mr. H. S. Osborne, was presented at the 1930 Summer Convention. (A. I. E. E. TRANS., October 1930.)

SUBSCRIBER'S EQUIPMENT AND SERVICES

During 1930 the number of hand telephone sets in service increased to approximately 2,000,000 as against about 1,000,000 at the beginning of the year. The development of a type of hand set which would meet the electric and acoustic requirements of telephone practise in this country has involved the solution of difficult technical problems. These problems have been concerned primarily with the suppression of singing, for which the hand set has a tendency because of the rigid connection of the transmitter and receiver, and with the efficient operation of the transmitter in a wide range of angular positions. These difficulties have been successfully overcome through the application of a large amount of scientific work in the design of the hand set handle, the transmitting and receiving elements, and the electrical circuit connecting them. These achievements have made it possible to use the hand set without any sacrifice in performance as compared with the desk stand set.

For subscribers requiring a large number of attendants to take messages or orders, there has been made available an automatic call distributing arrangement associated with a simple type of attendant's position, whereby calls are immediately connected to idle attendants or, if none are available, are held and subsequently connected in the order in which they arrived.

A new type of private branch exchange suitable for larger residences and business offices of moderate size was made available during the year. No operator or attendant is required. Calls may be originated, answered, and transferred from any of the telephones. Intercommunicating calls are made by means of the dial. Complete privacy for both outside and intercommunicating connections is provided.

While arrangements have been available for some time for private branch exchanges whereby a number of telephones could be connected together simultaneously in a conference connection, these arrangements have been extended during the past year so as to enable the interconnection of a larger number of stations and to include more than one trunk circuit out of the private branch exchange.

CENTRAL OFFICE SYSTEMS AND APPARATUS

During 1930 there was an increase of about 1,000,000 dial stations, bringing the total to approximately 5,565,000, or more than one-fourth of the total number of stations in this country. Besides the conversion to dial of additional portions of large cities, increasing use has been made of dial equipment in small communities where services requiring the assistance of operators can economically be handled from near-by centers.

Further extensions have been made in the mechanical tandem facilities used primarily for service between the larger areas and neighboring suburban points. Arrangements are now in service for automatically inserting voice repeaters when required on calls between the more distant points. Facilities are also included for completing calls to a variety of types of offices, either mechanically or by key sets at call distributing tandem positions. An installation of call announcer apparatus, described in last year's report, has been made in New York. The mechanical tandem also includes a trouble recorder which provides a continuous count of calls affected by various classes of irregularities and prints, by means of a teletypewriter, a complete record of the channels and equipment used by such calls.

---

*COMMITTEE ON COMMUNICATION:

G. A. Kositzky, Chairman,
H. M. Bascom,
G. R. Benjamin,
B. K. Boyce,
A. F. Brooks,
W. H. Capen,
J. L. Clarke,
R. N. Conwell,
C. F. Craig,
B. R. Cummings,
H. W. Drake,
R. D. Evans,

J. L. Niesse,
H. S. Osborne,
F. A. Raymond,
H. A. Shepard,
H. S. Sheppard,
A. N. Symes,
H. M. Turner,
F. A. Wolff.

The panel system has been provided with a new type of equipment known as the decoder for translating the digits dialed by the subscriber into the electrical information required for routing the call to various types of offices. Panel equipment in certain areas is also being arranged to permit subscribers to dial calls directly to distant zones which previously required the supervision of an operator because of the additional charges involved. The equipment is arranged to determine the number of message units corresponding to the charge to the zone in which the call terminates and to cause a corresponding number of operations of the message register.

Time announcement systems for use in the larger areas have been modified by the addition of facilities for the distribution of announcements over a trunk network, equipped with repeaters to insure adequate volume and quality, so that one operator may furnish time announcements for a network of offices.

An improved low-speed interrupter, utilizing mercury make and break contacts, has been developed for use in giving flashing signals to operators and in timing sequence operations. For producing tones used as signals to operators and subscribers, there has been developed an alternator which enables close control of the frequency, magnitude, and harmonic content of the tones. The field windings and the tone output windings of this alternator are formed on the stator, and the tone is produced by an unwound, toothed rotor which varies the magnetic flux in the tone windings.

Privacy apparatus was put into service during the year on nearly all of the intercontinental radio telephone circuits operated out of this country. By means of this apparatus the radio waves transmitting conversations are so modified in their characteristics that if listened to with an ordinary radio set, speech is not intelligible. At the receiving end this process is reversed and intelligible speech restored. While this does not guarantee complete secrecy, it does furnish a considerable degree of privacy and represents an important step in advance.

Another important toll equipment development was a new type of toll switchboard in which the use of smaller jacks makes possible a substantial increase in the number of trunks and toll lines appearing at each toll operator's position. Tandem positions are also provided through which an operator may secure access to any circuit not appearing in the toll line multiple at her position.

OUTSIDE PLANT CONSTRUCTION AND METHODS

To facilitate the placing of tape armored toll telephone cables, a method has been developed whereby the trenching, laying of the cable, and the filling of the trench are simultaneously accomplished in one operation. This method utilizes a tractor behind which are pulled the trailer supporting the cable reel, the plow, and the drag which fills in the trench. From the reel, the cable is threaded through a pipe which leads it to the trench at a point directly in back of the plow. Under ordinary conditions it has been practicable, on the average, to lay more than one mile of cable per day with one outfit, using this method.

A new method which utilizes a single tube sleeve has been developed for making joints in aerial line wire. A hand operated rolling tool compresses the sleeve onto the wire in such a way as to provide a joint with no greater electrical resistance than a corresponding length of line wire and with a tensile strength at least equal to that of the wire. This new joint is expected to avert the electrical troubles now experienced with open-wire joints of the twisted sleeve type.

An important step has been taken by the communication interests cooperating with other pole using utilities, and others connected with the pole industry, in arriving at uniform classification dimensions for wood poles of southern yellow pine, western red cedar, northern white cedar, and chestnut. This work was carried on by the American Standards Association. Standard fiber strengths lb. per sq. in. have been established as follows: 7,400 for southern yellow pine, 5,600 for western red cedar, 3,600 for northern white cedar, and 6,000 for chestnut. These values have been accepted and made American Standards.

Under the new classification, a pole of a given class designation will have approximately the same breaking load regardless of pole length and species of timber. The adoption of the new grouping by all users of wood poles is expected to result in economies in the production and stocking of poles. The problems introduced by joint use will also be simplified as both parties to the joint use agreement will be using the same classification, whereas in the past this was seldom the case. Cost comparisons between the various species can be more easily made under the new classifications as prices may be directly compared class for class, whereas under the old tables calculations had to be made to determine the class of equivalent poles of other species of timber.

LONG DISTANCE TOLL CABLES

About 5,000 miles of cable for toll use were added to the telephone system of this country in 1930, bringing the total toll cable mileage to approximately 24,000 miles. Including the toll cable network on the Pacific Coast, which is connected with the toll cable network of the rest of the country by several individual and widely separated open-wire toll routes, there are now 129 out of 176 cities of the country having populations of 50,000 or more connected directly into the toll cable network. The fourth telephone cable between Key West and Havana was completed in January 1931. The new cable is non-loaded and employs the recently developed paragutta insulation. It is equipped with carrier telephone apparatus which now provides three telephone message circuits, as well as one d-c. telegraph circuit. Provision has been made for the addition of other telephone circuits when needed. The telephone facilities now afforded by the single new cable are equal to those furnished by the three older cables in total. This gain in efficiency is brought about by improvements in the art of cable construction, including employment of paragutta, as well as advances in the application of carrier methods using high frequencies for multiplexing.

About 35,000 miles of telephone circuit are now being regularly utilized for radio program transmission service and almost 200 radio broadcasting stations receive programs from these chains of wire circuits. Heretofore practically all of this service has been furnished by means of open wires using voice-frequency channels. However, a new type of circuit for toll cables has recently been developed which permits of transmission over long distances without material distortion of a frequency range from 50 to 8,000 cycles, at the same time transmitting a volume range of about 40 db. (energy ratio 10,000 to 1). These characteristics are desirable for the satisfactory transmission of music where the frequency and volume range requirements are much greater than in the case of speech. This new type of cable circuit is loaded at 3,000-ft. intervals and special repeaters are placed at approximately 50-mile intervals. Associated with each repeater is an attenuation equalizer and a delay equalizer, which correct for the attenuation and delay differences at different frequencies. A paper on this subject, by Messrs. A. B. Clark and C. W. Green, was presented at the 1930 Summer Convention (A. I. E. E. TRANS., October 1930, p. 1514.)

CARRIER TELEPHONE AND TELEGRAPH

During 1930 about 160,000 channel miles of carrier telephone facilities and 400,000 channel miles of carrier telegraph facilities were installed in the United States. Recent improvements of carrier circuits involve improved transposition arrangements and the introduction of 8-in. spacing of wires in place of the 12-in. spacing. This latter development permits an increase in the number of facilities obtainable from a given number of wires on a pole line.

The operation of voice-frequency carrier telegraph over the channels of high-frequency carrier telephone systems has been successfully applied. For example, each of the three two-way channels of a carrier telephone system has been filled with 12 carrier telegraph channels. Such a pair of wires accommodates a duplex d-c. telegraph circuit, an ordinary two-way message telephone circuit and 36 duplex carrier telegraph channels which if multiplexed would afford means for the transmission of about 7,500 words per minute for the telegraph facilities alone.

A paper by Mr. E. I. Green, discussing the transmission characteristics of open-wire telephone lines, and a paper by Mr. L. T. Wilson, discussing telephone line insulators, were presented at the 1930 Summer Convention. (A. I. E. E. TRANS., October 1930.)

INTERCONTINENTAL TELEPHONY

Most notable of the advances made during 1930 in the intercontinental telephone field was the opening on April 3 of service to South America. This service is provided by a short-wave radio circuit operating between the transmitting and receiving stations at Lawrenceville and Netcong, New Jersey, and corresponding stations near Buenos Aires, Argentina. The ratio portion of this circuit is 5,300 miles in length and it is therefore, the longest circuit now operating from the North American continent. The transmission characteristics of this circuit are, however, somewhat better than those of the short-wave circuits between the United States and England, due principally to the fact that the transmission path of the South American circuit is further removed than is that of the North Atlantic circuit from the polar regions and the adverse influences of magnetic storms. Furthermore, the South American circuit, running nearly along the meridian, experiences a more uniform condition as to daylight or darkness. As a result of these factors, extreme variations in transmission, which form an important problem on the east- and west-bound radio circuits, are materially reduced on this circuit.

At Buenos Aires the radio circuit connects with wire and cable circuits to more than 325,000 telephones in the Argentine Republic, Chile, and Uruguay, including the cities of Santiago and Montevideo.

Another feature of interest during the year was the establishment of radio communication between the United States and Australia by way of London. At London the transatlantic circuits are connected to a London-Sydney short-wave radio circuit, which at Sydney connects in turn with the wire network of the Australian Telephone Administration. This combined circuit is approximately 14,000 miles in length.

Four papers, discussing transoceanic telephone service in its various aspects, were presented at the 1930 Winter Convention by Messrs. T. G. Miller, Ralph Bown, A. A. Oswald, and F. A. Cowan.

By the end of 1930, many parts of the world had been linked together by radio-telephone circuits in addition to those mentioned above. Most of these circuits have one end in Europe, far ends in such distant places as Brazil, Argentina, Australia, New Zealand, Siam, Indo-China, Java, and Algiers. Not all of these circuits are yet connected with the telephone systems at their terminals, and they do not all, therefore, possess to the same degree the universal accessibility and utility of those radiating from North America.

SHIP-TO-SHORE RADIO-TELEPHONE SYSTEMS

A novel type of ship-to-shore service was inaugurated in the middle of the year through the equipment with radio-telephone apparatus of a New York City fire-boat. This equipment is arranged to enable continuous two-way telephone service between the master of the fire-boat and his land headquarters when the boat is under way. By means of this close communication, it has been possible to coordinate the efforts of the land and marine fire forces more effectively. As a result of the demand for telephone service of this kind in important harbors, both for harbor craft and ocean-going vessels, plans have been made for opening to such service in 1931, radio-telephone stations at Los Angeles, San Francisco, Puget Sound, and New York.

Commercial telephone service between ships at sea and the telephone system of the United States was extended during 1930 so that this service is now available to five ships: the Leviathan, Majestic, Homeric, Olympic, and Belgenland. Several organizations are involved in the provision of this service: the International Marine Radio Company, a subsidiary of the International Telephone and Telegraph Company, the Marconi Company, and the American Telephone and Telegraph Company. The shore stations are operated by the American Telephone and Telegraph Company on this side and by the British Post Office on the European side. During 1930, construction of a new land station at Ocean Gate, New Jersey, to care for transmission from shore to ship was completed. As in all radio-telephone transmitting stations, the antennas at this new station have a marked directional characteristic, the transmitted waves in this case being directed so as to traverse the North Atlantic shipping lanes. Four different wavelengths are used for transmission, ranging between 17.5 and 63 meters. Generally speaking, reliable transmission has been obtainable at distances from New York up to about 1,000 miles, corresponding with two days' sail. While satisfactory talks have been made at distances of 2,500 miles or greater, transmission at such distances has not been uniformly good.

A paper by Messrs. William Wilson and Lloyd Espenschied, discussing radio-telephone service to ships at sea was presented at the Northeastern District Meeting in May 1930.

TELEGRAPHY

During 1930 all Western Union tickers handling New York Stock Exchange service in the United States were converted to the high-speed type. This permitted increasing the output of stock quotations from 300 to 500 characters per minute. In the field of telegraphic distribution of quotations and other market information, many improvements in apparatus and methods of operation were developed and applied during the year which resulted in a reduction of manual handling, greater output and extended operation into territory not heretofore reached, including quotation service to Cuba.

There has been a considerable expansion during the past year in the use of automatic quotation boards for electrically indicating market prices and this service has been extended to a number of other cities in addition to New York, where the first boards were installed.

Numerous additional installations have been made of concentration equipment for printing telegraph circuits. A description of the apparatus used for this purpose is contained in the paper entitled *A Printing Telegraph Concentrator* presented by Mr. W. B. Blanton at the Winter Convention in January 1931.

The Western Union Telegraph Company has developed a method whereby channels of a multiplex system circuit may be automatically repeated and extended individually over single wires by means of simplex printers to offices. Circuits from several offices using simplex printers may be grouped at a central point and combined into a multiplex circuit to a distant central office. This system will give many small offices direct outlets to the large centers which could not have been economically provided with previous methods.

During the year there was a marked increase in the tendency to employ, in place of direct current telegraph to outlying points superposed on telephone circuits, a method of operation which is called "two-path polar operation." This involves the use of independent one-way polar circuits for the two directions and affords improved service with a lower maintenance cost as compared to the usual polar duplex method.

Several methods of measuring the quality of telegraph transmission have been developed. One form of apparatus which has been found very effective both in the laboratory and the field was described by Mr. F. B. Bramhall in a paper entitled *Telegraph Transmission Testing Machine*, presented at the 1931 Winter Convention.

A paper describing various technical features in connection with the submarine high-speed duplex telegraph cable between Bay Roberts, Newfoundland and Horta, Azores was presented at the Winter Convention in 1931 by Messrs. J. W. Milnor and G. A. Randall. At the same convention, Mr. Milnor presented a paper on the influence of interference in submarine cables.

In addition to the statewide police teletypewriter systems in Connecticut and Pennsylvania, an extensive system of about 30 stations was installed last year in New Jersey for the New Jersey State Police. There is an increasing number of large city police networks, such as those of New York City, Boston, Buffalo, and St. Louis. The United States Coast Guard also has such a system in use along the New England Coast.

Progress has been made in the development of switchboards for teletypewriter service to permit the interconnection of these machines in a manner similar to that by which telephone instruments are interconnected.

A new type of belt conveyer has been developed by the Western Union Telegraph Company for carrying telegrams between the various parts of the central office. In this conveyer messages are carried along between a steel channel and a moving flat belt about 1¾ in. wide, the motion of the messages being due to their sliding along the steel channel with practically no friction while adhering quite firmly to the belt. The messages can be taken around vertical or horizontal turns as well as through vertical and horizontal twists.

MUNICIPAL AND PROTECTIVE SIGNALING

There has been a steady increase in the use of electrical traffic signals. In the larger cities there have been several installations of flexible progressive systems, while in smaller places and in outlying sections of the larger cities, the detached intersection type of signal is still largely used. For important intersections and through traffic highways, vehicle controlled signals have been fairly successful but are expensive to install and maintain, as compared with the predetermined period signals. Vehicle control of signals obtained otherwise than by switches imbedded in the street surface, such as light beam control, has been tried out.

There has been a considerable use of electrical caution flashers in place of earlier types employing compressed gas, and practically all new installations are electrical. More illuminated caution signs are being installed and cheaper methods of illumination than by the neon tube method are being investigated

An important development of the past year concerning municipal fire alarms, has been the production of signal boxes and central office control apparatus, making effective use of ground return to send in alarms at such times as the circuit is in abnormal condition. Previous attempts to accomplish this introduced some abnormal condition on an otherwise normal circuit. This defect has now been practically overcome, and signal boxes have been developed that will operate in the usual manner on a normal circuit while at the same time they will transmit signals over a grounded, short-circuited or broken circuit without the necessity of making any temporary alterations at the signal box. While this development is too recent to be able to judge of its effects, it may permit of more leeway in circuit construction than is now considered safe, such as the installation of both sides of a circuit in the same aerial cable. The importance of this improvement may be estimated when it is considered that fires often occur at times when circuit conditions are apt to be disturbed by storm, explosion, or accident.

The use of single battery with trickle charger in place of duplicate batteries charged alternately by motor-generators is increasing with consequent increase in battery life.

The use of rectifiers and floating batteries or of transformers and a-c. circuits in connection with institutional fire alarms has progressed to such an extent that practically all new installations make use of public electric supply for the operating current in preference to primary batteries or to storage batteries charged from motor-generators. The practise of connecting automatic sprinkler alarm valves to municipal fire alarm boxes so that an alarm will be sounded automatically for any appreciable flow of water, has spread.

Experiments have been made on improved flash-light mechanisms for calling patrolmen to signal boxes. One such system has been installed lately in Boston. This permits any citizen desiring to call a policeman to operate an exposed lever which starts the flash-lights blinking the number of the signal box from which the call is made.

TELEVISION

Further advance was made in television as an accessory of telephone conversations by the development of means whereby two people at a distance are enabled both to converse and to see one another as if seated face to face in the same room. One of the interesting problems encountered in this development was that of sufficiently illuminating the faces of the parties engaged so that their images could be transmitted without, at the same time, dazzling their eyes to such an extent that they would be unable to see before them the image of the other party. This difficulty is met by employing blue light for scanning the faces of the parties. While the eyes are relatively insensitive to this color, the photoelectric cells used to pick up the light reflected from the face and generate the television signals are highly sensitive to it. Concealed microphones and loud speakers connected by four-wire telephone circuits are used in place of conventional telephone instruments to provide the talking portion of the system. The problem of operating a loud speaker and a sensitive microphone in the same small booth in such a manner that a self-sustaining singing circuit would not be created has been solved by specially treating the walls of the booth to prevent the reflection of sounds into the transmitter and by so locating both transmitter and loud speaker that the transfer of sound between them is minimized. While the experimental system is only two miles long, the television apparatus will function satisfactorily over distances of hundreds of miles when connected by suitable circuits as was shown by the one-way demonstration between New York and Washington.

Three papers dealing with television, by Messrs. H. E. Ives, F. Gray, M. W. Baldwin, H. M. Stoller, D. G. Blattner, and L. G. Bostwick, were presented at the 1930 Summer Convention. (A. I. E. E. TRANS., Oct. 1930.)

AIRPLANE RADIO-TELEPHONY

Development of telephone communication with airplanes continues to progress, and it has been found to be of very great importance for communication between transport planes and ground stations. Two-way radio-telephone apparatus for communication between planes and ground has been developed and supplied for equipping a comparatively large number of planes. The value of such equipment may be indicated by the fact that legislation provides for increased revenue to air mail contractors flying planes equipped for two-way radio communication

Two papers on this subject were presented during the year, one by Mr. R. H. Freeman at the Pacific Coast Convention, the other by Mr. Eugene Sibley at the Middle Eastern District Meeting in October.

SYNCHRONIZING RADIO BROADCASTING STATIONS

There has been considerable experimental work carried on during the past year by the prominent radio organizations along the line of synchronizing broadcasting stations so that the same radio program may be broadcast from different stations operating at the same frequency. Best results are obtained only with a high degree of synchronism between the carrier frequencies of the different radio stations. In certain of the more successful experiments the control of the radio station frequencies has been carried out by sending over wire circuits standard frequencies of 4,000 or 5,000 cycles which, at the radio stations, are stepped up and used either directly to provide the radio carrier or indirectly to control the frequency of a local oscillator. While it is evident from the tests which were made that line circuits can be used very satisfactorily for transmitting control frequencies, certain requirements are imposed on the radio station frequency step-up equipment to iron out minor line fluctuations, which are, of course, greatly exaggerated when the frequency is raised from the relatively low frequency transmitted over the lines to the radio frequency of from 500 to 1,000 kilocycles.

STANDARDIZATION OF RADIO TERMS

During the past two years the Standardization Committee of the Institute of Radio Engineers has had under way a complete revision of definitions of terms, abbreviations, symbols, and methods of measurements and tests. A preliminary report of this work was issued in December, 1930.

FOREIGN COMMUNICATION MATTERS OF INTEREST

During the year international service was extended in Central America by the interconnection of Guatemala and El Salvador. In Mexico the subscribers of a second large network were given access to the United States and all points reached therefrom.

Conference toll service or multiple telephone service was established in the Netherlands. By means of this system from three to six subscribers in the same or different cities may be interconnected at the same time so that any one of the subscribers may be heard by all of the others.

Picture transmission service was extended in a number of countries, particularly in Japan.

In Europe the toll cable network was increased during the year by 6,000 to 8,000 kilometers. Two additional submarine cables were placed across the English Channel and one was placed between Sweden and Germany.

A complete rotary automatic exchange system was installed in Vatican City and connections were established with the international network.

Direct dialing over long distance telephone lines was successfully demonstrated in Europe and installations were made in several countries. Toll dialing has been employed in the United States to a limited extent for a number of years.

Transatlantic radio-telephone service was extended to include a number of new countries in Europe and to reach additional points in countries to which service had previously been given. Connections to points within the Antarctic Circle became possible for the first time when the service was extended in South America to include a number of additional cities in Argentina and Chile.

During the year the International Telephone and Telegraph Corporation, in cooperation with the government administrations concerned, opened direct radio-telephone links connecting Buenos Aires with Paris, Berlin, and London. These additional links between South America and Europe not only decrease the use of long land lines formerly required to serve points distant from the radio terminal, but greatly increase the reliability of the international connections as a whole. When, because of atmospheric disturbances or for other reasons, one link is unable to give commercial service, the traffic may be routed over one of the other links. The question of allotting the traffic over the different circuits and adjusting rates so that the rate between two points will not depend upon the routing of the call has been by no means a simple one, but with the cooperation of the various government administrations much progress has been made.

Commercial service was made available between telephone subscribers in Chile, Uruguay, and Argentina, and subscribers in Belgium, Denmark, Switzerland, Austria, Lithuania, Poland, Esthonia, Norway, Sweden, Czechoslovakia, and Jugoslavia through one or another of the four direct links from Buenos Aires which, of course, also serve Spain, France, Germany, and Great Britain.

Commercial telephone service was opened to some of the Canadian National Railway express trains and equipment for the reception of broadcast programs on moving trains was provided in a number of countries, including Jugoslavia, Italy, and Austria.

During the year technical development work continued to prepare for improvements in existing apparatus and methods as well as to explore new fields, such as signaling and dialing over radio-telephone circuits, and the use of the so-called ultra short waves, those of under five meters.

COOPERATION BETWEEN WIRE USING COMPANIES

The many problems arising in coordinating the wire plants of the power and telephone companies led to the formation of the Joint General Committee of the National Electric Light Association and Bell Telephone System in 1921. Since that time an extensive program of investigation has been in progress and many important results of this work were published in 1930 as Volume 1 of Engineering Reports of the Joint Subcommittee on Development and Research. A review of the work of this subcommittee was given in a group of four papers presented at the 1931 Winter Convention as a symposium on the coordination of power and telephone plants.

During the last two or three years three other Joint General Committees have been organized with the general objective of working out methods of procedure for the coordination of wire plants. These are the Joint General Committee of the Western Union Telegraph Company and the National Electrical Light Association, the Joint General Committee of the American Railway Association and National Electric Light Association and the Joint General Committee of the American Railway Association and the Bell Telephone System. These committees are proceeding with the formation of the fundamental bases of procedure for the cooperative handling of mutual problems between the utilities concerned and the carrying out of such development and research work as appears to be necessary in connection with the problems involved.

APPLICATIONS OF PROBABILITY THEORY IN TELEPHONE PRACTISE

The importance of the probability theory and the related theory of statistics in telephone practise are, in a general way, well known by the engineering profession. However, a short résumé of the matter together with a brief statement of additional applications made during the last year may be welcome.

The oldest and best known application of the theory in the art of communication is its use in the determination of the loads which can be placed on various manual and dial trunking arrangements in order that efficient service be rendered. Unbalance effects on loaded circuits and other transmission lines of periodic structure also give rise to linear and other types of error function problems for the solution of which recourse to probability theory must be had.

The scheduling of adequate sampling plans for determining the quality of telephone equipment at various stages of its manufacture, after delivery to the operating companies and after installation, make heavy demands on probability and statistical theory. Within the last year extensive sampling schedules have been made for determining the extent to which the human factor in the telephone business is performing its assigned functions. For example, sampling theory is now being applied with reference to the performance of the repair clerk and test desk man, the quality of work done by installers and repairmen, the quality of subscribers' contacts in commercial offices and the quality of directory printing and delivery service.

Electric Welding

ANNUAL REPORT OF THE COMMITTEE ON ELECTRIC WELDING*

THIS report consists of two sections; the first dealing with the Organization and Policies, and the second with the Progress of the Art.

I. ORGANIZATION AND POLICIES

During its first three years, this newly created committee has gradually extended its field of action until the field overlapped that of various technical committees of the American Welding Society. It was necessary, therefore, to establish a clear understanding with the A. W. S. in order to create an exchange of information and to avoid duplication of effort. It became apparent that it would be more profitable to leave such problems as the metallurgy of the welding processes, methods of testing the completed welds and organization of the procedure control, to the committees of the A. W. S.

Our efforts have been concentrated, therefore, on sponsoring the advancement of the theory of the electric arc, the design of the electric welding apparatus and the use of electric welding processes in the manufacture of electrical machinery.

The gathering of all available information on the progress of the art and the presentation of these facts through the medium of our annual report to the whole membership of the Institute is another important function of this committee.

As the activities of our committee have increased, it was felt at the beginning of the present fiscal year that the time had come to organize several subcommittees composed of physicists and engineers especially interested in one of the above specific problems. The committee as a whole has been concerned with the general survey of the advance in the progress of the art.

The present organization of subcommittees is as follows:

Research (Phenomenon of the Electric Arc) Dr. S. Dushman, Chairman, Dr. J. Slepian, Mr. H. M. Hobart, Mr. W. Spraragen, Mr. A. M. Candy.

Electric Welding Machinery (Designs of) Prof. F. Creedy, Chairman, Mr. J. C. Lincoln, Mr. A. M. Candy, Mr. A. Churchward, Mr. H. M. Hobart, Mr. K. L. Hansen.

Resistance Welding. The subcommittee on Resistance Welding has only been partly organized with Mr. E. Lunn and Mr. H. W. Tobey gathering preliminary information.

Papers

Through the efforts of the members of our committee, a symposium on welding was presented during the Winter Convention of the Institute. A paper by Dr. G. M. Shrum and Mr. H. G. Wiest, Jr. was presented by Dr. S. Dushman which related to the new experiments of the phenomenon of the electric arc.

Three papers were presented by Mr. J. H. Blankenbuehler, Mr. S. R. Bergman and Professor F. Creedy on the subject of the design of electric welding generators.

Two papers by Mr. M. Thomson and Mr. S. Martin, Jr. were on the subject of the resistance welding as applied in the manufacture of electrical apparatus.

Another paper on the design of the electric welding generator was published in the JOURNAL of the A. I. E. E. prior to the above Convention, by Mr. C. J. Holslag.

II. PROGRESS OF THE ART

General

The past year was characterized, first, by an outstanding improvement in the quality of the welds produced by various methods, secondly, by the refinement in the design of electric welding equipment, and thirdly, by the unprecedented expansion in the use of the resistance welding process.

The methods of testing and the procedure control attained such refinements that the quality of the welds produced on pressure vessels can be checked with accuracy.

The most outstanding accomplishment in the field of application of the electric arc in the past year, is the fabrication of 24 all-welded steam boilers by the Babcock & Wilcox Company for the United States Navy for installation on the new scout cruisers.

In the past, the arc welded oil stills for high pressure were manufactured successfully for a number of years by the A. O. Smith Corp., yet it is the first time that high-pressure steam boilers were fabricated by the electric arc and installed on the fighting ships.

Improvement in the Quality of Arc Welds

Arc welding was introduced into general use in this country during the World war. The first attempts to adopt the European method of welding with heavily fluxed electrodes, did not meet with general approval. Instead, the technique of welding with bare wire electrodes was developed to such an extent that practically all the arc welding in this country was done, until recently, by that method.

---

*COMMITTEE ON ELECTRIC WELDING:

P. P. Alexander, Chairman,
C. A. Adams,
A. M. Candy,
Alexander Churchward,
F. Creedy,
S. Dushman,
F. M. Farmer,
K. L. Hansen,
H. M. Hobart,
C. J. Holslag,
J. E. Kearns,
J. C. Lincoln,
Ernest Lunn,
B. T. Mottinger,
J. W. Owens,
J. Slepian,
William Spraragen,
H. W. Tobey.

Since the tensile strength of the welds produced with such electrodes is about the same as that made by the most expensive heavily fluxed electrodes of European make, for many applications the bare wire is entirely satisfactory. It should be noted, however, that both bare wire electrodes and heavily fluxed electrodes of European make produced welds lacking in ductility.

With the extension of the field of application of arc welding, it soon became apparent that for the use of arc welding on such structures as pressure vessels, electrodes of different types would be needed. Over ten years ago, work in this direction was started by the Electric Arc Cutting & Welding Co., Wilson Welder & Metals Co., and some other concerns and individual investigators, each of whom produced a new type of heavy or lightly covered electrode. These electrodes had certain advantages over the bare wire electrodes.

Decided advance in the improvement of the quality of the welds was made a few years ago by the General Electric Co. with the hydrogen gas shielding of the weld, by A. O. Smith Corp. with special wood pulp covered electrodes, and by several other individual investigators and concerns, each of whom developed in the last year or two, a very efficient type of fluxed electrode giving welds of high ductility, a quality which is absolutely essential for work on steam boilers and many other types of pressure vessels.

At the present time, several manufacturers of pressure vessels, in advertising their welds guarantee a ductility unheard of only a few years ago. The General Electric Co., A. O. Smith Corp., Blaw-Knox Co., Struthers-Wells Co., Kellog Company, Fusion Welding Corp., The Lincoln Electric Co., and Babcock & Wilcox Co. are probably only a part of the list of concerns now producing highly ductile welds. This advance in the quality of the produced welds opened new fields for arc welding, of which the steam boilers for the United States Navy is an outstanding example.

Resistance Welding

The welds produced by this process are of the highest quality with respect to strength, ductility and resistance to fatigue. The development, therefore, consisted mostly in the improvements in the design of the welding machines and application of such machines in new fields.

The most outstanding feature of the past year was the great development of welding pipes by the resistance process. Several machines up to 6,500 kva. each have been built for welding, by the flash welded process, longitudinal seams 40 ft. long. By the use of such machines, a weld 40 ft. long is produced simultaneously all along the seam and in less than one minute on pipe some 24 inches in diameter and of a plate up to ½ inch in thickness. Similar resistance welding machines of 1,200-kva. capacity weld circumferential seams of similar pipe. All the electrical parts for the above machines have been built by the Swift Electric Welder Company. A spot welder of 800 kva. with electrodes of 3½ inches in diameter, which probably is the largest machine ever built in this country, has been successfully built by the same Company for special heavy welding work.

Other concerns (amongst which the Thomson-Gibb Electric Welding Co. is the pioneer), developed the continuous method of seam welding. This last method had previously been used on a large scale for welding thin walled tubing. Within the last year, this method has been applied to the continuous seam welding of pipe of considerable diameter and wall thickness. At the present time, several manufacturing concerns are producing welded pipe up to 40 ft. long and it is expected that by butt welding two of such lengths in the factory, a pipe of 80 ft. long will be available for construction work.

This great development in the welding of industrial pipe by the resistance process was due to the decision of several large concerns to extend the pipe lines for transportation of natural gas and gasoline from the producing areas to the consuming districts over 1,000 miles away.

This development should be of especial interest to engineers since it indicates the possibility of transmission of power over longer distances by gas than have been accomplished by the electric current.

As was remarked by a well-known consulting engineer, the electrical engineer should rise to the occasion and surpass gas with respect to distance and amount of power transmitted. He has plenty of as yet undeveloped alternatives to the 60-cycle synchronous system as at present employed.

The resistance welding process is being further developed in the application to the automobile industry where it greatly outdistances all the other welding processes. Another important field of application of resistance welding is the manufacture of wire goods which comprises even such fields as the welding of wire netting for reinforced concrete. Machines making up to 24 welds simultaneously have been built and are in successful use. In the fabrication of electrical machinery, the resistance process has already been applied on a large scale to the manufacture of small transformer tanks. The application of this process has also extended to the fabrication of motor magnet frames.

Structural Steel Welding

In the field of structural steel, arc welding has already proved to be entirely satisfactory, and therefore, received further important applications. All arc welding of this type of construction is done with entire satisfaction with the bare wire electrodes.

Amongst the high buildings erected during the past year, (partly by welding and partly by riveting) are the buildings of the Southern California Edison Co., the Edison Electric & Illuminating Co. of Boston, and the DuPont Corporation at Wilmington, Delaware. The highest building entire'y welded was erected by the Dallas Power & Light Co. This building has 19 stories and measures 246 feet above the foundations. The Westinghouse company erected several industrial and office buildings, all entirely welded. The highest of these buildings measures 190 feet above the foundations. It should be noted that in the erection of the buildings, only very few welding machines are necessary. In the erection of the 19 story building at Dallas, only four arc welding machines were used.

Shipbuilding

In the shipbuilding field, arc welding is being extended rapidly and all our shipbuilding companies such as the Newport News Shipbuilding & Drydock Co., The Bethlehem Shipbuilding Co., and many others as well as the U. S. Navy Yards, are using arc welding quite extensively for fabricating various internal structures on ships. On smaller ships, the electric arc has been used successfully even in welding the hulls.

The Electric Boat Company, at Croton, launched during the past year, an all welded barge, 118 ft. long, of Ewertz patented design. The Federal Shipbuilding & Drydock Co., at Curney, N. J., welded a number of barges, and the Standard Steel Shipbuilding Corp., of Los Angeles, completed an all-welded 65-ft. yacht.

The application of arc welding in shipbuilding requires a careful study of the design of the welds and the details of the technique of welding. The long welded seams characteristic in this type of construction may be subject to high internal stresses and therefore should be produced by the best known methods and electrodes. The amount of welding per ton of steel in shipbuilding is very much greater than in the erection of buildings where only the short welds are necessary. It may be expected that in the construction of barges and small vessels for internal navigation, arc welding will soon outdistance riveting.

Automatic Machines, Alloy Electrodes and Special Arc Torches

The design of automatic arc welding machines advanced still further and several concerns are now manufacturing either full automatic or semi-automatic machines of a very efficient design for use with metallic electrodes. The Lincoln Company made further improvements in automatic carbon arc welding machines which produce welds of high ductility, and the General Electric Company applied the atomic hydrogen process to automatic welding as well as for hand welding.

The development of special alloy electrodes for hand welding as illustrated by the Stoody process, made considerable progress. The surfacing of various parts of machines subject to wear and abrasion with hard surfaces in certain cases can be successfully accomplished.

The development of special torches for use of indirect arc (similar to the flaming arc) extended the field of arc welding to the low-melting-point alloys. A special torch developed by Hansen and utilizing the d-c. arc can now be used for brazing, soldering, and welding low-melting-point extruded alloys. Another torch utilizing the a-c. arc has also been put on the market by the Warner Co., of Los Angeles. It can be used successfully on light work of brazing, soldering, and welding steel sheets of light gage.

Design of Electric Arc Welding Generators

The advances and refinements in the design of the electric welding generators have been carefully followed by the subcommittee on Electric Welding Machinery, which reports as follows:

An outstanding feature of the year's work in the development of direct-current arc welding generators, is the attention which has been devoted to their transient characteristics. It has been realized that the momentary shortening of the arc produces a large momentary transient current, which tends to cause explosions or "sputterings" detrimental to welding. Means have, therefore, been sought by several workers by which these momentary transient currents may be eliminated and papers on the subject have been presented by Blankenbuehler, Bergman, Holslag and Creedy.

The direct-current welding generators contain a main exciting coil either shunt, separately excited, or a combination of the two, and a demagnetizing series circuit whose function is to reduce the voltage with increasing current. One important type of transient is caused by the voltage induced in the main exciting circuit by transformer action from the series demagnetizing circuit and this type of transient may be eliminated by reducing this voltage to a small value. There is no need to eliminate this voltage altogether because it is only necessary to reduce it to such a degree that the solutions of the differential equations which determine the current approximate to the logarithmic instead of the oscillatory type. Blankenbuehler discussed a machine with separately exciting coil and reverse series winding only, and injects into the separately excited circuit a voltage proportional to the current flowing through the reverse series winding (the welding current) by means of a series transformer. This voltage is opposite in direction to that induced in the same coil by the reverse series winding so that the two tend to cancel.

The machine treated by Bergman has two distinct poles whose flux cuts the conductors between positive and negative brushes. One has constant flux and the other is shunt excited from a third brush intermediate between the main brushes, armature reaction being relied upon to reduce its voltage with increasing current. In this case a series transformer is used to inject into this shunt circuit a voltage proportional to, but opposite in direction to that due to induction from the armature.

In Creedy's machine in which the effect of shunt and separately excited windings is produced by a single coil, no transformer is employed but the same result is produced by reducing the reluctance of the main magnetic circuit so that the number of turns on the main exciting coil is very much reduced and consequently the e. m. f. induced in it by the series demagnetizing circuit becomes small. With this latter device a neutralizing winding becomes necessary to avoid sparking and excessive reactance of the armature winding.

Testing of Welds

Several non-destructive methods of testing of welds have been developed among which the X-ray method is already being applied as a regular procedure control on welds made on important structures. The magnetic and the stethoscope methods are also available. It should be noted also that a series of experiments has been conducted with the gamma rays produced by radium emanation for testing of welds on heavy plates and steel castings.

Further Research

Since the electric arc is the foundation on which the entire arc welding industry has been built, our subcommittee on Research recommends further study of this phenomenon. The outlined problems are as follows:

1. Probe measurements in arcs between iron electrodes, using a technique somewhat similar to that adopted by Nottingham in his investigations on the arc between copper electrodes in air.
2. Arc characteristics should be taken as a function of the pressure for different gases, such as carbon dioxide, air, and argon.
3. The question of the part played by fluxes, or additions of various "dopes" to the welding rod.
4. Determinations of the energy consumption at the electrodes, using a calorimetric method.
5. Accurate determination of cathode drop and its variations under varying conditions. This is an important factor in all theories of the electric arc and more accurate information on this point is certainly desirable.
6. Accurate determination of anode drop under varying conditions.
7. Study of small current arcs and particularly the glow to arc transition.
8. Mathematical study of some of the newer ideas on stability of discharges as developed by Barkhausen and others.
9. Cathode-ray study of stability of arcs such as used in electric welding. The spontaneous variations in current and voltage which are always taking place will probably be frequently beyond the capacity of the ordinary oscillograph. The influence of high frequency characteristics of the external circuit could be studied in this connection.
10. Stability of arc in magnetic field. Since arcs used in welding usually have quite strong magnetic fields, the influence of this factor in the stability of an arc is quite important.
11. Study of influence of nature of cathode surface on stability.
12. Study of influence of nature of anode surface on stability.
13. Study of passage of the deposited metal from the electrode to the work. Although a large part of the metal is deposited by liquid drops, it may be that a considerable portion passes in the form of vapor.
14. Study of the influence of superimposed alternating current of moderate and high frequency. The use of high frequency has been proposed for actual welding, but the influence upon the arc has not been studied in much detail.

It has also been suggested that the carbon welding arc be further studied, especially with respect to the blast of carbon vapor from the cathode spot.

University Activities

Through the initiative of the American Bureau of Welding, twelve engineering colleges and universities have become interested in various problems relating to welding. In addition to the research work conducted by professors, the students in several colleges write their theses on welding in preparation for the degree of B. S. or M. S.

It should be noted that welding, and especially electric welding, is receiving considerable attention in various universities abroad. Germany is probably leading in that respect because electric welding is considered to be of such importance that some colleges in that country confer the degree of Doctor of Engineering for any adequate research work on problems of welding.

In the Soviet Union, welding has received during the past year, an unprecedented expansion. To deal more adequately with the problem of a highly trained personnel, a special Welding Institute is being organized which will cost over $1,500,000, to train future welding engineers.

Electrical Machinery

ANNUAL REPORT OF COMMITTEE ON ELECTRICAL MACHINERY*

I. Organization and Activities

THE committee is organized with five permanent subcommittees, and its work has consisted of the review of papers, arrangement of programs for technical sessions, and the preparation of Standards and Test Codes.

Forty papers on electrical machinery were presented during the calendar year 1930. Others could have been made available if facilities for presentation and publication had permitted. The committee believes that the preparation of short and informal papers designed to bring out discussion at conventions should be encouraged, and that highly technical papers whose chief value is for reference should be presented before small groups in parallel sessions.

Standards

The Subcommittee on Transformers has been very active and during 1930 prepared "Recommendations for the Operation of Transformers" and brought to conclusion a revision of the A. I. E. E. Standards for Transformers.

The Subcommittee on Synchronous Machines, besides completing A. I. E. E. Standards for Capacitors, has initiated a number of revisions for the A. I. E. E. Standards for Synchronous Machines.

The Subcommittee on Mercury-Arc Rectifiers is working in close cooperation with the Sectional Committee on Rectifiers, which has under preparation Standards for Mercury-Arc Rectifiers.

Test Codes

Preliminary drafts of test codes for transformers, induction motors, direct-current machines and synchronous machines have been prepared. These codes are intended to provide definite instructions for the more generally applicable field and factory methods of conducting and reporting acceptance and other tests of general commercial value.

II. Resumé of Progress of the Art

SYNCHRONOUS MACHINES

Steam-Turbine Driven Alternators

The size of the single-shaft units has again been increased, two 200,000-kva., 0.8 power-factor, 1,800-r. p. m., single-shaft, tandem-compound, turbine-generator units (GE)† now being built for the Hudson Avenue Station of the Brooklyn Edison Company. They have double windings rated at 16.5 kv., and double-winding auto-transformers will step up the voltage to 27.6 kv.

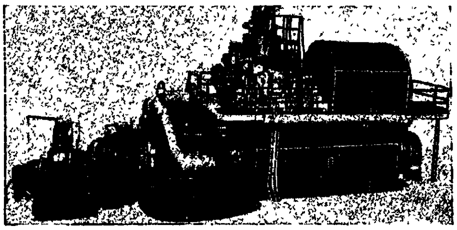

FIG. 1—50,000-KW., 3,600/1,800-REV. PER MIN., VERTICAL-COMPOUND, TURBINE-GENERATOR UNIT (GE)—PACIFIC GAS & ELECTRIC CO.

A 110,000-kw., 1,200-lb., vertical-compound, double-winding turbine-generator unit (GE), with duplicate generators on the high- and low-pressure turbines, has been constructed for the Ford Motor Company.

A 50,000-kw., 3,600/1,800-r. p. m., 1,200-lb. unit, in which the high- and low-pressure elements were combined to form a vertical-compound turbine-generator set (GE) was constructed for the Pacific Gas & Electric Company and a duplicate unit is nearing completion. (Fig. 1.)

Three 18,750 kva., 3,600-r. p. m., turbine-generator units (W), the largest machines of this speed yet manufactured in this country, were put in operation at Baton Rouge by the Louisiana Steam Products Company. An outstanding feature of these machines is the internal propeller fan used, the success of which has created a new interest in internal fans for large machines.

High-voltage turbine generators rated 121,000 kva., 18 kv.; 147,000 kva., 22 kv.; and 94,000 kva., 22 kv. are now in the first stages of construction (AC).

The satisfactory completion of tests on a 9,375 kva.

---

†Legend for Manufacturer Designation:

In order to conserve space and avoid numerous repetitions of the names of manufacturers, the following designation has been used throughout the report:

AC—Allis-Chalmers Manufacturing Co.
BB—American Brown Boveri Co.
CGE—Canadian General Electric Company
CW—Canadian Westinghouse Co., Ltd.
EM—Electric Machinery Mfg. Co.
GE—General Electric Co.
W—Westinghouse Electric & Mfg. Co.

hydrogen cooled, turbine generator (W) (Fig. 2) have encouraged the serious consideration of hydrogen cooled turbine generators for ratings above 30,000 kva.

Waterwheel-Driven Alternators

The year 1930 has been notable for the number of large hydro-electric developments which have either been contemplated or put into operation. Table I is a list of some of the more interesting hydraulic-driven generators installed or under construction during the past year.

The 77,500-kva. generators (GE) for the Dnieper River Development in Russia, operating under a hydraulic head of 123 feet are the largest waterwheel generators yet constructed. (Fig. 5.) The total weight of each generator will be approximately 880 tons, the weight of the rotor and shaft will approach 445 tons, and the shaft itself, which is 36 ft. long and 40 in. in diameter, with a 70-in. flange on each end, will weigh about 68 tons. The stator is fabricated in six sections with punchings and windings assembled in each section before shipment.

*Included in report of last year.

The 31,111-kva., 109-r. p. m., umbrella-type generators (GE and W) for the Safe Harbor Development of the Pennsylvania Water & Power Company are to be driven by Kaplan-type turbines, and will operate as motors in a reversed direction to pump water back into the fore-bay for use during the peak-load periods.

High Frequency Generator

A 500-kva., 960-cycle generator (W) built for the American Brass Company will supply power for an electric furnace. The rotor required special construction to retain the field coils in place at the high peripheral speed of 20,000 ft. per minute.

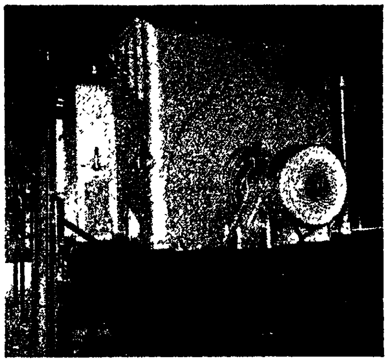

Fig. 2—9,375 Kva., Hydrogen-Cooled, Turbine-Generator (W)

A 666-kva., 960-cycle single-phase generator (GE) was placed in operation at Watertown (Mass.) Arsenal in November, 1930, and a 750-kva., 960-cycle, three-phase generator (GE) is being built for the American Brass Company.

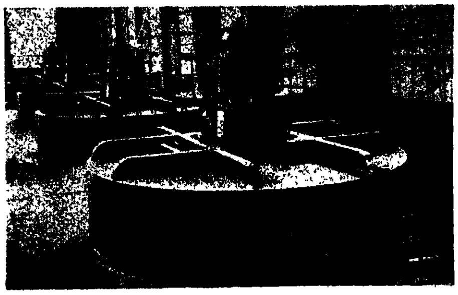

Fig. 3—Four 40,625-Kva., 138.5-Rev. per Min., Umbrella-Type, Waterwheel-Generator Units (W)—Saluda Development, Lexington Water Power Co.

Synchronous Condensers

A 50,000-kva., 13.2-kv., 600-r. p. m., 50-cycle hydrogen-cooled condenser (GE), equal in capacity to the largest air-cooled machines, has been constructed for the Southern California Edison Company. (Fig. 6.) The total capacity of hydrogen-cooled condensers now in service is 137,500 kva. with 70,000 kva. additional on order.

Two 15,000-kva., outdoor hydrogen-cooled condensers (W) have been constructed; one rated at 50 cycles, 750 r. p. m. for the Southern California Edison Company, and the other rated at 60 cycles, 720 r. p. m. for the Indiana & Michigan Electric Company.

A 7,500-kva., 6.6-kv., 900-r. p. m., 60-cycle air-cooled, outdoor condenser (AC) has been constructed for the Central Illinois Public Service Company. (Fig. 7.)

Industrial Synchronous Motors

The application of synchronous motors to industrial purposes is being extended as the knowledge of the starting, acceleration, and pull-in requirements is increased and as the prediction of these characteristics becomes more exact. A number of unique designs has been developed during the year.

A 500-hp., 72-r. p. m., vertical-shaft motor (GE) has been applied to a Fuller Lehigh coal pulverizer, in which the motor frame forms the base on which the pulverizer is built. The motor develops considerably more than normal torque from start to pull-in in order to obtain successful starting with a choked mill. Overvoltage for starting is supplied by a step-up autotransformer.

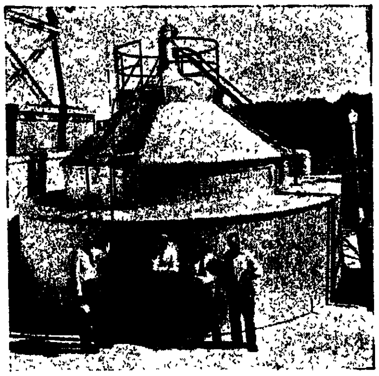

Fig. 4—4,000-Kva., 128-Rev. per Min., Vertical-Type, Outdoor, Waterwheel Generator (W)—Merced Falls, San Joaquin Light & Power Co.

A 700/350-hp., 2.3-kv., 277/138-r. p. m., three-phase, 60-cycle, two-speed synchronous motor (W) has been applied to a vertical centrifugal pump for the Ford Motor Company.

A new method for securing reduced starting kva. has been introduced, which utilizes the inherent reactance of the motor itself, a 3,000-hp. (GE), five 3,500-hp. (EM) and several smaller motors having been built. The stator is wound with two or more parallel circuits so arranged within the core as to obtain increased reactance when only one of the circuits is energized. The starting characteristics obtained are somewhat similar to those secured by using external reactors in series with the lines.

A 600-hp., 440-volt, 300-r. p. m., three-phase, 60-cycle, synchronous motor (EM) was applied for the first time for continuous reversing duty on a copper rolling mill, synchronous motors having been generally considered unsuitable for constant reversing duty on account of their inferior starting characteristics. The operating requirement that the mill be reversed from full speed forward to full speed reverse in five seconds necessitated special design of the stator and rotor to dissipate heating, which was accomplished by the use of ventilating spacers in the armature core and field poles and by special cage end-ring construction. (Fig. 8.) Three parallel circuits were used in the stator, which were switched successively both for forward and reverse acceleration in order to reduce the increment starting kva. demand.

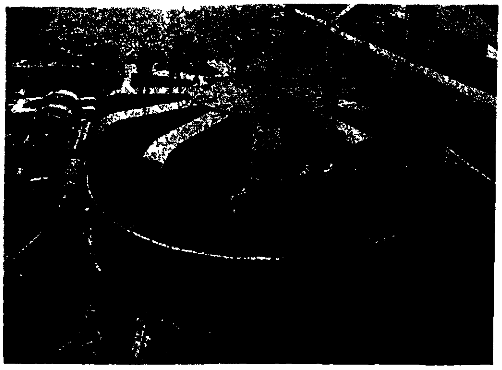

FIG. 5—77,500-KVA., 88.25-REV. PER MIN.. VERTICAL-TYPE, WATERWHEEL GENERATOR (GE)—DNIEPER RIVER DEVELOPMENT (RUSSIA) AMTORG TRADING COMPANY

A slow-speed, vertical-shaft motor (EM) has been incorporated in a pulp hydrator base. The motor was provided with a thrust bearing which carries the weight of the rotor and hydrator rotating member. To permit adjustment of the clearance between the rotating and stationary members of the hydrator, the motor was provided with a micrometer raising and lowering device, the field poles being slightly longer than normal to permit a moderate movement of the rotor axially with respect to the stator.

FIG. 6—50,000-KVA., 13.2-KV., 600-REV. PER MIN. 50-CYCLE, HYDROGEN-COOLED SYNCHRONOUS CONDENSER (GE)—SOUTHERN CALIFORNIA EDISON CO.

Marine Synchronous Motors

Several electric-propelled vessels of interesting design were placed in service or are under consideration.

TABLE II—MARINE SYNCHRONOUS MOTORS

†Included in report of last year.
‡Under construction.

The 13,250-hp., 133-r. p. m. ship-propulsion motors (GE, W) are the largest marine synchronous motors yet built. These motors are completely fabricated.

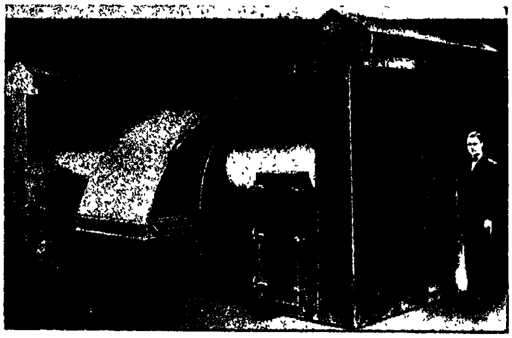

FIG. 7—7,500-KVA., 6.6-KV., 900-REV. PER MIN. 60-CYCLE, AIR-COOLED, OUTDOOR, SYNCHRONOUS CONDENSER (AC)—CENTRAL ILLINOIS LIGHT CO.

Frequency Converters

There is a growing tendency to install large machines outdoors in order to reduce building costs. The first frequency-converter units to be so installed have been built during 1930 and will be placed in operation during 1931.

Two such units, the generators being rated at 21,000 kva., 0.7 power factor, 300 r. p. m., 25 cycle, one-phase, and the motors at 18,000 kva., 0.9 power factor, 300 r. p. m., 60 cycle, three-phase (W) will be installed at the Wayne Junction Substation of the Philadelphia Electric Company to supply power for the new Reading Railroad Electrification (Fig. 9). Conventional indoor design was followed, with spring mountings to absorb the single-phase torque pulsations, the machine being adapted for outdoor service by enclosing in a sectionalized sheet steel housing approximately 64 ft. long by 25 ft. wide.

INDUCTION MACHINES

A major activity of the manufacturers during the year has been the development of new lines of induction motors to conform with the frame sizes and mounting dimensions standardized by the National Electrical Manufacturers Association as announced in last year's report. In many cases this program has included a change in electrical design to improve the noise and torque characteristics. Much attention has also been given to the appearance in order to meet the ever more exacting aesthetic tastes of the public.

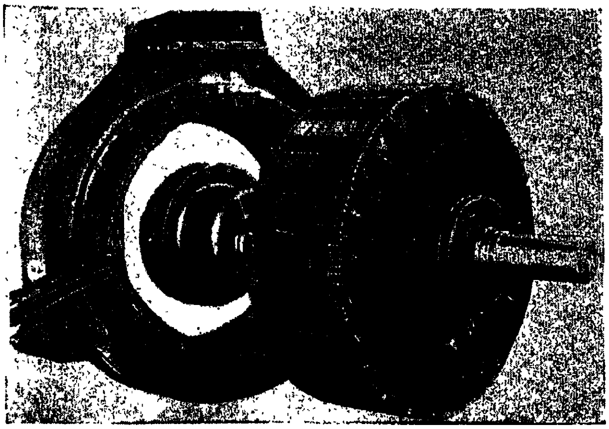

FIG. 8—600-HP., 440-VOLT, 300-REV. PER MIN. 60-CYCLE, CONTINUOUS-REVERSING-DUTY, SYNCHRONOUS MOTOR (EM)—COPPER ROLLING MILL

Several manufacturers now furnish lines of motors in integral up to 100 hp. as well as fractional horsepower sizes for class I and class II hazardous locations (inflammable gases and combustible dust) as defined in the National Electrical Code.

Complete lines of totally-enclosed, fan-cooled continuous duty 55-deg. cent. motors as large as 250 hp., particularly suited for use in harmful dust conditions, have now been developed by many manufacturers and the use of this type is steadily growing.

An extensive application of a novel induction motor (GE) has been made to conveyor tables in steel mills. (Fig. 10.) The conveyor roller is a hollow cylinder mounted on ball or roller bearings rotating around a stationary supporting shaft on which the stator is mounted. The cylindrical convey roll, which surrounds the stator, serves as a secondary, the induced currents flowing in the solid steel inner surface of the roll.

D-C. MACHINES

Motors and Generators

An 8,000-hp., 800-volt, 40- to 100-r. p. m., motor, having a peak capacity of 22,000-hp., 2,900,000-lb. ft. torque, has been built (GE) for a blooming mill of the Illinois Steel Company. This is the largest single-armature motor employing fabricated construction for the major parts.

Two 5,000-hp., 40-r. p. m., double-armature motors were built (W) for operating the main rolls of the new 10,000-hp. blooming mills at the South Chicago Plant of the U. S. Steel Corporation, which is the most powerful mill yet built. Each of the two main rolls is driven by one of the motors, the two being kept at the same speed by electrical control instead of being geared together as in former installations. Each double motor has a peak-torque capacity of two million lb. ft. Power is supplied from three 3,000-kw. induction motor-generator sets. The series fields of the three generators are interconnected in such a way that parallel operation is secured with satisfactory division of load.

Planer motors up to 75 hp. rating with speed ranges by field control of 6 to 1 have been developed (GE and W), and further increases in size of this class of motor are under consideration.

A 50-hp., 1,600-r. p. m., 75-deg. cent. one-hour motor has been developed (W) for application on a coal cutter to meet a limiting over-all height of 12 in.

Six 3,500-hp., 330-r. p. m,, motors have been constructed (AC) for a 96-in. plate mill of the Illinois Steel Company. Power is supplied by two 6,000-kw. synchronous motor-generator sets.

Two motor-generator sets, consisting of two 3,000-kw., 600-volt, compensated generators driven by one 6,500-kva. synchronous motor, have been constructed (GE). These sets will deliver 6,000 kw. continuously with 9,000 kw. for two hours or 7,500 kw. continuously without overload.

Exciters

Further developments in "rapid response" exciters have occurred during the year, with the objects of securing higher efficiency and improved control. Th use of a special Wheatstone Bridge type of rheostat (GE) enables the exciter to operate down to zero or even reversed voltage.

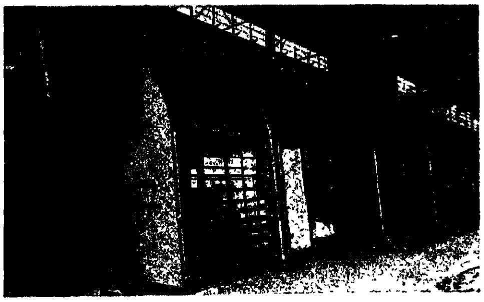

FIG. 9—21,000/(18,000)-KVA., 300-REV. PER MIN.. 25-(60)-CYCLE, ONE (THREE) PHASE, FREQUENCY-CONVERTER OUTDOOR HOUSING (W)—WAYNE JUNCTION SUBSTATION, PHILADELPHIA ELECTRIC CO.

A 90-kw., 3,600-r. p. m., direct-connected, turbine-generator exciter has been developed (W) which is one of the largest exciters ever built for this speed. (Fig. 11.)

Synchronous Converters

Four 5,440-kw., 167-r. p. m., 16,000-ampere, 25-cycle, synchronous converters were constructed (2 GE and 2 W) for a chemical plant in the Niagara Falls District. The converters are enclosed in volute housings, and the outgoing air is discharged outside the building. Direct-current voltage adjustment is obtained by means of tap-changing equipment on the supply transformers. A novel feature of construction used on two of these machines (GE) is a "tandem" commutator, which consists of two sets of shorter copper segments, together with insulation and clamping rings, mounted on a common support so arranged that air can pass between the adjacent ends of the two commutators where their segments are connected together. This construction (Fig. 12) results in lower temperature rise and smaller expansion strains and, consequently, a smoother running surface than is usually obtained with an equivalent single-unit commutator.

TRANSFORMERS

Power Transformers

Extensive theoretical and experimental study of transient voltage phenomena was continued during the year, and the development of means for protection against lightning surges advanced rapidly. One indication of the progress made during the year is given by the successful outcome of full voltage flashover tests on a large transformer.

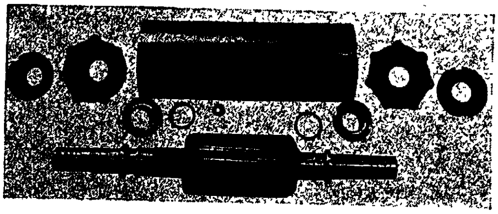

FIG. 10—40-LB.-FT., 250-VOLT, 125-REV. PER MIN., 25-CYCLE, CONVEYOR-ROLLER INDUCTION MOTOR (GE)

A 13,000-kva., 230-kv., wye-grounded, non-resonating transformer built for commercial use (GE) was subjected to a series of artificial lightning voltage tests. The transformer was connected to a lightning generator by a short transmission line insulated with fourteen 10-in. units, spaced 5¾ in. in suspension, which is used quite generally for 230-kv. service. The insulator strings were repeatedly flashed over without apparent damage to the transformer. The line insulation was then increased until the transformer bushings were flashed over. The transformer was subjected to repeated waves both above and below the bushing flash-over voltage, after which it withstood all A. I. E. E. standard tests.

A study of transient voltage phenomena within auto-transformer windings resulted in the development of the non-resonating auto-transformer (GE), of which several have now been built for 230-kv. service.

Through the development of the grounding neutral impedor (GE), the use of the non-resonating transformer was extended to include banks with neutrals isolated or grounded through resistance or reactance.

Investigation (W) has shown that a comparatively high resistance can be used in the neutral of a bank of power transformers and the bank will perform practically the same as though it were solidly grounded. The same result can be obtained with reactance in the neutral paralleled by a protective device, such as a lightning arrester. The internal voltages at points within the winding have been found to be practically identical for a bank with a solidly grounded neutral and for one with a reactance paralleled by a lightning arrester.

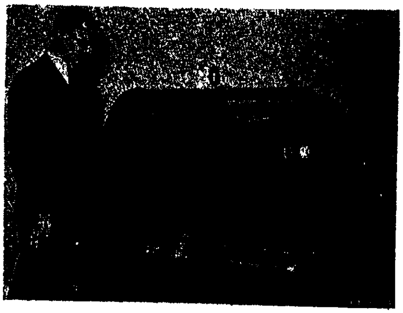

FIG. 11—90-KW., 3,600 REV. PER MIN., DIRECT-CONNECTED, TURBINE-GENERATOR EXCITER (W)

In order to extend the benefits of load-ratio control to small transformers, a lighter type of equipment has been developed for 15-kv. service (GE). This consists of a multi-point switch which permits the load current to leave each tap point over two paths; *i. e.*, over two switch arms which connect to the bridging reactor. A typical application of this equipment is represented by a 3,333-kva., 69.7/115 Y-13.8-kv., one-phase transformer, in which thirteen operating positions are provided by the installation of the control device in the low-voltage winding. In this type of construction all moving parts, that is, the ratio adjuster and two contactors, are mounted outside the main transformer tank.

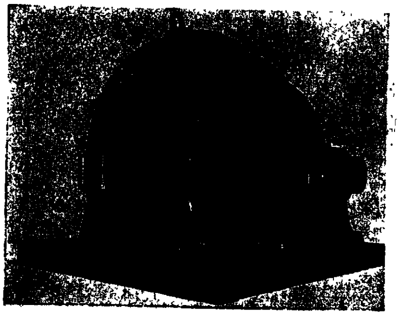

FIG. 12—5,440-KW., 340/270-VOLT, 16,000-AMPERE, 25-CYCLE, SHUNT-WOUND, SYNCHRONOUS CONVERTER WITH TANDEM COMMUTATOR AND BRUSHES (GE)

Several 5,000-kva., 13.2-kv., three-phase, furnace transformers, with a new type of tap-changing equipment, have been built (W) for the Ford Motor Company. These transformers deliver a normal low-voltage current of 12,800 amperes at 225 volts, with a maximum current of 19,200 amperes at 150 volts. A special motor-operated tap changer provides six different delta low voltages and a change from delta to star on the high-voltage winding gives six additional delta low voltages. Two individual tap changers are operated by one motor and all the voltages and connections are obtained by the operation of a single control switch at the switchboard.

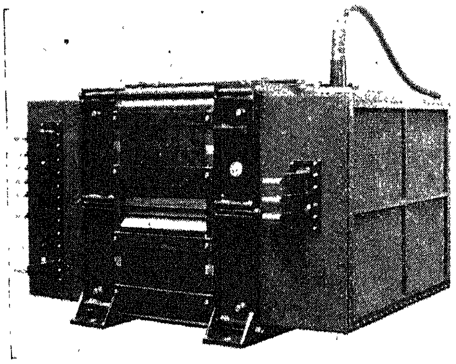

Fig. 13—4,200 Kva., 11,000,-915-46 Volts, 25-Cycle, Air-Blast, Locomotive Transformer (GE) (W)—Pennsylvania R. R.

A 4,200-kva., 11,000-915-46-volt, air-blast transformer of special construction was built (coordinated design of GE and W) for installation in a locomotive where space is at a premium. (Fig. 13.) It was, accordingly, designed for minimum dimensions and weights, the floor space occupied being 6 ft. 8 in. by 7 ft. 3 in. and the total weight being approximately 26,000 lb. A 2,800-kva. transformer of the same type has also been developed. These transformers are suction air-cooled and of exceptional mechanical strength, being braced and insulated for the severe operating conditions incident to locomotive service.

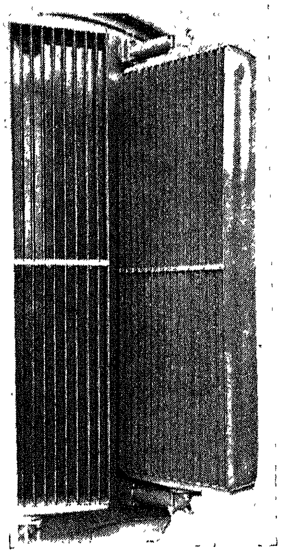

Fig. 14—Outside-Edge-Welded Transformer Radiator (W)

Power-Transformer Auxiliaries

While the method of cooling transformers by means of "banked" radiators was not used to any great extent following its development several years ago, it was extensively applied during the past year. About 200,000 kva. in transformers of this construction are in service and more than 600,000 kva. are now under construction (GE).

A new type of transformer radiator has been developed to replace the tubular type on all Westinghouse large self-cooled power transformers. (Fig. 14.) All of its joints are formed with edge welds on the outside of the radiator, and there are no crevices or flat surfaces where water can accumulate. The open construction facilitates cleaning and painting.

A 20,000-kva., 66-22-kv., load-ratio-control transformer, equipped with unusual pothead disconnecting switches has been built (W) for the State Line Generating Company. These high-voltage switches disconnect the transformer from the line and connect test bushings to the 66-kv. cable lines, which can then be tested with 330 kv., direct current. The pothead equipment also included oil reservoirs used to maintain pressure on the oil-filled cables to which the transformer is connected.

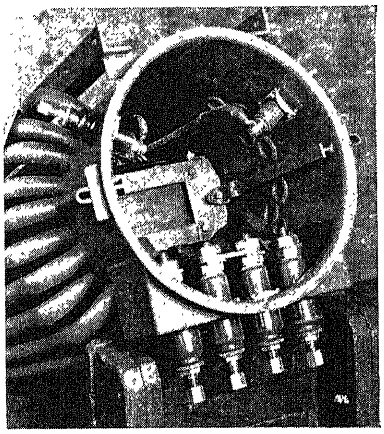

Fig. 15—100-Kva., 2,080-115/230-Volt, 60-Cycle, Distribution Transformer Equipped with Detachable Bushing (AC)—Commonwealth Edison Co.

A new no-load ratio adjuster has been developed (BB) which is operated through the side of the tank wall instead of the cover, making it more convenient to operate and permitting the tap position to be safely checked without deenergizing the transformer. A novel form of connection is used between the internal and external parts which permits engagement or disconnection of the two parts, when the transformer core is tanked or untanked, without the necessity of crawling inside to remove pins, bolts, etc.

Distribution Transformers

A new single-bushing, single-phase transformer has been designed (GE) for 110-kv. rural service. It is arranged for connection from line to neutral on a 110-

kv. circuit, which is insulated for 132-kv. service. In order to secure a low over-all height, the interior was so constructed as to give the equivalent of an inverted winding. The bushing was then connected to the bottom of the coil stack, thereby effecting a low height in spite of the large size of the bushing and the amount of insulation required for operation on a 132-kv. insulated line.

A detachable bushing has been developed (AC) for distribution transformers, particularly for installation where lightning conditions are abnormally severe, which can be replaced without removing the case from the pole. (Fig. 15.)

Rectifiers

The installation of rectifiers has continued to increase at a rapid rate, particularly when measured in terms of the aggregate kw. capacity.

	No.	Kw.
Put into operation during 1930	33	75,225
Put into operation during 1929	30	48,125
Increase	10%	58%
Put into operation during 1930	33	75,225
Being erected during 1930	26*	71,400*
On order at end of 1930	29	79,275
Total for 1930	88*	225,900*
In service at end of 1929	90	102,309
Grand total	178*	328,209*

*In addition one spare 500-kw. rectifier tank (without transformer) was supplied.

The mercury-arc rectifiers put into operation and being erected during 1930 and on order at the end of the year are shown in Table III.

The placing in operation of fourteen units with an aggregate rating of 40,000 kw. of 3,000-volt rectifiers

TABLE III—MERCURY-ARC RECTIFIER UNITS PUT INTO OPERATION DURING 1930 OR ON ORDER DECEMBER 31, 1930

Purchaser	No. of sets	D-c. volts	Kw. per set	Total kw.	Control	Service	Put in service	Manufacturer

*In addition one spare 500-kw. rectifier tank (without transformer) was supplied.

on the Delaware, Lackawanna & Western Railroad Electrification (Fig. 16) was the outstanding event of this year. This is the first installation of 3,000-volt rectifiers in the United States and the first use anywhere of so great a capacity of such units. It is also the first instance of a major railroad electrification relying entirely on rectifiers for the supply of power. These rectifiers are equipped with excited grids and with automatic compounding.

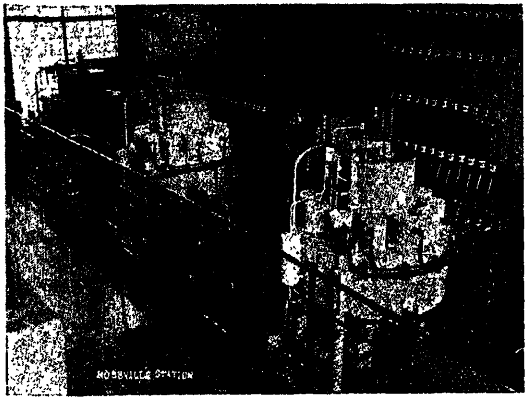

FIG. 16—3,000-KW., 3,000-VOLT, MERCURY-ARC RECTIFIERS (GE)—ROSEVILLE SUBSTATION, DELAWARE, LACKAWANNA & WESTERN R. R. ELECTRIFICATION

Another outstanding feature is the very large number of units ranging in voltage from 550 to 650 volts with a current rating in excess of 3,000 amperes, notable among which are 23 sets (GE) with an aggregate capacity of 69,000 kw. on order by the New York Board of Transportation. (The first seven units of this order were reported last year under the heading "City Subways of New York.")

Five units (BB), having a normal rating of 4,650 amperes at 650 volts, with overload ratings up to 15,000 amperes for twenty seconds, are being erected for the Long Island Railroad (Fig. 17). These rectifiers have eighteen anodes and normally operate from a 25-cycle source of supply but are arranged for immediate throw-over to a 60-cycle source of supply in the event of failure. The transformers are also suitable for operation at either 11 or 33 kv.

A 2,200-kw., high-voltage electric furnace set is also being erected (BB). The d-c. voltage may be varied from 3,500 to 9,600 volts by means of load-ratio control on the rectifier transformer. This is the highest voltage for commercial rectifiers which has been reported in this country. Smaller units of higher voltage have, however, been used for large radio broadcasting stations in Europe.

Electrochemistry and Electrometallurgy

ANNUAL REPORT OF COMMITTEE ON ELECTROCHEMISTRY AND ELECTROMETALLURGY*

THIS report covers the period 1929 and 1930, inasmuch as no report was made in 1929.

It is believed worthwhile to indicate the magnitude of the electrochemical and electrometallurgical industries in terms of installed capacity and yearly power consumption. The figures for the United States are as follows:

Approximate installed operating capacity, kw	7,000,000
Approximate percentage of National total generating capacity	18
Approximate annual power consumption, kw-years	4,900,000
Approximate percentage of total	36
Number of workers	1,000,000
Value of product	$12,000,000,000

Quantities and percentages such as these would seem to warrant the liveliest interest on the part of men having electrical engineering training, particularly the younger men who find themselves faced with limited opportunities for advancement in those more standardized fields of the electrical art involving the design and manufacture of apparatus for the production and distribution of electrical energy. The development of new materials or processes based upon the utilization of this power is a field requiring talent of high order and one which it seems should be very attractive to men of electrical training who can and will superpose on an electrical background a knowledge of the fundamentals of physical chemistry.

Below is given a list of the more important industries whose basic processes are dependent upon the utilization of electricity for other than mechanical purposes:

Production of Metals by Wet Electrolysis. Copper, Nickel, Sodium, Zinc.

Production of Metals from Fused Electrolytes. Aluminum, Barium, Beryllium, Calcium, Magnesium.

Non-Metallic Electrolytic Products. Caustic, Chlorine, Hydrogen, Oxygen.

Electrothermic Products. Abrasives, Carbides, Carbon, Ferro-Alloys, Graphite, Refractories.

Miscellaneous. Cleaning and Surface Treatment of Metals, Dry Cells, Electric Steel Melting, Electrolytic Synthesis Organic Compounds, Electroplating, Electrostatic Precipitation, Inductive Melting and Heating, Nitrogen Fixation, Pasteurization and Sterilization, Secondary Batteries, Water Purification, Welding.

When the process problems of these industries are analyzed it will be found that they should be attacked by men who have been trained to deal with intangibles, and that most of the phenomena may be resolved into elements among which an electrical engineer who has been soundly trained in the basic science of his art should feel at home. Pursuit of these problems will probably lead him far from consideration of the newest thing in circle diagrams or the latest refinement in slot design but he will have broader scope for his imagination and the mental technique bred by electrical training.

The foregoing comments have been made because there are many who feel that the electrical industry is more in need of increased outlet for power than of further small gains in the efficiency of electrical apparatus *per se,* and that the great body of expectant young electrical engineers must look for adequate opportunities for advancement more to the fields of utilization and electrical processes than to the conventional ones of apparatus and generation.

Below is given an outline of the more important developments in electrochemical and electrometallurgical art that have become known during the past two years.

Copper

Although copper refining is probably the largest of the electrochemical industries in point of tonnage, no important modifications of electrochemical process have been reported although operating economies have been improved by advances in mechanical equipment and materials handling facilities.

Sodium

Metallic sodium is now being produced on such a large scale and so cheaply by electrolytic methods that it is the cheapest pure metal in terms of cost per unit volume. Its electrical conductivity is high enough so that its cost on a conductivity basis is lower than that of any other metal. These facts have led to a proposal that electrical conductors be formed of metallic sodium enclosed in a thin-walled tube of some non-magnetic alloy steel.

Metallic sodium is finding increasing application in connection with certain synthetic organic reactions whose nature is not disclosed and certain electrochemical interests are said to be preparing to manufacture sodium on an unprecedented scale.

J. L. Woodbridge,
C. D. Woodward.

Zinc

The success of electrolytic zinc refining plants was noted in the 1928 report of this committee. This development has since been subject to severe competition because of improvements in thermochemical methods. Electrothermal methods have also received the attention of investigators and it is probable that another year will see marked changes in zinc technology due directly to the application of electricity in one way or another.

Aluminum

The Hoopes process of producing very pure aluminum has become of increasing commercial importance, particularly for containers for various articles in the drug and pharmaceutical field. Although the electrical conductivity is appreciably higher than that of ordinary commercial aluminum it has not been commercially applied as electrical conductor material. Accurate alloy investigations have been made possible by this very pure material and the knowledge thus gained has assisted materially in the development of the strong aluminum alloys.

The usual Hall process rarely produces aluminum purer than 99.7 per cent, while the Hoopes process is regularly producing metal better than 99.98 per cent pure and some metal has been produced by this process having a purity of 99.99 per cent. The process is carried out in a three-layer cell, wherein the metal to be purified exists as a molten anode alloy and rests on the bottom of the cell. The electrolyte consists of a mixture of cryolite, aluminum fluoride and barium fluoride. The purified aluminum is electrolytically deposited in a layer of pure molten aluminum floating on top of the electrolyte. Graphite electrodes are employed to lead the current out of the aluminum layer. The cell operates at a voltage varying from 5 to 7 volts and normally a current of 20,000 amperes is employed.

By anodic treatment in wet electrolytic cells aluminum may be given a tough, adherent and corrosion resistant surface of oxide which serves as a base for color and which is also finding use for protection of aluminum alloy aircraft structure from severe corrosion attack such as that of salt spray and sea-water. This development is still going forward rapidly and is expected to become of much greater importance in aluminum technology.

Electro-plating with aluminum on copper and other base metals has been accomplished by the use of a fused electrolyte of low melting point comprising the chlorides of aluminum and sodium. Tough, adherent, and non-porous deposits of pure aluminum are produced and many commercial uses will no doubt be found as the technique is improved.

Barium

Barium is one of the alkaline-earth elements and is characterized by great reactivity and interesting thermionic properties. It is produced by the electrolysis of fused barium salts and has been receiving considerable attention because certain of its alloys have useful thermionic properties. It has found commercial application in a nickel-base alloy for spark plug electrodes and has been of interest as an essential constituent of alloys intended for use as cathodes in thermionic devices. Such barium alloys are, in general, electric furnace products.

Beryllium

During the past few years the metal beryllium has received a great deal of attention, which has been primarily due to the results of systematic research both in this country and abroad. Beryllium may be produced by an electrolytic process which consists of the electrolysis of mixed beryllium oxyfluoride and barium fluoride. The only commercial ore of beryllium is a silicate of beryllium and aluminum. The beryllium oxide content of available ores lies between 6 and 12 per cent. The production of beryllium has been carried out both in this country and abroad.

The future of beryllium does not appear to lie in its use as a basic material, but rather as a minor constituent in more or less complex alloys.

About the only use thus far developed for the pure metal is as windows in X-ray tubes, inasmuch as beryllium is extremely transparent to X-rays. Experimental use in pistons and piston rings has been reported. Continued research will doubtlessly develop new uses for this interesting metal, inasmuch as it possesses a combination of high elastic modulus, low expansivity and lightness which is very attractive to many who are interested in mechanical developments. Its electrical resistivity is approximately 6.7 microhms per cu. cm. at room temperature.

Magnesium

This metal is produced by the electrolysis of molten magnesium chloride and more recently by means of processes in which magnesium oxide is dissolved in a bath of fused fluorides and decomposed by electrolysis to give the metal. The production of magnesium in the United States has increased from approximately 50,000 lb. in 1921 to more than 1,000,000 lb. in 1930. During 1930 magnesium forgings have appeared on the American market and with continued research it is expected that increased quantities of strong magnesium alloys in the form of castings and forgings will be rather extensively employed particularly in aircraft. With improved production technique purer metal is being produced and the susceptibility to corrosion lessened in consequence.

The outstanding difficulty in the way of increasing the use of magnesium has been the development of suitable alloys and fabricating processes and great strides are being made in this direction.

Electrotechnology of Gases

The treatment of gaseous mixtures by electrical discharges in order to effect chemical reactions that would not ordinarily occur has received a great deal of attention. The work of Fischer and Peters in Germany is particularly interesting in that they find it possible to produce acetylene from methane with an energy consumption that compares favorably with that required by the conventional calcium carbide process. The cracking of heavy hydrocarbon vapors by corona discharge also shows some possibilities. A great deal of research is going on in connection with the chlorination of hydrocarbons such as methane, pentane, etc., and this promises a considerable expansion in the use of chlorine, which is an electrolytic product. Research investigations of the chemical effects of bombardment by high-speed electrons should also be mentioned.

Abrasives—Carborundum

Tungsten carbide cutting tools have found increasing application and this has necessitated the development of improved abrasive wheels for shaping them. As a consequence special grades of carborundum are being made, apparently of unusual purity, from which grinding wheels specially adapted to the shaping of carbide tools are made. Carborundum base resistors for high temperature electric heating furnaces have been considerably improved, and several manufacturers have designed about this type of resistor commercial furnaces for operating temperatures between 1,000 deg. and 1,400 deg. cent.

Aluminum silicate refractories of very high melting point are being fused in electric furnaces and cast into blocks and shapes for various purposes, particularly for parts for glass-melting furnaces. The melting and casting of such highly refractory substances is a new and interesting departure in industrial ceramic technology.

Cleaning of Metals

A wet electrolytic process for the removal of scale from metals which is said to be competitive with pickling and free from many of its objections has been put on a commercial basis. Hydrogen embrittlement is prevented by the automatic deposition of a thin film of lead on any area of clean metal as soon as it is exposed by scale removal. This lead film may be allowed to remain as a protection against corrosion or removed by anodic oxidation by reversal of the electrolyzing current.

Electrochemical Standards

The interest in our electrochemical standards for the international ampere and the international volt has been continued and during the coming summer cooperative measurements on these standards will be carried out at the Physikalisch-Technische Reichsanstalt. For this purpose Dr. G. W. Vinal, Chief, Section of Electrochemistry, U. S. Bureau of Standards and a member of this Committee is being sent to Germany. He will also make measurements at the Laboratoire Central d'Electricite in Paris, and the National Physical Laboratory in England.

Primary and Secondary Batteries

During the past year the American standard for dry cells has been revised and a new standard approved by the American Standards Association. This standard has been published by the Association and also by the Bureau of Standards as Circular No. 390. The technical requirements of the Government specifications are identical with those of the American standard, but the Government specification is being revised to accord with the form prescribed by the Federal Specifications Board for all Government specifications.

The Federal specifications for automotive storage batteries have been approved and published during the year. These are designated as W-B-131 and are contained in section 4, part 5 of the Federal Standard Stock Catalog.

The past twelve months have witnessed a considerable decline in the demand for primary battery products in general due to the business depression and the reduction in the number of battery operated radio sets in active use. This has naturally affected most the production of B batteries, though the production of 6-in. dry cells, many of which were also used for radio, has been seriously affected as well. The demand for flashlight batteries seems actually to be on the increase due perhaps to the appearance on the market of a rather wide variety and a considerable number of inexpensive flashlight cases which have apparently been widely bought.

The general decrease in demand for battery products has resulted in a tendency to reduce prices and on the part of at least the larger manufacturers to strengthen quality. Many of the smaller manufacturers have been forced out of the business as a natural consequence.

The year has brought the development of the industrial flashlight battery intended for use by public service corporations, railroads, theaters, and manufacturing organizations where the demand on the battery is considerably heavier than in ordinary flashlight use. At a recent conference at the Bureau of Standards two tests were standardized as representative of the industrial types of service and this has greatly facilitated and intelligently guided the development of satisfactory cells for this specific application.

Special radio B batteries of superior performance have been developed in response to demand created by radio-equipped automobiles for police squad use as well as for privately owned machines.

In the 6-in. dry cell group there has been a further advance in the life of the better telephone cells. Certain makes have reached the remarkably high figure of 360 days on the standard light intermittent test which compares with a maximum of about 180 days ten years ago.

An interesting new development which has occurred in the primary battery field during the past year is the introduction by one manufacturer of an air depolarized portable caustic soda battery designed primarily for use as an A battery for specially designed radio receivers using the new two-volt tubes and operated entirely by batteries. It is hoped that radio receivers of this type will develop wide application in rural districts where power is not available for operating electric radio sets and where storage batteries cannot be conveniently charged. This so-called air cell radio A battery is said to be good for a year's average service with one of these receivers. The basis of its operation is the absorption by a porous carbon electrode of the oxygen from the air which is carried to the surface of the electrolyte where it acts as a depolarizer for the cell. While the principle employed is not a new one, its application to a portable practical battery is believed to be new.

During the year, the revised American Standard for Dry Cells has been published, both by the American Standards Association of 29 West 39th Street, New York City, and by the Bureau of Standards in its Circular No. 390.

In the field of storage batteries the recent publication of the Federal Specification for Automotive Batteries, designated as W-B-131, may be mentioned.

A new storage battery, the Drumm alkaline cell, which involves the use of an electrolyte of potassium hydroxide with electrodes of nickel and other substances not disclosed, is said to provide reduced weight, increased efficiency, and the possibility of recharging in a 30 minute period. The e. m. f. is 1.5 volts. Successful trials in heavy trucking service are reported from England.

Electric Melting Furnaces

The demand for better metallurgical performance of arc furnaces is bringing about refinements in control gear among which are the use of tap-changing transformers to enable more precise voltage control and a tendency toward the adoption of hydraulic drive for electrodes, in which pilot valves responsive to furnace current, voltage or kva. operate to control fluid flow to the electrode driving cylinders. More prompt response, improved sensitivity and absence of hunting are said to be provided by hydraulic operation.

Induction furnaces of the submerged ring type are finding somewhat wider application owing to improvements in refractories and in a few places abroad have been used on high-nickel alloys and for superheating cast iron for high-strength castings.

Coreless induction furnaces operating at high frequency have found commercial application in sizes up to two tons, with power ratings up to 600 kw. High-frequency generating units of 1,250 kw. are being built to supply 3½ ton furnaces. A common frequency is 980 cycles, but the trend is downward, particularly for large units. Commercial frequencies have been successfully applied and one manufacturer has successfully operated experimental four-ton units at 60 cycles, the entire kva. requirement being supplied by a motor-generator set. Considerable attention has been given to the technique of refining in these induction furnaces and some success has been attained.

Oxygen-free copper from large inductively heated furnaces is a commercial possibility of the near future. Such a material would avoid some of the weaknesses of present commercial copper and in particular its tendency to embrittlement when subject to hot reducing gases. Unusually high ductility may make it interesting for some mechanical uses.

Control of furnace atmosphere, vacuum melting, and the distillation of metals are all receiving attention at the hand of investigators.

Water Purification

Electrolytic purification of water has been receiving considerable attention following the announcement, in Germany, of a process and apparatus in which water is passed through a succession of diaphram type electrolytic cells which cause concentration of ionogens in the electrode compartments. It is susceptible of large-scale operation but so far has been used mainly to complete the purification of distilled water.

Sterilization of Milk

The electropure process of milk conditioning effects pasteurization by passing the raw milk rapidly between carbon electrodes where it is heated by the passage of 60-cycle current. This scheme enables refinements in the control of the time and temperature variables that have hitherto been impracticable and the quality and uniformity of the product are thereby enhanced.

Electrostatic Precipitation

The results of test of improved hot-cathode vacuum rectifiers indicate that it will be possible to improve the operation and decrease the physical dimensions of the electrical end of precipitation plant. Increased use of powdered coal firing has caused the ash which is carried up the stack to be troublesome and electrostatic precipitator equipment is finding application in this connection. The same fundamental ideas are being applied to the separation of suspended solids from liquids. The purification of insulating oils is a case in point and it is stated that by electrostatic cleaning higher breakdown values can be obtained than by methods now in general use.

Metal Powders

Finely divided metals find numerous uses in chemical technology and as pigment in the decorative arts. Electrolytic means have been developed for producing copper, tin, nickel, silver, and lead in crystalline form in sizes as fine as 500 mesh.

MISCELLANEOUS PROCESS AND PLANT

Mercury-Arc Rectifiers

There are under construction for a Canadian Plant mercury-arc rectifiers rated at 6,500 kw. each (10,000 amperes, 650 volts) to be used for the electrolytic production of hydrogen.

Rotary Converters

Another electro-chemical plant has installed synchronous converters with load ratio control type transformers to furnish direct current for an electrolytic process. These machines are rated at 5,440 kw. each (16,000 amperes, 340/370 volts). These machines are also of interest because of their use of volute housings as part of the ventilation system.

Electrodeposition of Tungsten

The electrodeposition of tungsten in the wet way from alkaline baths has been accomplished on a laboratory scale. Tungsten possesses such marked resistance to acid attack and to wear that this development may prove to be of considerable industrial importance.

Heat Treating Furnaces

A marked interest was shown by the steel industry in the use of electric furnaces for heat treatment service. One plant installed two 1,100-kw. resistor type furnaces 50 tons capacity each, one 1,000-kw. similar furnace, and other furnaces, making a total of 4,500 kw.

The use of artificial atmospheres in electric furnaces for heat treatment processes is making considerable progress. One steel plant has installed 2,000 kw. in furnace capacity for bright annealing of steel strip.

Electrically heated and controlled apparatus for controlling the composition of the gases used are coming into evidence.

The special requirements of the nitriding process which involves heating to approximately 550 deg. cent. articles of special alloy steel (containing small amounts of Cr, Al, Mo, and Ni) in an atmosphere of ammonia has led to the development of furnaces with special provisions for circulating the ammonia. Heat transfer is effected by forced convection instead of by radiation. It appears possible that the application of this principle will find extended application in special-purpose furnaces in which control of atmosphere is important.

In both the heat-treating and melting fields the refinements of metallurgical technique and the growing recognition of the value of high quality and uniformity of product have brought about such profound changes in the design and operation of furnaces that they are coming to resemble machine tools rather than the piles of brick that the word usually calls to mind.

CONCLUSIONS

It is believed that this report reflects the more important trends in electrical process technology and hoped that it may draw the attention of electrically trained men to the very interesting possibilities in the field of the development of processes and materials dependent upon the forces that only electricity can bring into play.

The Chairman wishes to acknowledge the assistance given by members of the Committee and by numerous individuals in the preparation of this report which is respectfully submitted on behalf of the Committee on Electrochemistry and Electrometallurgy.

Electrophysics

ANNUAL REPORT OF THE COMMITTEE ON ELECTROPHYSICS*

THE annual report of the Committee on Electrophysics has generally taken the form of an account of the progress in the field of electrophysics during the preceding year. In view of the steady increase of the activity in this field the matter to be covered has increased greatly, and the report for the year 1929-1930 was a lengthy one in spite of all efforts to keep its size down to a minimum.

At a meeting of the committee held January 30, 1931 its field of activity and in particular its annual report were discussed at considerable length. It was the sense of the committee that it was one of the most important of its functions to bring to the attention of electrical engineers the progress being made in electrophysics. It was felt very strongly, however, that this cannot be done in the best possible fashion by reporting the progress for a year at one time and publishing it as a unit. Accordingly, the committee decided that it could be of much greater service to the engineering profession if its reviews of the progress in electrophysics were published from time to time by subjects instead of annually as a unit. As a result the plan was adopted of publishing reviews of the progress of electrophysics by subjects in ELECTRICAL ENGINEERING. Each contribution will aim to cover the progress in its particular field from the date of the preceding report as nearly up to the date of publication as is possible. A tentative schedule of the proposed subjects is as follows:

Magnetism and Magnetic Materials.
Propagation of Electric Waves.
Electric Discharges in Gases.
Dielectrics.
Thermionics and Photoelectricity.
Vacuum Gas Discharge and Photoelectric Tubes.
Electric Conduction in Solids.
Electromagnetic Theory.

In addition the Committee plans to sponsor from time to time for publication in ELECTRICAL ENGINEERING papers by recognized authorities on various subjects in electrophysics of interest to electrical engineers. One such paper is published herewith. After all the reviews for any one year have been published, they may be collected and published together in the TRANSACTIONS if it should be considered desirable.

Magnetism and Magnetic Materials

The following review of progress in magnetism and magnetic materials covers the period since the last report of the Electrophysics Committee. The progress in other phases of electrophysics will be covered similarly in succeeding reviews. The Committee also may offer from time to time papers on subjects in electrophysics of interest to electrical engineers.

MAGNETISM

Our understanding of ferromagnetism has advanced during the period since our last report (JL. A. I. E. E. 49, 721, 1930) in several important respects. Heisenberg's interaction theory, which refers the stability of magnetization to the low potential energy of codirected electron spins in neighboring atoms, has been applied by Powell (*Proc. Phys. Soc.* 42, 390, 1930) to explain the change in dimensions which take place when iron and nickel lose their ferromagnetism on heating. This change, a decrease in the case of iron, an increase in the case of nickel, is isotropic, being thus wholly unlike the principal part of magnetostriction which differs greatly in different crystallographic directions. It is concluded from the fact that both signs of change occur that some account must be taken, at least in the case of iron and probably in all cases, of atoms more remote than the immediate neighbors. Becker and Kirsten (*Zeitsch. f. Physik* 64, 660, 1930) who identify the stabilizing forces with internal elastic strains, have succeeded in getting rather good agreement between the permeability of highly stressed nickel as measured and as calculated from limiting magnetostriction and the elastic moduli. Rankin (*J. Roy. Tech. Coll.* Glasgow 2, 385, 1931) has continued his experiments on magnetostriction in overstrained metals. Akulov has continued his discussions of the relations between magnetostriction, magneto-resistance and elasticity concluding in his latest papers (*Zeitsch. f. Physik* 67, 794, 1931; *Phys. Zeits.* 32, 107, 1931) that the magnetic behavior of single crystals is fully explained by a dual process of reversals and rotations of the magnetic elements and that the magnetic properties of polycrystalline metal *without large scale anisotropy* can be calculated from data obtained for monocrystals. McKeehan (*Rev. Mod. Phys.* 2, 477, 1930; 3, 190, 1931) has reviewed the content and relations between the current theories of ferromagnetism and some of the recent experimental evidence pertinent thereto.

Several papers, in addition to that of Powell, already referred to, deal with the experimental and theoretical

aspects of the Curie point. Tyler (*Phil. Mag.* [7] **11**, 596, 1931) shows that the decrease of apparent saturation values with rise of temperature is practically according to the same law for iron, cobalt, and nickel, and that this is consistent with the idea that in all three metals single spinning electrons are free to change their axial direction, although in all these cases the average number of such magnetizable electrons per atom is greater than one. According to these data, therefore the ferromagnetic unit is sub-atomic rather than atomic. Above the Curie point it appears (Stoner, *Phil. Mag.* [7] **10**, 27, 1930) that atoms begin to act as units. Forrer and Hoffmann (*Comptes Rendus* **191**, 1046, 1930) present new evidence for a doubling of the (ferromagnetic) Curie point in nickel, the coercive force first decreasing, then increasing, and finally decreasing again as the temperature rises. An apparent disagreement between two experimenters, Weiss and Bates, in regard to the temperature at which the specific heat anomaly becomes greatest as the Curie point is approached has been dissolved by new evidence. Bates (*Proc. Phys. Soc.* **42**, 441, 1930; **43**, 87, 1931) now also finds this temperature to be where $-dI^2/dT$ is maximum; his earlier experiments were vitiated by an irreversible change in the properties of his material (manganese arsenide) produced by the small rise in temperature (magneto-caloric effect) associated with applying the magnetizing field. Incidentally, the specific heat anomaly is here far too large to be ascribed to an elementary magnet like that in iron or nickel.

The anomalous temperature coefficient of electrical resistance for ferromagnetics near their Curie points is closely associated with their magnetizability. Gerlach (*Zeitsch. f. Physik* **59**, 847, 1930; *Ann. der Physik* [5] **6**, 772, 1930) and Borelius (*Ann. der Physik* [5] **8**, 261, 1931) present opposing opinions regarding the anomaly. The former in agreement with earlier work of Cabrera regards the high-temperature state (above the Curie point) as normal and the low-temperature state as possessing an abnormally low resistance, the latter supports the contrary view that it is the low-temperature or completely magnetized state which has normal resistance. The transition as the Curie Point is approached from below is the same whichever view is taken.

The closely related subject of heat production during magnetization and demagnetization has been examined in a preliminary way by Gilbert (*Comptes Rendus* **191**, 1309, 1930) who finds no cooling in cobalt steel at H up to 18,000 except that attributable to the magneto-caloric effect of Weiss. The more complete report of Ellwood's results (*Phys. Rev.* [2] **36**, 1066, 1930) confirms his earlier finding of a cooling in carbon steel at low values of H on the ascending branch of a loop, and announces a second stage of cooling at moderate values of H. It should be noted that the magneto-caloric effect would account only for a minute heating in this part of the loop.

An effort has been made by Bitter (*Phys. Rev.* [2] **37**, 91, 1931) to coordinate ferromagnetic behavior with the small scale imperfection of metallic crystals recently predicted by Zwicky (*Helvetica Physica Acta* **3**, 269, 466, 1930; **4**, 49, 1931). Frenkel and Dorfman (*Nature* **126**, 274, 1930) deal with the same problem on purely thermodynamic principles, deciding that a large crystal cannot act as a magnetic unit.

Experiments on the Barkhausen effect in a rotating magnetic field (Cisman, *Ann. der Physik* [5] **6**, 825, 1930), make it more plausible than ever to suppose that the occurrence of a discontinuity in magnetization requires a definite degree of divergence between the applied field and the local magnetization. There is, in fact, a decided parallelism between Cisman's Barkhausen effects and hysteresis in rotating fields, most recently studied by Seiyama (*Mem. Kyushu Univ. Coll. Engg.* **5**, 227, 1930). Heaps and Bryan (*Phys. Rev.* [2] **36**, 326, 1930) have shown that large changes in magnetization and in magnetostriction are simultaneous. Bozorth has just discovered (*Nature* **127**, xxx, 1931) that in a very slowly changing magnetic field the Barkhausen discontinuities which can be detected by a high-speed oscillograph occur in closely grouped sets with quiet intervals between them. These compound events, in proximate analysis, can easily be mistaken for single events. This apparently explains the wide disagreement between published statements as to the volume of metal affected in a single discontinuity. The time required for the spreading of a major magnetic disturbance has been studied by Sixtus and Tonks (*Phys. Rev.* [2] **36**, 1441, 1930).

The gyromagnetic effect, hitherto only observed in ferromagnetic materials—most recently by Barnett (*Phys. Rev.* [2] **36**, 789, 1930)—has now been measured for a paramagnetic material by Sucksmith (*Proc. Roy. Soc.* [*A*] **128**, 276, 1930; *Proc. Phys. Soc.* **42**, 385, 1930). The phenomenon is merely easier to observe in ferromagnetics on account of their easier magnetization.

In studies on diamagnetic and weakly paramagnetic metals the theory has been improved by Landau (*Zeitsch. f. Physik* **64**, 629, 1930) and Teller (*Zeitsch. f. Physik* **67**, 311, 1931) so that better predictions are now possible as to the diamagnetism to be expected from conduction electrons. On the experimental side relatively enormous changes in susceptibility—much larger than the changes in conductivity make probable—have been reported by Honda and Shimizu (*Nature* **126**, 990, 1927) and by Bitter (*Phys. Rev.* [2] **36**, 978, 1930), both of whom measured the susceptibility of copper as affected by cold work and annealing. Banta (*Phys. Rev.* [2] **37**, 634, 1931) has attempted without success to duplicate Bitter's findings.

Spectroscopic evidence that some atomic nuclei have a small magnetic moment continues to accumulate (Fermi, *Zeitsch. f. Physik* **60**, 320, 1930; Goudsmit and Young, *Phys. Rev.* [2] **35**, 1418, 1930; Frisch and Ferchmin, *Naturwiss*, **18**, 866, 1930). The effect upon gross magnetic properties of such nuclear magnetic moments as have yet been shown to exist must be very small.

Effects of magnetic fields on electrical resistance and electric potential with or without the presence of thermal currents and temperature differences have been reviewed on the basis of the new electron theory of metals by Sommerfeld and Frank (*Rev. Mod. Phys.* **3**, 1, 1931). The proper mode of description of these galvanoelectric, thermoelectric, galvanomagnetic and thermomagnetic effects have been discussed by Perrier (*Helvetica Physica Acta* **3**, 317, 400, 1930). The conditions are especially complicated in the case of ferromagnetics. Pugh (*Phys. Rev.* [2] **36**, 1503, 1930) has shown for iron that the magnetization, I, or the ferromagnetic induction, B-H, is more important than either H or B in fixing the magnitude of the Hall e. m. f. Stierstadt (*Zeitsch. f. Physik* **65**, 575, 1930; **67**, 725, 1931) has studied magneto-resistance in electrolytic iron for both longitudinal and transverse magnetizations. Williams and Sanderson (*Phys. Rev.* [2] **37**, 309, 1931) present new data on magneto-resistance in nickel strips of different mechanical history.

The magneto-resistance of bismuth single crystals at extremely low temperatures, below 20 deg. K, has been studied in detail by Schubnikow and de Haas (*Nature* **126**, 500, 1930; *Proc. Amsterdam Acad.* **33**, 363, 418, 1930), who find a whole series of unexpected phenomena. Unlike the magneto-resistance at higher temperatures the relative change in resistance is no longer a smoothly varying function of the applied field, H, nor of the azimuth in any crystallographic plane yet examined. At higher temperatures, however, theory has caught up with experiment, for Frank (*Zeitsch. f. Physik* **64**, 650, 1930) has shown that the straightening out of $\Delta R/R$ *vs.* H curves at high H values, first observed by Kapitza, is completely accounted for by the quantum theory of electronic conduction. The parabolic increase of $\Delta R/R$, formerly supposed to be called for by the theory, is only possible for relatively limited ranges in H.

One of the most puzzling experimental results recently published is that of Allison and Murphy (*Am. Chem. Soc. Jl.*, **52**, 3796, 1930), who report that the magnetic double refraction (Faraday Effect) in certain solutions is characteristic, not only of the elements present but even of the number of isotopes of each, and furnishes a highly sensitive means for chemical analysis.

In the domain of magnetometry Sanford has been investigating magnetic permeameters, particularly those for use at high inductions (*Bu. Std. J. Res.* **4**, 177, 703, 1930; **6**, 355, 1931). A new level of precision in magnetic curve tracing has been attained by Haworth (*Bell System Tech. Jl.* **10**, 20, 1931; *Rev. Scient. Instr.* [N. S.] **2**, 125, 1931) who compensates the torque of a fluxmeter suspension by a photoelectric current depending upon the momentary deflection. Brüche (*Zeitsch. f. tech. Physik* **12**, 94, 1931) has considerably refined the methods for exploring magnetic fields by narrow beams of cathode rays. Freed and Kasper (*Phys. Rev.* [2] **36**, 1002, 1930) have improved the accuracy of Gouy's method for measuring the susceptibility of weakly magnetic solutions.

A stimulating book by S. R. Williams[1] gives a readable account of the experimental side of the subject of magnetism, with especial emphasis on ferromagnetism.

An important announcement regarding magnetic units as adopted by the International Electrotechnical Commission was made by Dr. Kennelly at the Winter Convention in New York. The electrophysics committee is by no means unanimously in accord with the suggestions of the international body. Some of our members feel that the already existing confusion in regard to the physical significance of B and H is increased rather than diminished by giving physical dimensions to their ratio. It is interesting to notice that a body of German engineers went even farther than the I. E. C. in the effort to rationalize empirical relations (*Elektrotech. u. Maschinenbau* **48**, 950, 1930).

MAGNETIC MATERIALS

The results of many investigations carried out in the past three or four years confirm the view that crystal grain size is one of the important factors in magnetic materials. Yensen (*Metals and Alloys*, **1**, 493-495; 1930) has proposed an expression for the hysteresis loss in iron in terms of the crystal grain size and impurities in the metal, leading to the conclusion that for perfect single crystals, free from impurities and internal strain, the hysteresis loss vanishes. Gerlach has more recently arrived at a similar conclusion. (*Zeitsch. f. Physik*, **64**, 502-506; 1930). On the other hand Von Auwers and Sizoo (*Zeitsch. f. Physik*, **60**, 576-580; 1930) conclude that crystal grain size has much less influence on remanence than on hysteresis loss and coercive force.

What promises to be of great importance is the announcement by Cioffi (*Nature*, **126**, 200-201; 1930) that ordinary polycrystalline iron may be made to acquire very high permeability by heat treating at high temperature in hydrogen. The reported initial and maximum permeabilities are 6,000 and 130,000, respectively, and the coercive force and hysteresis loss are respectively 0.05 gauss and 300 ergs/cu. cm./cycle, for $B_m = 14{,}000$. Later unpublished values give 180,000 for the maximum permeability, 0.025 gauss for the coercive force and 190 ergs/cu. cm./cycle for the hysteresis loss for the same maximum induction. These properties are ascribed partly to purification of the iron and partly to the hydrogen actually absorbed in the metal. Further correlation appears to be necessary between crystal grain size and magnetic properties in view of these results, since the grain size of this material appears to be of little importance.

The existence of the A_3 point in carefully purified iron occurring reversibly between 907 deg. cent. and

---

[1] "Magnetic Phenomena," McGraw-Hill, 1931.

910 deg. cent. has been confirmed by Roberts and Davey (*Metals and Alloys* **1**, 648-654; 1930), by X-ray crystallographic determinations. This fact has recently been a matter of some dispute (Yensen, A. I. M. & M. E., *Inst. Metals Div.*, 320-332; disc. 332-349; 1929).

The increasing importance of nitrided steels has led to further investigations of the iron-nitrogen system. Qualitative and quantitative measurements by Lehrer (*Zeitschr. f. Electrochem.*, **36**, 460-473; 1930) by means of magnetization-temperature curves have been used to construct the equilibrium diagram for the iron-nitrogen system. The results show that up to 11 per cent nitrogen there are four phases, in agreement with the X-ray determinations of Hägg (*Zeitsch. f. Physik. Chem.* **8**, 455-474; 1930) and Eisenhut and Kaupp (*Zeitschr. f. Electrochem.* **36**, 392-404; 1930). Köster (*Archiv. f. Eisenhüttenwesen* **3**, 637-648; 1930) has shown that nitrogen in α-iron remains in supersaturated solution even after slow cooling, requiring prolonged heating at low temperatures for complete separation, with a resultant increase in conductivity and increase in coercive force from 4 to 7 gauss. The segregation of nitrogen in the supersaturated solution is further accelerated by cold working (*Archiv f. Eisenhüttenwesen*, **3**, 649-658; 1930).

A number of alloys of iron and non-magnetic elements has been investigated. Pure electrolytic iron having a trace of phosphorus has been found to have better magnetic properties than commercial silicon steel. (*Gayler, Metallwirtschaft*, **9**, 677-679; 1930.) The iron-silicon system has been studied by Haughton and Becker, (*Iron and Steel Inst. Jl.*, **121**, 315-335; 1930) using metals of higher purity than heretofore. The existence of phases corresponding to the compounds FeSi, and Fe_3Si_2 have been confirmed, and in addition a phase which is probably the compound Fe_2Si_5. The addition of 14.5 per cent silicon lowers the Curie point of iron to 490 deg. cent. A magnetic transformation point occurring at 82 deg. cent. in the Fe_3Si_2 phase confirms the earlier work of Murakami (*Tohoku Imp. Univ. Sci. Rep.*, **10**, 79-92, 1921). Oya (*Tohoku Imp. Univ. Sci. Rep.* **19**, 235-245; 1930) has found that additions of vanadium to iron first raise the Curie point then depress it, so that it is room temperature for 35 per cent vanadium. The alloys of iron and chromium with approximately 18 per cent chromium have been found to have zero magnetostriction (Dean, *Rensselaer Polytech. Inst. Bull. No. 26,* Eng. and Sci. Series; 1930). Fischer (*Rensselaer Polytech. Inst. Bull. No. 28*, Eng. & Sci. Series; 1930) has found that this range of alloys has higher permeability and is less sensitive to quenching strains than other alloys of this group. This behavior has already been observed in permalloy (Buckley and McKeehan, **26**, 261-273; 1925) and is in accordance with McKeehan's theory of magnetostriction (*Phys. Rev.* **28**, 158-166; 1926). Kussmann, Scharnow, and Messkin (*Stahl u. Eisen*, **50**, 1194-1197; 1930) have found that additions of copper up to 0.7 per cent increase the resistance of iron to corrosion without impairing its magnetic and electrical properties. A general deterioration of these properties is obtained for higher copper concentrations.

The relation of magnetic properties to mechanical hardness has been investigated by Messkin (*Stahl u. Eisen*, **50**, 105-106; 1930) who has found that cold rolling increases the remanence and coercive force of carbon steel; and by Herbert (*Proc. Roy. Soc.*, **130**, 514-523; 1930) who has observed age hardening of steel and non-magnetic metals subjected to a changing magnetic field.

Sachse and Hasse have found that (*Zeitsch. f. Physik Chem.*, [A] **148**, 401-412; 1930) regular crystals of ferromagnetic ferric oxide, Fe_2O_3, are unstable at all temperatures, the susceptibility falling by 60 per cent in 4 years at room temperature. The fact that ferric oxide has 10^{-10} the conductivity of the ferromagnetic metals, leads Sachse (*Zeitsch. f. Phys. Chem.*, [B] **9**, 83-91; 1930) to conclude that free electrons cannot be concerned in its magnetic properties. The ferrites of magnesium, lead, copper, and nickel are also ferromagnetic at ordinary temperatures, cadmium ferrite being sometimes ferromagnetic and sometimes paramagnetic (Holgersson and Serres, *Comptes Rendus*, **191**, 35-37; 1930). In mixtures of Fe_2O_3, NiO, and C_0O, Veil (*Comptes Rendus*, **190**, 181-183; 1930) has found a higher coefficient of magnetization for the composition represented by $(Fe_2O_3)_2$ $NiOC_0O$.

A somewhat higher Curie point has been obtained for nickel by Jordan and Swanger (*Bur. Std. Jl. of Res.* **5**, 1291-1307; 1930) which is believed to be due to the greater purity of their nickel specimen. Sadron has found that (*Comptes Rendus*, **190**, 1339-1340; 1930) small additions of chromium to nickel, causes the saturation value at absolute zero to diminish linearly with chromium content, the Curie point for an alloy with 12 per cent Cr being absolute zero.

Widespread interest in the nickel-iron alloys coming under the collective name of permalloy is indicated by its numerous modifications to meet specific needs. Elmen has obtained very high initial permeability and resistivity in nickel-iron alloys by additions of molybdenum, chromium or tungsten (U. S. Pat. 1,757,178; *Jl. Frank. Inst.* **207**, 583-618; 1929). Stäblein (U. S. Pat. 1,760,326) has obtained high resistivity by additions of silicon. Bandur (U. S. Pat. 1,743,089) and Yensen (*Elec. Jl.* **27**, 214-218; 1930) report that with suitable heat treatment some nickel-iron alloys may be made to acquire sensibly constant permeability over a limited range of induction. Similarly, Smith and Garnett (U. S. Pat. 1,746,500) have obtained substantially constant permeability in nickel-iron alloys by additions of copper. Also, Gumlich, Steinhaus, Kussmann and Scharnow (*E. N. T.*, **7**, 231-235; 1930) report that high resistivity and small variation of permeability with magnetizing force are obtained in nickel-iron alloys by small additions of manganese.

Von Auwers, (*Wiss. Veroffentlich Siemens-Konzern* **9**, 262-293; 1930) has studied the effect of strain on the magnetic properties of permalloy. The results of numerous experiments indicate that the properties of permalloy cannot be accounted for on the basis of strain alone.

Methods of design and testing of permanent magnets have kept abreast with the improvements in magnetic properties. Elenbaas (*Physica,* **10**, 273-286; 1930) has derived a formula for calculating the field intensity in a toroid with an air-gap, based on the assumption that the demagnetization curve is an ellipse; this should prove useful in the design of permanent magnets. It is well known that the magnetization of a ferromagnetic material by a steady field is considerably increased by the superposition of an alternating field. Schrankow and Janowsky (*Zeitsch. f. tech. Physik* **11**, 429-432, 1930) apply this method of bringing permanent magnets to high inductions. An accurate method of testing bent permanent magnets has been described by Webb and Ford (*I. E. E. Jl.,* **68**, 773-778; 1930) whereby both B and H are measured by means of search coils and a ballistic galvanometer. The superior properties of cobalt-steel as permanent magnets have found application in the magnetic compass for aircraft, disturbances from stray magnetic fields being avoided by shielding with hipernik, a nickel-iron alloy of high permeability (J. R. Gier, *Elec. Jl.,* **27**, 114-115; 1930).

The need for accurate and constant substandards of frequency has stimulated further work on vacuum tube oscillators controlled by the resonant magnetostrictive vibrations of magnetic materials. This method of control requires the use of materials which have good magnetostrictive properties and small temperature coefficients of permeability and expansion. Vincent (*Proc. Phys. Soc.* **43**, 157-165; 1931) has extended the range of the magnetostriction oscillator of Pierce, (*Proc. Am. Acad. Sci.,* **63**, 1-47; 1928) to radio frequencies by using corronil, a nickel-copper-manganese alloy, and glowray, a nickel-iron-chromium alloy (*Proc. Phys. Soc.* **41**, 476-486; 1929); the latter, particularly, has a high degree of stability. Smith (*Proc. Phys. Soc.* **42**, 181-189; 1930) has determined the nature and magnitude of the coupling between the mechanical vibrator and the electric circuit for a toroidal specimen of a nickel-iron alloy vibrating radially in its fundamental mode. Muzzey (*Phys. Rev.* **36**, 935-947; 1930) has used the magnetostriction oscillator as a means of exciting cylinders of stainless steel in studying the dependency of frequency of vibration on length and diameter of the cylinders.

ACKNOWLEDGMENT

The Committee is indebted to Professor L. W. McKeehan, of its membership, and to Mr. P. P. Cioffi for material for this report.

General Power Applications

ANNUAL REPORT OF COMMITTEE ON GENERAL POWER APPLICATIONS*

THE principal activity of the Committee during the past year has been in arranging and carrying out of plans for the Industrial Session held at the Winter Convention. As this Committee is interested in the application of electricity to all industries which are not specifically covered by other committees of the Institute, it was agreed that papers to be of interest to the greatest number of engineers should be of a general nature and not confined to a specific industry or application. The papers presented were consequently arranged and prepared with this thought in mind. During this period of industrial depression an increasing amount of attention is being given to the subject of reducing manufacturing costs and it was hoped that industrial engineers would find in these papers various ideas which could be applied to their own problems.

INDUSTRIAL PAPERS PRESENTED

Besides those papers presented at the Winter Convention several other papers of an industrial nature were presented at district meetings. Following is a list of those papers which have come to our attention:

Philadelphia Meeting Oct. 13 to 15, 1930:

Air Conditioning in Industry, by A. H. Clogston of the Cooling and Air Conditioning Corp.

A New System of Speed Control—A-C. Motor-Driven Power Station Auxiliaries, by A. M. Rossman of Sargent and Lundy, Inc.

Louisville Meeting, Nov. 19 to 22, 1930:

Electricity in the Cement Industry, by R. H. Rogers of the General Electric Company.

Electric Power in the Lumber Industry, by A. H. Onstad of Weyerhaeuser Timber Co.

Winter Convention, January 26 to 30, 1931:

Electron Tubes in Industry, by W. R. King of General Electric Co.

Automatic Regulators in Industry, by J. H. Ashbaugh, Westinghouse Electric and Manufacturing Co.

Electrical Distribution Systems for Industrial Plants, by W. J. McClain, of Louis T. Klauder Co.

The Synchronous Motor with Phase-Connected Damper Winding as a Drive for High-Torque Loads, by M. A. Hyde, Jr., Westinghouse Electric and Manufacturing Co.

The Design and Application of Synchronous Motors to Meet Special Requirements, by D. W. McLenegan and A. G. Ferriss of General Electric Co.

Pittsburgh Meeting, March 11 to 13, 1931:

Conversion and Distribution of General Purpose D-C. Power in Large Industrial Plants, by R. D. Abbiss, Carnegie Steel Co. and D. C. West, Westinghouse Electric and Manufacturing Co.

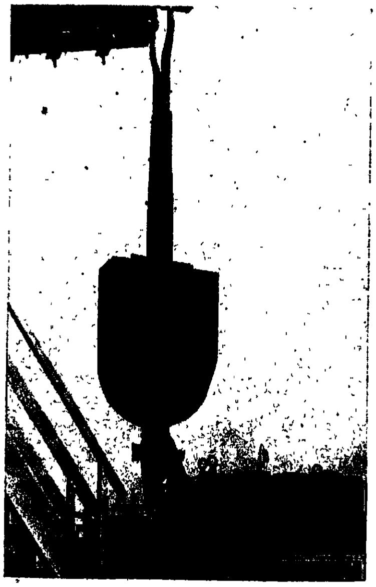

FIG. 1—COMBINATION PUMPING UNIT FOR OIL WELLS INCLUDING MOTOR, GEARS, AND CONTROL

Symposium on *Interconnection Between Utilities and Industries*. Several papers.

The Use of Electricity in Large Annealing Furnaces, by J. C. Woodson, Westinghouse Electric and Manufacturing Co.

A Modern Electrified Dairy Plant, by A. J. Dreux, Reick-McJunkin Dairy Co. and H. C. Brunner, Westinghouse Electric and Manufacturing Co.

REVIEW OF INDUSTRIAL PROGRESS

Since the past year has not been one of great industrial development or activity, it is felt that this report should include not only a review of the major industrial developments but also should indicate the trend of development along both application and apparatus lines in industry.

M. R. Woodward.

Petroleum Industry

During the past year pipe-line transportation of liquid fuel over long distances has been extended to include gasoline. Electric pumping stations supplied with central station service, are increasing in number and proving their economy. The latest development is an electric station with three 800-hp. pumping units which is completely controlled from a dispatching office about 15 miles away. This is the Sand Springs Station of the Texas Empire Pipe Line that connects Oklahoma oil fields with the Chicago refineries. The supervisory control permits the dispatcher to exercise complete control over the station and gives a visual indication of its operation. The dispatcher can tell at a glance what units are operating, what the intake and discharge pressures are and as much other pertinent information as could be obtained if the operator were in the station. In case of trouble the equipment is shut down automatically and the dispatcher advised of the nature of the trouble.

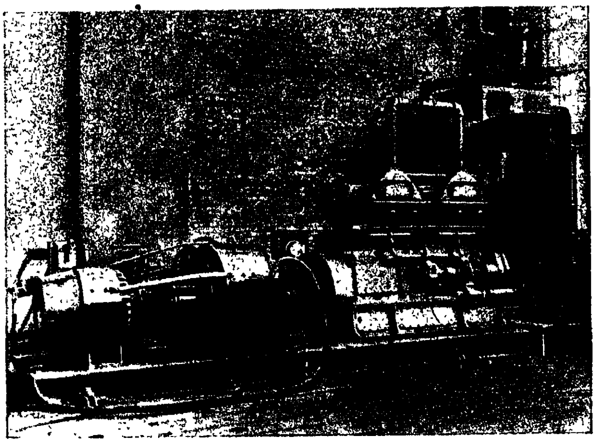

Fig. 2—Portable Diesel Engine-Driven Set for Variable Voltage Oil Well Drilling Outfits (Shop View)

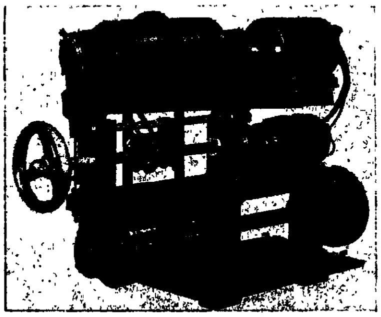

Fig. 3—Selsyn Generator and Cone Pulleys for Sectional Paper Machine Drive

Development in electrical oil field pumping and drilling equipment has been towards the use of combination, or factory assembled apparatus which eliminates many parts and reduces the installation expense in the field. One of the latest pumping units consists of a combination of gear, motor, and control built in one unit. The equipment is weatherproof and requires no housing. The unit is also provided with change gears for obtaining several speeds as required for various pumping conditions.

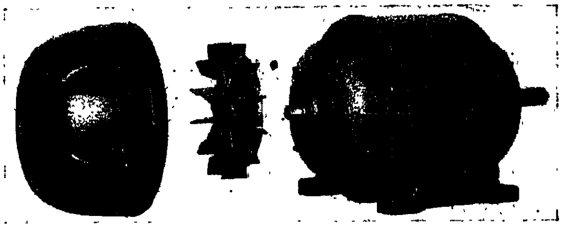

Fig. 4—Totally Enclosed Fan-Cooled Motor with Fan and Fan Casing Removed

During the past year several variable voltage d-c. oil well rotary drilling outfits have been built and put in service, using Diesel engines as prime movers. These outfits are being used primarily on locations where central station power is not available. The ease and simplicity of control obtainable with the variable voltage d-c. system, its low energy requirement and flexible operating characteristics, make this system very desirable for this type of oil service.

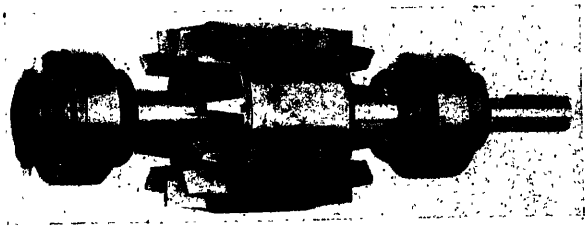

Fig. 5—Induction Motor Rotor Showing Cartridge Type Ball-Bearing Housings

Two installations are also reported where standard a-c. drilling equipments were installed and supplied with power from Diesel engine-driven generators, and, although this system may lack some of the desirable features of the variable voltage system, it makes it possible to use standard a-c. motors for pumping and other uses.

Pulp and Paper Industry

Sectional paper machine drives were installed during the year on a wide variety of machines from low-speed cylinder to high-speed fourdrinier and the use of section regulators of the carbon pile type instead of the contact making type was quite noticeable. A description of some of these carbon pile regulators is given in Mr. Ashbaugh's paper, presented at the Winter Convention.

A regulator for sectional drives using Selsyn equipment so that the main regulating equipment may be mounted remote from the paper machine has been placed in operation during the year. At the paper machine, in connection with each sectional motor, is a Selsyn generator driven through suitable cone pulleys which provide necessary speed adjustment or "draw" between the various sections. The resistance elements of the regulator are of the carbon pile type.

RURAL ELECTRIFICATION

The use of electricity on the farm has increased rapidly during the past year and reports from central stations indicate that approximately 90,000 farms were connected to their lines during the year. This represents an increase of 16 per cent over the total number previously connected. This growth is accounted for partly by the interest of the power companies in the farm load and partly by improved rate structures and power schedules. But of fully as great importance however is the increasing list of electrical equipment which is available and specially adapted for farm service. The attention being given to the production of milk with a low bacteria count has done much to force the installation of dairy sterilizing and dairy refrigerating equipment and these devices in connection with other dairy and household equipment make a very desirable electrical load.

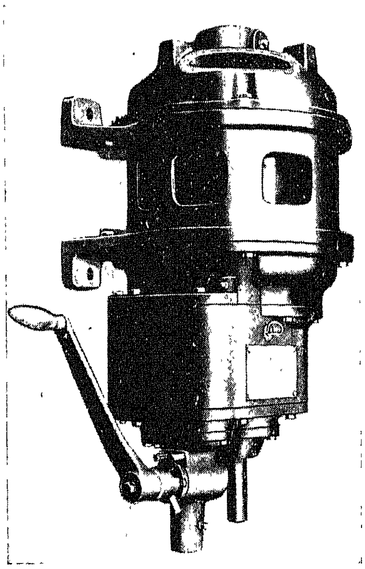

FIG. 6—MOTOR WITH BUILT-IN FOUR-SPEED TRANSMISSION SHOWING SPEED CHANGING LEVER

Engineering research and investigation have proven the possibility of using 5-hp. electric motors for practically all stationary work such as silo filling, feed grinding, wood sawing, etc., instead of using 15- or 20-hp. tractors. Numerous improvements have recently been made in the design and construction of portable motor equipment for such service which includes automatic linestarters with thermal overload protection, effective methods of belt tightening, and other desirable features.

FOOD PRODUCTS INDUSTRY

Although this industry has received but little attention from electrical engineers, it is the fourth greatest user of electric motors on the basis of connected horsepower. In addition to motors, electric energy is used for various other purposes as the production of ultraviolet rays to help preserve or increase the vitamin content of foods; photoelectric tubes for actuating operations of wrapping, sorting, and counting; cooking of foods by various electrical processes, and the pasteurization of milk.

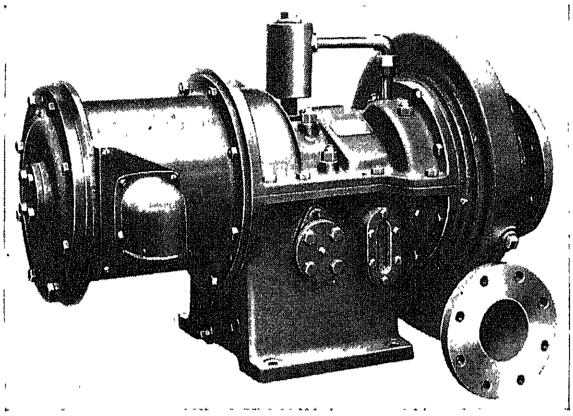

FIG. 7—GEARED CENTRIFUGAL REFRIGERATION COMPRESSOR DRIVEN BY TOTALLY-ENCLOSED INDUCTION MOTOR

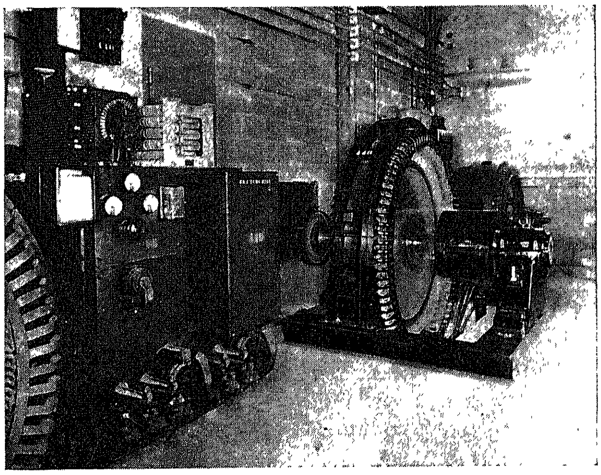

FIG. 8—300-HP. 164-REV. PER MIN. SYNCHRONOUS MOTOR OF THE PHASE-CONNECTED DAMPER TYPE AS INSTALLED IN A CEMENT PLANT

A paper on the subject of *A Modern Electrified Dairy Plant* was presented at the Pittsburgh District Meeting of the Institute March 11-13, 1931, by Mr. A. J. Dreux and Mr. H. C. Brunner. This paper illustrates how a modern electrified dairy offers a very desirable type of load for central stations, particularly when using the electrical conductivity method of pasteurization.

INDUCTION AND D-C. MOTORS

During the past year several new lines of induction motors have been placed on the market and the trend is toward simplification and standardization of design. The greater use of standardized parts reduces the stocks which must be carried both by the user and manufacturer, increases the number of combinations or types of motors possible with a given number of parts and in general makes the apparatus more universally adaptable.

Several new lines of totally enclosed fan-cooled squirrel-cage induction motors have been announced and in practically all cases these motors are on the same frame size as corresponding ratings of open motors. In these fan-cooled motors ball or roller bearings are used almost without exception and the cartridge type of bearing housing is quite generally adopted. This construction permits the dismantling of the motor and the removal of the rotor without exposing the bearings.

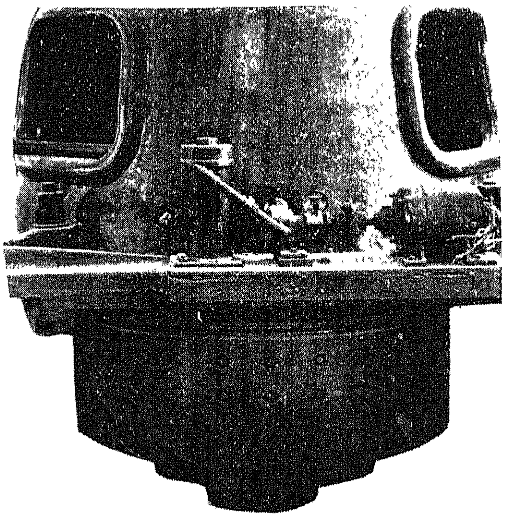

FIG. 9—SPECIAL SYNCHRONOUS MOTOR WITH EXTERNAL REVOLVING FIELD, DIRECT CONNECTED TO GYRATORY CRUSHER

A number of manufacturers has also brought out lines of totally enclosed fan-cooled motors for use in locations where explosive gases are present. These motors are approved by the Underwriters Laboratory for use in gasoline refining, garages, gasoline handling, and filling stations, dry cleaning establishments, chemical plants, paint factories, and in similar locations.

To meet the requirements of testing large vertical pumps and turbine wheels a vertical dynamometer rated at 300 hp. has been developed. The stator is supported in such a manner that it is free to rotate and the torque developed is measured on a beam and dial scale. The direct-current armature is especially constructed and makes use of a shrink-ring type commutator for high-speed operation.

Fractional horsepower motors of the universal commutator type have a wide speed range from no load to full load and consequently are not generally applicable for the constant speed service. A novel type of clutch has been developed which when installed in these fractional horsepower motors maintains a practically constant speed at the coupling regardless of how much higher the motor speed may go. This device consequently makes it possible to use universal motors for such applications as cash registers, calculating machines, small motor-generator sets, etc.

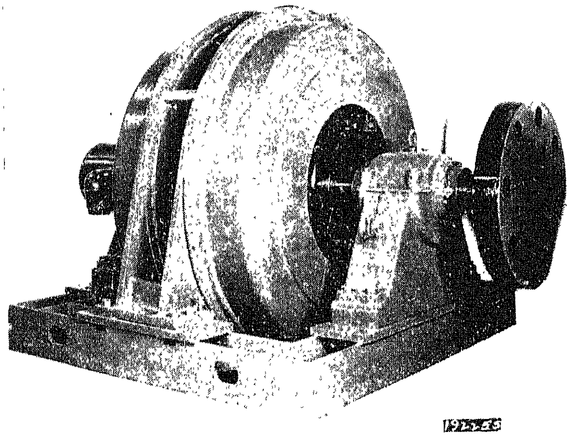

FIG. 10—250-HP., 450-REV. PER MIN. TOTALLY-ENCLOSED FAN-COOLED, SYNCHRONOUS MOTOR

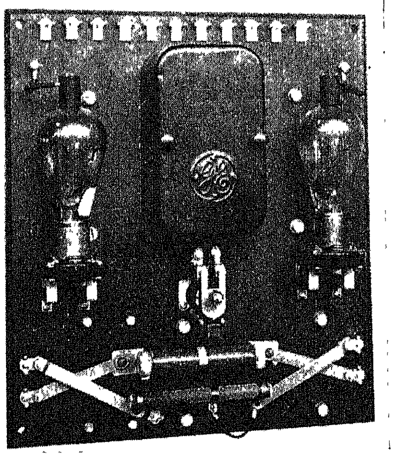

FIG. 11—ELECTRONIC TUBE CONTROL FOR SMALL D-C. MOTORS

Although speed reducers or gear reducers are now extensively used there is a decided trend towards the combination of various types of these gear reducers with industrial motors in order to form a more compact and self-contained unit. Some of these are of the fixed ratio type with either single, double, or triple reduction while others have a variable ratio. A recent addition consists of a standard constant speed motor in combination with a 4-speed gear forming a self-contained and very compact unit. With this combination various gear ratios are available and it is possible to change from one speed to another under full load conditions.

Another example of a combined unit is a centrifugal type compressor for refrigerating service in which the compressor, gears, and motor are combined in one unit. This is a high-speed single-stage compressor of approximately 25 tons refrigeration capacity and by means of the unit type construction it is possible to eliminate the usual shaft seals.

FIG. 12—SAMPLE CHART OBTAINED WITH SMOKE RECORDER

A paper presented by Mr. A. M. Rossman at the Philadelphia meeting *A New System of Speed Control for A-C. Motors*, gives a detailed account of a new method of speed control, its possibilities, and savings. The system consists essentially of a constant speed a-c. motor of either the synchronous or induction type, supplemented by an adjustable speed d-c. machine of much smaller size and a motor-generator set of similar capacity. The frame of the a-c. motor is mounted on bearings so that the frame as well as the rotor may rotate.

FIG. 13—CONSOLE TYPE BOARD FOR ELECTRONIC TUBE CONTROL OF THEATER LIGHTING AND DIMMING

SYNCHRONOUS MOTORS

At the Winter Convention two papers on the subject of synchronous motors were presented. The motor described by Mr. M. A. Hyde, Jr., was developed especially for low-speed applications requiring high starting and high pull-in torques with a low-current inrush. The damper construction instead of being of the usual squirrel-cage type is phase wound and in starting an external resistance is inserted in this circuit and the motor accelerates in a manner quite similar to that of the ordinary wound rotor induction motor.

The paper presented by Messrs. McLenegan and Ferriss discusses the design features of normal synchronous motors and shows how these features are varied to adapt synchronous motors to the requirements of various special applications. Among the various modifications discussed are the use of part-winding starting for applications where low-starting torques and low-starting inrush are desirable, also various methods of obtaining high-starting torque such as by means of over-sized motors, over-voltage, delta-Y starting, tapped windings, phase-connected damper windings for both salient and non-salient pole motors, and a rotable stator scheme.

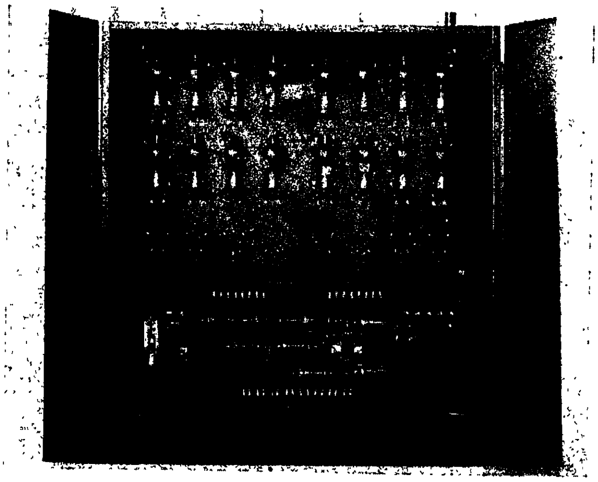

FIG. 14—ELECTRONIC TUBE CONTROL OF POLYCHROMATIC FLOOD-LIGHTING SYSTEM

It is reported that the first application of a synchronous motor directly connected to a grain elevator leg was made during 1930. Ordinarily the starting torque required by these legs or bucket elevators is comparatively light but in case of emergency such as starting after a power failure, with the buckets loaded, a high-starting torque and a high pull-in torque are required.

Although several high-torque synchronous motors have been applied to primary or large gyratory crushers most of these have been of the standard mechanical construction and usually belted to the crusher pulley. A unique application has been made which utilizes a vertical motor of the umbrella type in which the revolving field poles are external to the stator which in turn is bolted rigidly to the frame of the crusher.

Another interesting and rather unusual application of a synchronous motor is for driving a hot copper rolling mill which requires continuous reversing service. The motor is guaranteed to reverse in five seconds and a special type of damper winding construction is used to increase the radiating surface and dissipate heat caused by the frequent starting and stopping.

For use in the Chilean Nitrate Industry a number of synchronous motors rated at 250 hp., 450 r. p. m., was built of the totally enclosed fan-cooled type. This construction is necessary to protect the motors against the saline solutions and vapors and the construction details are along very much the same lines as carried out on the smaller industrial motors.

When protected type motors are required either on account of injurious vapors or dust, it is sometimes undesirable or impossible to locate the control equipment in separate rooms and to take care of those cases in which the control must be mounted in the same location as the motor, synchronous motor starters have been developed with the entire control immersed in a tank of oil.

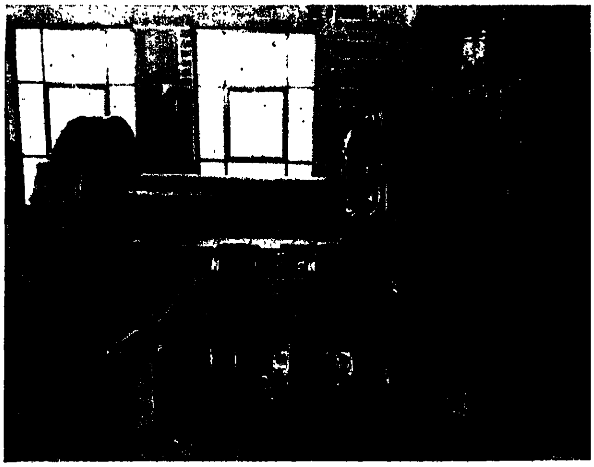

Fig. 15—Motor for Lower Elevator of Dual System with Combination Motor-Generator Set and Control Foreground

Electronic Tubes

During the past year the electronic tube has become an accepted industrial device. Its original use was confined to the arts of communication and science and not until recently has any concerted effort been made to apply it to industrial purposes. Electronic tubes possess characteristics not available in older forms of electrical apparatus but offer many possibilities for industrial applications. These characteristics may be listed briefly as follows: speed of operation, small actuating energy requirement, amplification properties, accurate response, quietness of operation, and freedom from moving parts and contacts. In addition, the actuation of electronic tubes may be brought about by a large number of different physical effects including changes in resistance, inductance, capacitance, phase angle, frequency, temperature, sound, light, color, radio or carrier current.

There has developed a demand for electronic tube units which can be adapted to many applications for experimental purposes. Such units have been brought out by several manufacturers. The more common of these are the photoelectric units and electrostatically controlled arc discharge units. The tubes used in the latter are better known by the trade names of grid glow or thyratron.

In line with this increasing interest a paper entitled *Electron Tubes in Industry,* was presented by Mr. W. R. King at the Winter Convention. This paper gives a general discussion of the theory and characteristics of electron tubes without going into design details or calculations. Several of the more common control schemes involving tubes are explained for the purpose of showing how tube characteristics can be adapted to various applications.

To eliminate the human element in determination of smoke density a device utilizing a light source and photoelectric tube in connection with a recording instrument has been developed and gives a continuous accurate record of smoke density. The light source is mounted on one side of the stack and throws a beam of light through an aperture on the photoelectric tube mounted on the opposite side. The amount of light reaching the photoelectric tube is determined by the smoke density, and indicating or recording instruments may be installed at any convenient location.

One of the most interesting and largest electron tube applications is the control of lighting for stages and auditoriums. Installations of this type involve the use of between 300 and 600 electron tubes. Three installations of this type are in the Civic Opera House in Chicago, the Severance Memorial Hall in Cleveland, and a theatre in Los Angeles. The latest of these units, the one at Cleveland, has all of the control circuits operated from an organ type console. With this control it is possible to pre-set scenes, gradually fade from scene to scene with either manual control or automatically at a pre-determined rate, and vary the intensity of any light circuit in the hall individually or in combination with any other circuit or circuits. In the old types of stage lighting control the intensity was varied by means of rheostats. This new method uses three-legged reactors located conveniently for load distribution and the degree of saturation and consequent change in light intensity is varied by rectified direct current from tubes. Another application for the same type of equipment as used for theatre dimming is the control of building flood lights. On a large number of new buildings the lighting is so arranged that the shading and colors vary in some regular cycle.

Electron tubes are also being used for speed control of d-c. motors in a number of various applications. At the present time for smaller motors, that is 3 hp. or below the control can be accomplished directly by control of armature voltage and current supplied from tubes, while for larger motors the field current only is controlled and supplied by tubes. One of the better known applications of this type is the maintaining of proper tension in the wire for a wire drawing machine and reel.

Photoelectric units have also been adapted to any number of production line applications where the objects are too light or fragile to operate ordinary control making or breaking devices by physical contact. On any application where an object can be made to intercept or otherwise vary a light beam this action can be used to actuate an operation. Some of the more common applications have been for counting, wrapping of packages such as foods, gum, etc., flag switches for reversing rolls as in steel mills, flashover protection of rotary converters, cutting of paper sheets to the proper length as required in connection with paper bag machines, paper break indicators in connection with paper machines, turning on and off lights in factories or offices to give proper illumination without wasting of power, and determining the transparency of paper.

ELEVATOR EQUIPMENT

During the past year numerous improvements and refinements in elevator electrical equipment were made in keeping with the tendency toward higher speeds, automatic landing control, and quieter operation. The common trend toward combination units is also illustrated in elevator apparatus by building of motor-generator sets with exciter and control in one frame.

One of the completely new and interesting developments of the past year was the building of an elevator with two cars operating in one shaftway. Obviously the object of this arrangement is the saving of floor space in tall buildings where the space occupied by elevator shaftways is both valuable and large, inasmuch as the shaftway area must be subtracted from each floor. This elevator embodies all of the latest features in elevator design including automatic floor landing, door opening, and futuristically decorated cars. The cars use the floor bottom system of control and in addition a set of signals are displayed in each car indicating the relative position of both cars in the shaftway. The cars are prevented from approaching each other closer than two floors by an automatic block system of control which brings the car to a normal stop when this limiting distance is reached.

CONCLUSION

The Committee feels that there is a large field open for the electrical engineer in industry and that the Institute can be of material assistance to its members by bringing before them the important developments and trends in the various industries. In the preparation of this report we desire to acknowledge the assistance given by the various members of the committee and also by the Electric Machinery Manufacturing Co.

Instruments and Measurements

ANNUAL REPORT OF COMMITTEE ON INSTRUMENTS AND MEASUREMENTS*

THE Committee on Instruments and Measurements has been active during the past year on the following subjects:

1. Standard definitions for telemetering.
2. Standards for recording instruments.
3. Standards for indicating instruments.
4. Revision of Standards No. 14—Instrument Transformers.
5. Revision of Electrical Units.
6. Symposium on precision measurements.
7. Technique of temperature measurements.
8. Measurement of reactive power.
9. Method of measuring distortion factor.
10. Review of proposed papers.
11. Conclusion.

STANDARD DEFINITIONS FOR TELEMETERING

The subcommittee devoted to telemetering has been active for a number of years. Last year in this report there were published for comment standard definitions on this relatively new subject. It has been felt that, with the interest in the field of telemetering, it would be desirable to have some standard definitions so that the terms which are used would not be results from a hit and miss selection, as often occurs in newly developed fields. With comments received this year a set of standard definitions was approved by the membership of the Instruments and Measurements Committee, and is now ready for transmittal to the Standards Committee for adoption.

STANDARDS FOR RECORDING INSTRUMENTS

As a result of several years work, a subcommittee has completed a draft of proposed standards for recording instruments. These standards have been approved by the Instruments and Measurements Committee, and are now ready for submission to the Standards Committee.

The work of the subcommittee is under the chairmanship of Mr. Kinnard. A large amount of work has been involved in the development of these standards so as to cover this field of measuring instruments. The Committee has considered many new items which have shown that the Standards for Indicating Instruments should also be revised.

STANDARDS FOR INDICATING INSTRUMENTS

Since 1927, Instrument Standards No. 23 has been used by the industry. Since that time considerable progress has been made, and experience with the Standards has indicated that a revision would be desirable. A subcommittee was appointed at the beginning of this year to start the revision.

REVISION OF STANDARDS NO. 14—INSTRUMENT TRANSFORMERS

A subcommittee has been active during the past year revising Standards No. 14 covering instrument transformers. This standard was approved in 1925. It was the feeling of the members of the Instruments and Measurements Committee that progress in the art warranted revision at this time. The committee is under the chairmanship of Mr. Gibbs. Several tentative drafts have been prepared and revised so that these standards will soon be in form to be submitted to the Committee membership for approval.

REVISION OF ELECTRICAL UNITS

The report of the Committee on Instruments and Measurements for the Institute year ending July 31, 1929, contained a brief account of the participation of this Committee in the events which led up to the first meeting of the (international) Advisory Committee on Electricity at Paris in 1928. At that meeting resolutions of far-reaching importance were adopted, to the effect that the absolute system of electrical units, derived from the c. g. s. system, may be substituted with advantage for the present international system of units which is based upon arbitrary legalized material standards, namely, the mercury ohm and the silver voltameter.

The second meeting of the Advisory Committee on Electricity was held in Paris in June 1930. The American representative on the Committee, Dr. G. K. Burgess, Director of the Bureau of Standards, was prevented from attending, and sent Dr. H. B. Brooks as his substitute.

Representatives were sent by the national standardizing laboratories of England, Germany, Japan, and the Soviet Republics; by the Laboratoire Central d'Electricite of Paris, and the International Bureau of Weights and Measures at Sevres. Italy was represented by Professor L. Lombardi of the Royal School of Engineers at Rome. Other experts were present as invited guests. A large part of the sessions was taken up with the discussion of a new duty which the International Committee of Weights and Measures had recently laid upon the Advisory Committee on Electricity, namely, that of advising the International Committee on all questions relating to the methods of measurement and to the units and standards of light.

---

*COMMITTEE ON INSTRUMENTS AND MEASUREMENTS:

E. J. Rutan, Chairman,
H. S. Baker,
P. A. Borden,
H. B. Brooks,
O. J. Bushnell,
A. L. Cook,
E. D. Doyle,
Melville Eastham,
M. Eppley,
R. C. Fryer,
J. B. Gibbs,
W. N. Goodwin, Jr.,
I. F. Kinnard,
O. A. Knopp,
A. E. Knowlton,
H. C. Koenig,
W. B. Kouwenhoven,
F. A. Laws,
E. S. Lee,
Paul MacGahan,
R. T. Pierce,
W. J. Shackelton.

Concerning the primary standard of light, resolutions were adopted supporting the view that a black-body radiator should be adopted; requesting the national laboratories to examine the specifications for the Waidner-Burgess primary standard of light and to give their views regarding the practicability of its adoption; and urging the desirability of making additional determinations of the brightness of the black-body radiator, especially under the conditions prescribed by the Bureau of Standards' specifications, or at least under conditions comparable with them.

Concerning the unit of light and its maintenance, the Advisory Committee adopted a resolution to the effect that it is inexpedient to change the unit (*i. e.*, the international candle) which has been in use since 1909. Other resolutions adopted relate to the exchange and comparison of groups of lamps by the national standardizing laboratories, and to the adjustment of the values of the practical secondary standards, as may be necessary in the future as a result of reference to a primary standard.

Concerning the electrical units and standards, two resolutions were adopted, as follows:

1. With regard to the unit of resistance, the ohm, considering that methods of determining the absolute ohm are sufficiently advanced and that the agreement between the measurements of the coils (secondary standards) of the different laboratories remains within the limits of precision of the measurements, it is not necessary at present to undertake further comparisons of the resistance coils with mercury ohms.

2. As to the units of electromotive force, on the contrary, the international comparisons of standard cells show differences, exceeding the limits of possible precision, between the values of the electromotive force of the standards of different countries. The committee considers that it is absolutely necessary to make new determinations of the electromotive force of the international Weston cells in each national laboratory by means of the silver voltameter.

The conditions under which the silver voltameter should be used are specified sufficiently in the report of the international committee which met in Washington in 1910. The Advisory Committee recommends, however, that the national laboratories use the Smith or the Kohlrausch voltameter, avoiding organic material, which is detrimental to the electrolytic deposit.

The groups of Weston cells prepared in the several laboratories can be considered as sufficiently constant until the absolute unit of current shall be established.

It should be noted that these recommendations concerning standard cells and voltameters do not in any way modify the Advisory Committee's recommendation of 1928 looking to the ultimate legalization of the absolute ohm, volt, and ampere on a basis free from all arbitrary character. The recommendations merely recognize that the standard cell and the silver voltameter are useful tools, when properly used, and are essential to the maintenance and dissemination of the international electrical units under the existing limitations.

The Advisory Committee also made recommendations regarding the equipment of the International Bureau of Weights and Measures and plans for cooperation between that bureau and the national laboratories in work on electric and photometric standards. Since an international General Conference on Weights and Measures is to be held in 1933, the Advisory Committee decided that it should meet again before that time to study the comparisons of standards which shall have been made and to assign values in absolute units for the standards of resistance and of electromotive force.

SYMPOSIUM OF PRECISION MEASUREMENTS

In view of the recent activity of the International Advisory Committee on Electricity, it was felt desirable to have some outstanding papers written concerning the fundamental electrical units. The subject is being treated in a symposium which is being presented at the 1931 Summer Convention and which includes four papers. These are:

1. *International Standard of Electromotive Force and Its Low-Temperature Coefficient Form*, by Marion Eppley, the Eppley Laboratory, Inc.
2. *The Unit of Electrical Resistance; Past History and Impending Change*, by H. B. Brooks, National Bureau of Standards.
3. *Design of Potentiometers*, by I. Melville Stein, Leeds and Northrup Company.
4. *Electrical Units and Their Application*, by L. T. Robinson, General Electric Company.

TECHNIQUE OF TEMPERATURE MEASUREMENTS

In order to set up a standard code for temperature measurements, a subcommittee has been appointed. This committee has already analyzed all of the temperature requirements included in the various standards of the Institute, and is now summarizing these data preparatory to setting up the necessary measurement technique.

MEASUREMENT OF REACTIVE POWER

Considerable interest is being displayed in the matter of measurement of reactive power. A subcommittee has been considering this subject, and is cooperating with a committee appointed by the

Standards Committee under the chairmanship of Mr. A. E. Knowlton.

METHOD OF MEASURING DISTORTION FACTOR

In line with the recommendation of this Committee, made in last year's annual report, a subcommittee has been following the performance of Belfils Bridge which is being used by one of the manufacturing companies. The work has progressed to the point where a report has been prepared covering the performance of this apparatus. At the present time the report is in circulation among the members of the Instruments and Measurements Committee in order that their comments and recommendations may be obtained in regard to the suitability of this device for the measurement of distortion factor.

PAPERS

In addition to the four papers mentioned above in connection with the symposium of precision measurements, nine papers have been submitted to this Committee for review. Some of these have already been approved for publication and presentation and the remainder are in circulation and will be reported on shortly. These papers are listed below:

Measurements of Cable Insulation Characteristics

A High-Sensitive Power-Factor Bridge, by W. B. Kouwenhoven and A. Banos.

High-Voltage Bridge for Measurement of Cables with Grounded Sheaths, by C. F. Dawes and A. F. Daniel.

The Elimination of an Inherent Error in the Usual Form of Capacitance Bridge for Capacitance and Power-Factor Measurements by the Substitution Method, by R. P. Siskind.

Measurements of Magnetic Flux

Core Loss Measurements at High-Flux Densities, by B. M. Smith and C. Concordia.

This paper was presented at the Northeastern District Meeting, Rochester, N. Y., April 1931.

Miscellaneous Subjects

A Direct-Current Bushing Transformer, by A. S. Fitzgerald.

A New Overcurrent Relay with Straight Line Characteristics, by S. L. Goldsborough and R. M. Smith.

A Thermionic Type Automatic Synchronizer, by F. H. Gulliksen.

The Characteristics of the Oscillograph-Galvanometer, by V. S. Thomander.

The Amplifier-Oscillograph, by S. K. Waldorf.

CONCLUSION

Active interest has been shown by the members of the Committee on Instruments and Measurements through the year. The meetings held were well attended and subcommittee reports indicated considerable progress was being made in each of the assigned activities, and definite steps have been taken on several as indicated above. During the coming year it is expected to complete some of the other projects.

Applications to Iron and Steel Production

ANNUAL REPORT OF THE COMMITTEE ON APPLICATIONS TO IRON AND STEEL PRODUCTION*

THE functions of this committee have, in the past, been largely confined to (1) encouraging the presentation of papers before the Institute dealing with those phases of electrical engineering which are major factors in the utilization of electricity in the steel industry. (2) To preparing an annual report which briefly summarizes such phases of the application of electricity to the production of iron and steel as are considered new or of special interest to the membership.

During the past year, the committee's work has followed the previous precedent, in procuring papers. It also actively cooperated in arranging a joint session of the Institute with the Association of Iron and Steel Electrical Engineers at the meeting of the Middle Eastern District held in Pittsburgh on March 11th to 13th inclusive, 1931. The papers presented before this meeting which the members of this committee were active in procuring are as follows:

1. "Conversion and Distribution of General Purpose D-C. Power in Large Industrial Plants," by R. D. Abbiss, Carnegie Steel Co., and D. C. West, Westinghouse Elec. & Mfg. Co.
2. Symposium on Interconnection Between Utilities and Industries: Davison Coke and Iron Co. and Duquesne Light Co. Interconnection, by G. E. Dignan, Davison Coal and Iron Co. and R. L. Kirk, Duquesne Light Co.
3. "Interconnection of Power Supply Between Public Utilities and Large Industrial Users," by F. O. Schnure, Bethlehem Steel Co.
4. "Absorption of By-Product Power," by A. Hoeffle, Toledo Edison Co. and W. T. Woodmancy, Interlake Iron Corp.
5. "The Use of Electricity in Large Annealing Furnaces," by J. C. Woodson, Westinghouse Elec. & Mfg. Co.

The Committee wishes to report that this joint meeting of the Institute and the Association of Iron and Steel Electrical Engineers was a very successful part of the Middle Eastern District Meeting Program, and suggests that joint meetings with the Association of Iron and Steel Electrical Engineers be encouraged in the future.

ELECTRICAL DEVELOPMENTS IN THE IRON AND STEEL INDUSTRY DURING 1930

During the year 1930 there has been a general recession from the unusually high operating rates of the preceding year, and an accompanying reduction in expenditure for improvements and new plant facilities. However, an impressive amount of electrical equipment has been purchased and many interesting developments have taken place. Undoubtedly, the very successful electrification of rolling mills and their auxiliaries has been an important factor in the steel industry.

The iron and steel industry during 1930, purchased 163,490 total horsepower of main drive motors, rated 300 hp. or over, as compared to a total of approximately 350,000 hp. during 1929. The fact that the rate of increase in installed horsepower for main drives is greater than the rate of increase for ingot capacity, indicates the tendency to modernize old mills.

Direct Current Motors

Many important installations have been completed during 1930, with others rapidly nearing completion. From various viewpoints, a new 10,000-hp., 54-inch blooming mill in the Chicago District is memorable. It is the most powerful mill yet installed by a margin of 2,000 hp., an increase in power which will be useful in rolling thicker and heavier sections. This tends toward greater output of the whole plant, the blooming mill being the first of all the rolling operations.

Even more than for its size, this mill is unique in that the two main rolls, usually geared together, are driven individually, each by its own motor. This is a great improvement over the former method of a single motor coupled to a pinion stand. The ordinary construction of mill pinions and housings permits wear and misalinement from which develop accelerated wear, noise, vibration, and occasional breakage. Often the mill must continue in operation for several days after trouble has been developed before it can be conveniently shut down.

Each roll of the new 54-inch mill is driven by a double armature motor rated at 5,000 hp., 700 volts, direct current, at 40/80 r. p. m., both motors being under electrical control which keeps the speed of the two rolls precisely the same. The torque developed is 4,000,000 lb-ft., from standstill up to normal speed. The motors are of minimum diameter to avoid angularity of the mill spindles between motor and rolls, an incidental advantage being smaller inertia.

---

*COMMITTEE ON APPLICATIONS TO IRON AND STEEL PRODUCTION:

A. C. Cummins, Chairman,
F. B. Crosby,
M. M. Fowler,
S. L. Henderson,
A. M. MacCutcheon,
A. G. Pierce,
F. O. Schnure,
W. B. Shirk,
G. E. Stoltz,
Wilfred Sykes,
T. S. Towle,
H. A. Winne.

Immediately following the 54-inch blooming mill just referred to is the 52-inch beam mill. The roughing mill is driven by a 7,000-hp. reversing motor, and a 2,000-hp. reversing motor for the edging stand. Likewise the intermediate mill will be equipped with reversing motors rated at 6,000 hp. and 2,000 hp.

There is now under construction by this same company, a 44-inch universal slabbing mill, the driving motors of which will have a continuous capacity of 12,500 hp., and a maximum emergency capacity of 35,000 hp. The upper and lower horizontal rolls are to be individually driven by two 5,000-hp., 40/80-r. p. m. reversing motors, constituting a twin motor drive of 10,000 hp., 4,000,000 lb-ft. maximum torque capacity, duplicate of the 54-inch blooming mill now in operation. The vertical edging rolls are to be driven by a third reversing motor, rated 2,500 hp., 79/225 r. p. m., 500,000 lb-ft. maximum torque capacity. Power for the three reversing motors will be furnished by a 10,500-kw. flywheel motor-generator set consisting of a 180,000-lb. flywheel, a 6,500-hp., 25-cycle, 6,600-volt, 370-r. p. m. induction motor, and three 3,500-kw., 700-volt generators connected in parallel. This installation will be of unusual interest to steel mill engineers because of the large size of the mill and the electrical equipment, and also because of the method of drive, utilizing three reversing motors with control to provide adjustment of relative speeds, thus permitting variations in drafting and the use of rolls of unequal diameter.

To secure the necessary refinement for the accurate automatic control of the screwdown mechanisms on a 32-inch three-high universal plate mill and on roughing and intermediate 52-inch universal structural mills, seven variable-voltage screwdown equipments have been installed. The variable-voltage control permits much more accurate settings than could be obtained with rheostatic control, either automatic or manually operated, and thus speeds up the operation of the entire mill. A further advantage is the elimination of the large capacity reversing and accelerating contacts and starting resistor, with accompanying lowered maintenance.

In addition to the 54-inch and 44-inch mills referred to above, this company is also completing a 96-inch continuous plate mill, a 10-inch alloy bar mill, a large open-hearth department, and a 20,000-kw. addition to the existing steam turbine power station.

The 10-inch alloy bar mill will be driven by nine direct current motors, totaling 7,627 hp. Some of the motors have a speed range of approximately 5 to 1, which is obtained partly by motor field adjustments and partly by armature voltage control through the use of auxiliary bucking generators, one for each of two motors which have this large speed range. The use of these bucking generators permits operating the three main 1,750-kw., 600-volt generators in parallel at constant bus voltage. The motors will be equipped throughout with speed regulators of the vibrating type, designed to hold the speed regulation within very close limits.

An 8,000-hp., 40/100-r. p. m. reversing motor is now being built to drive a 44-inch blooming mill at Gary. This motor will be capable of developing a maximum torque of 2,900,000 lb-ft. The mechanical parts of this motor, including the armature spider, will be of fabricated steel construction throughout. Several reversing motors with fabricated and electrically welded armature spiders have been in service for some time, demonstrating beyond doubt the reliability of this type of construction. Power for the 8,000-hp. motor will be supplied by a 375-r. p. m. motor-generator set, consisting of two 3,500-kw. generators, one 6,000-hp., 6,600-volt, 25-cycle induction motor, and one 200,000-hp-sec. flywheel.

A southern steel company has placed in operation at Alabama City, a new 40-inch blooming mill which replaces an engine-driven 36-inch mill. The 40-inch mill is driven by a 7,000-hp., 700-volt, 50/120-r. p. m., single-armature reversing motor supplied with power from a 6,000-kw. flywheel motor-generator set. This company has also installed a new 32-inch three-high universal plate mill driven by a 4,000-hp., 80/160-r. p. m., d-c. motor, similar to a reversing mill motor, with variable-voltage power supplied by a 3,200-kw. flywheel motor-generator. The major part of the mill output is light gage sheets. The type of drive used permits the operator conveniently to select low speeds for the roughing passes, and high speeds for the finishing passes, with very rapid acceleration to the desired rolling speeds. An important feature of this mill is the automatic screwdown. When the operator moves the pass master switch to each successive position, the desired screwdown setting for each pass is obtained by automatic control.

A 20-inch continuous hot strip mill in the Detroit District was put into operation in 1930. This mill has ten stands, each driven by an individual d-c motor. The drive for this mill has one very interesting feature. When rolling from slabs of such length that the piece will reach from stand 4 to stand 5, the section of the bus to which the first four motors and one 5,000-kw. generator set are connected, is segregated from the bus to which the remainder of the motors and the other generators are connected. This is necessary because the minimum speeds of the first four motors when operating at normal rated voltage are such that the metal would be delivered from stand 4 at a very much higher speed than it enters stand 5. Consequently, when the piece is continuous between stands 4 and 5, the speeds of the first four stands must be lowered by reducing the voltage of the generators on the section of bus to which the first four motors are connected. A similar arrangement was incorporated in the control of the first two motors on the 60-inch strip mill in a plant at Steubenville, Ohio.

Motor drive has for the first time been successfully applied on a large scale to the operation of a 900-ton ingot pressing application that was formerly monopolized almost entirely by steam or hydraulic operation. This press is in the new plant of a wrought iron manufacturer near the Pittsburgh District and compresses wrought iron sponge balls, about five feet in diameter, into rectangular ingots, measuring about 6 ft. by 18 inches square, preparatory to rolling in the blooming mill. On the final squeeze, it is necessary to exert a pressure of at least 1,000 pounds per square inch. Maintenance of factory production at full speed, requires operating the rams up to 75 feet per minute. Still the motors and press must be protected from the enormous stress which would result if the ram was brought up suddenly against a solidly compressed ingot. The solution of these and other problems involved a coordination of generator, exciter, and motor characteristics with manual and automatic control facilities, so that, as the pressure increases, the ram speed is slowed up towards the end of its stroke and the current will never exceed the allowable limit.

The main 900-ton ram is driven, through four racks and eight pinions, by a double-armature, 1,200-hp., d-c. reversing motor, having a normal full-load speed of about 125 r. p. m., and a maximum light-load speed of 275 r. p. m. The motor was built with two armatures in order to reduce the $W R^2$ and to halve the current to be carried by each commutator. The auxiliary 200-ton end rams are driven by a 325-hp. single-armature motor, having a nominal full-load speed of 250 r. p. m. and a maximum light-load speed of 550 r. p. m. The motors are of sturdy mechanical construction, with cast steel armature spiders, special armature coil bracing, and thrust bearings at the coupling end. Rear enclosing end bells are provided so that the motors may be ventilated. This is necessary as the motors carry heavy loads at very low speeds, and are therefore incapable of self-ventilation.

Variable-voltage d-c. power for the two press motors is furnished by a four-unit synchronous motor-generator set, consisting of a 1,000-kw. generator for the large motor, a 300-kw. generator for the small motor, a 1,500-hp., 80 per cent power factor, 6,600-volt, three-phase, 60-cycle, synchronous driving motor, and a 50-kw., 250-volt exciter.

In addition to the electrical features enumerated, the mechanical design of the press incorporates a number of features intended to provide safe and reliable operation. The faces of the main ram head and stationary side stop are not smooth but have corrugations vertically and horizontally across them, so that on the first impact, only about 10 per cent of the total face of the ram strikes the ingot and the ram has to move in about 1½ inches before the entire face strikes.

The electrically driven press has been in operation several months, and its success has demonstrated the practicability of electrical drive for such machines.

A mill in the Youngstown District has purchased the electrical equipment for a 10-inch bar mill having 12 tandem stands. Ten d-c. motors totaling 7,350 hp. with variable-voltage control from two 2,000-kw. motor-generator sets will be used with this mill. The mill will have two unique features, one being the method of speed control and the other is the use of vertical motors to drive the vertical roll main stands.

A speed regulator of the carbon pile type is used with each motor and with a master frequency generator to maintain a desired speed relation between stands. The customary bevel gear drive to the rolls has been eliminated by the use of vertical motors. The vertical motor is mounted above the mill on an overhung support. This support also carries the rolls and pinion housing. The rolls can be moved sideways or up and down with respect to the bar being rolled so that the vertical rolls can be lined up with the grooves of the horizontal rolls.

Synchronous Motors

Among the more important synchronous motors which have been purchased during the year may be mentioned two 4,500-hp., 156.5-r. p. m., 6,600-volt, 60-cycle units which will drive two rolling mills in the plant of a Pennsylvania manufacturer. This company also purchased one 5,000-hp., 360-r. p. m., 6,600-volt synchronous motor to drive a 24-inch billet mill and one 4,000-hp., 360-r. p. m., 6,600-volt motor to drive a 28-inch billet mill at the same plant early this year. This company put into operation a 3,000-hp., 100-r. p. m., 11,000-volt, three-phase, 60-cycle synchronous motor, driving a three-high billet mill. This motor is of interest not only because it is one of the few main roll motors operating at over 6,600 volts, but also because it is started directly from the 11,000-volt circuit.

A West Virginia manufacturer has purchased two synchronous motors, one 2,000-hp., 800-r. p. m. and one 1,000-hp., 360-r. p. m., which will drive the hot tin mills. This is believed to be the first installation of synchronous motors on mills of this character, previous practise having been to use induction motors with flywheels. Synchronous motors were chosen because of the necessity of maintaining a good power factor, and also because of the gain in efficiency. Not only is the synchronous motor itself more efficient than the corresponding induction motor, but the friction and windage losses of the usual flywheel and the power losses in the secondary resistor or liquid slip regulator are eliminated. It is estimated that the power per ton of tin plate rolled will be at least 5 to 10 per cent less than if an induction motor flywheel drive had been used.

Switchgear

All the modern improvements in switchgear equipment are rapidly being adopted by the iron and steel industry. The metal clad type of switchgear with its live parts completely enclosed, excluding dust and dirt and at the same time protecting the operator from possible injury, is ideally suited to steel mill service.

Auxiliaries

Automatic screwdown equipment has been developed to the point where it will rapidly become more generally used. Two recent applications, one in a universal plate mill and the other in a structural mill have been mentioned in this article. The use of variable-voltage equipment for these screwdown drives has proved very desirable.

There is increasing industrial activity in the application of vacuum tubes and related devices. The crane operator on the soaking pit cranes for a 54-inch mill in the Chicago District will control the opening and closing of the soaking pit covers through the action of photoelectric cells. In another plant, a photoelectric cell acts as a "flag" switch to make the necessary set-up for registering the temperature of each billet as it approaches the rail mill. Undoubtedly, the field for such applications will rapidly increase.

The majority of the motor-driven heavy shears, such as bloom and slab shears, which are now in operation, are driven through clutches by induction motors equipped with flywheels. The mechanical clutches are a source of more or less trouble, and to eliminate these and also the losses in the continuously running motor and flywheel, several shears have recently been installed with d-c. motor drives, arranged to start and stop with each cut.

Two of these are in a new plant near Detroit. The larger of the two is an 800-ton slab shear, designed to cut a slab 8 inches thick by 25 inches wide. Another midwestern steel plant has recently placed in operation eight shears, cutting cold stock up to a maximum of ¼ inch thick by 42 inches wide. Some idea of the high rate of acceleration and retardation may be obtained from the fact that the shear makes a complete cycle in less than one second, and during this time the motor starts from rest, attains a speed of over 450 r. p. m., cuts the plate and stops.

A Pittsburgh tube mill has installed two scrap shears for crushing and shearing pipe up to 24 inches. They are of the new type with the shear motors starting and stopping for each cycle.

What is believed to be the first application of synchronous motors to flying shear drive is in connection with a 20-inch hot strip mill in the Detroit District. The shear is of the rotary flying type, and, to insure that the metal shall be cut into equal lengths, it is necessary that the speed of shear be synchronized with the delivery speed of the metal from the mill. To accomplish this, an a-c. generator is provided on each stand, from which the metal may be delivered. The shear is driven by a synchronous motor, the power for which may be obtained from any of the a-c. generators.

Three ore unloaders recently placed in operation at one of the Lake Erie Docks are interesting on account of their large size. The combined capacity of the three unloaders is 3,600 tons per hour, and the actual time for unloading a 10,000-ton boat is four or five hours. The bucket capacity for each unloader is 17 tons. Each unloader uses eight motors totaling 1,060 hp. The beam hoist motor is a 350-hp., 500-r. p. m., shunt-wound mill motor and the trolley travel motor is a 170-hp. motor, these two motors having variable voltage control. The bucket closing and opening motor is a two-speed wound-rotor mill type motor, and all other motors are a-c. motors. The motor-generator set for the variable-voltage control is mounted inside the beam and serves to help balance the stiff-leg weight.

As electrical improvements in the iron and steel industry are reviewed each year, the opportunities that exist for improvements in steel mill drives and auxiliary equipment become increasingly evident. These improvements will result from a close cooperation between the steel plant engineer, the mill builders, and the engineers of the electrical manufacturer.

Production and Application of Light

ANNUAL REPORT OF THE COMMITTEE ON PRODUCTION AND APPLICATION OF LIGHT*

PRODUCTION OF LIGHT

Statistics on Incandescent Lamp Sales

THE sale of incandescent lamps held up remarkably well during the past year, large lamps showing a decrease of about 1 per cent as compared with 1929. The Central Station revenue derived from the two classes of service in which light is a large factor (domestic and commercial, small power and light) showed an increase of about 7.5 per cent as compared with the previous year, offsetting the reduction from other uses of electricity, and leaving a net increase of about 3 per cent.

The average lumens, watts, and efficiency of the large lamps sold last year all increased as compared with the year before. The average lumens went from 797 to 814; the average watts from 60.7 to 61.2 and the average lumens per watt 13.1 to 13.3.

Of the sixteen standard wattages from 10 to 1,000 inclusive, used in multiple service, three sizes 60, 100, and 200 watts, represent nearly half (46.6 per cent) of the total wattage demand.

The percentage of 110-volt and 115-volt lamps sold decreased slightly, while that of 120-volt gained as compared with the previous year. The percentage distribution for last year for 110-, 115-, and 120-volt lamps was 5.2 per cent, 48.9 per cent, and 41.3 per cent respectively. Lamps for 200-250-volt service decreased from 3.3 per cent to 2.6 per cent of the total quantity sold for multiple service.

The demand for street series lamps is concentrating on the 6.6 ampere rating. This now represents 71.2 per cent of the total; the next largest demand being 14.6 per cent which is for the 15- and 20-ampere compensator type lamps.

New Sources of Ultraviolet Radiation

A new type of lamp (called a glow lamp) has been developed which produces ultraviolet light by virtue of a glow discharge through mercury vapor between two hot cathodes of the oxide coated type. The two heater filaments for the cathodes are connected in series and their resistance produces a sufficient difference in potential to cause a discharge between the two cathodes, once they have become heated. The lamp is rated at 2 amperes and 18 volts. This lamp, designed for operation on alternating current requires a starting potential of some 35 volts, after which 18 volts is sufficient to maintain the discharge. One, two or three lamps may be operated on the ordinary 115-volt lighting circuit in connection with a suitable current-limiting resistance, reactance, or transformer. The glass bulb has been selected for its transmission characteristics so that the lamp will produce practically no radiation below 2,800 Angstrom units. In addition to producing the desirable radiations of ultraviolet light, it also produces blue and green light in the visible spectrum which may possibly be used to advantage in the future to supplement the light of Mazda lamps, to secure a nearer approach to a light subjectively white in color as well as to obtain the healthful ultraviolet radiation.

In last years report a new tungsten-mercury arc lamp was referred to. This lamp consumed about 315 watts. A lamp of the same general characteristics, but of about forty per cent of this wattage has recently been announced. The bulb is smaller, and is fitted with a metal cap which raises the operating temperature and pressure of mercury vapor in the bulb, and increases the efficiency of production of ultraviolet radiation. The ultraviolet output of the new lamp is approximately one-half of that of the older one. The transformer to be used with the new lamp weighs about 7½ pounds and is small enough so that it can easily be embodied in the design of fixtures, to permit a wider use of this type of lamp, especially a source for dual lighting service.

Still another type of lamp employing a tungsten filament, operated at a high temperature has been found to produce ultraviolet radiation in the biologically active range in sufficient quantity to be of value at least to poultry and animals where exposure times are not too short. Lamps for such service must, of course, be made with special bulbs which will transmit this radiation, and two sizes, 60 and 500 watts for operation on standard lighting circuits have been made available.

A powerful, long-burning type of carbon arc has been developed for the production of ultraviolet radiation which was described in an illumination item in the December issue of the A. I. E. E. Journal, page 1031.

Gaseous Conductor Sources of Light

An arc, in an atmosphere of krypton and sodium, has been described by Dr. M. Pirani.* This operates in a

G. H. Stickney.

tube about one inch in diameter and 35 inches long which has to be maintained at a temperature of 350 deg. cent. (somewhat above the melting point of lead). A very high efficiency, about 70 per cent of the theoretical maximum, is obtained based on the input to the arc alone. With the supplementary heating required, the over-all efficiency would, of course, be reduced. Previous to this time sodium arcs with efficiencies of from 50 to 70 lumens per watt have been described. The light from such lamps, however, is nearly monochromatic and would, alone, be of limited utility for ordinary lighting service.

Dr. Pirani has also obtained great increases in brilliancy in mercury and in neon discharge tubes.†

The combination of hot cathode neon and mercury vapor lamps to produce light apparently white in color, at a high efficiency, (mentioned in our report for 1928) is again attracting interest, as is also the combination of the mercury arc with incandescent lamps.

Small Gaseous Conductor Lamps

These small negative glow lamps used for night lamps, indicative and current detectors, are now designed to operate on line voltages from 90 to 130, and to consume from 0.01 to 2 watts,. The former is merely an indicator, the latter gives a maximum normal candlepower of 0.2.

Photoflash Lamp

A lamp has been designed to produce a high intensity flash for use in photographic work, consisting essentially of crumpled aluminum foil in an atmosphere of oxygen, which is ignited by a small filament that can be operated on any voltage from 2 to 130. It is made in a bulb of the size and shape of the 100 watt lamp used for general lighting service.

The flash lasts approximately 0.02 second, the radiation is about such as would be obtained from a black body at a temperature of 4,000 deg. K. The flash is equivalent in candlepower to about 250 ordinary 500-watt lamps. It is noiseless and fumeless, the products of combustion being retained within the bulb. The lamp is finding wide use in the photographic field.

40-Watt, Gas-filled Lamp

The 40-watt lamp for ordinary lighting service is being changed from a vacuum to a gas-filled type, and, at the same time put in a slightly smaller bulb. The initial efficiency of the new lamp is slightly higher, and the light output is maintained better throughout life.

50-Watt Lamp

The 50-watt incandescent lamp, for general lighting service, has been removed from the regular schedules of the manufacturers of Mazda lamps. Its demand can apparently be shifted largely to the 60-watt size which is gaining steadily in popularity. The three sizes, 40, 50, and 60 represented unnecessarily close steps.

New Incandescent Lamps

Three new lamps for 110-, 115-, and 120-volt lighting service have recently appeared on the market. These are, a 5-watt lamp in a bulb ¾ inch in diameter, a 100-watt in a tubular bulb 34 inches long, and a 150-watt in a tubular bulb about 12 inches long.

APPLICATION OF LIGHT

Ultraviolet

The utility of ultraviolet radiation for purposes, other than merely the prevention of rickets, has been attracting wide attention and has been the subject of much experimental work. Its most promising physiological benefits seem to lie in the direction of prevention of colds and relief of anaemia. In the industrial field powerful carbon arcs are used for making accelerated tests (which must however be carefully evaluated) and for the treatment of food, tobacco, and other products. Small incandescent sources can be used in poultry houses with good effect.

The use of screens with arc sources to absorb the ultraviolet radiation shorter than that which it is desired to use, has grown during the past year, particularly in outfits intended for use in the home. A time limit switch is also incorporated with some outfits to reduce the probability of over-exposure. The development of very powerful arc sources with long-burning carbons, has extended the possible use of ultraviolet radiation in both industrial service, and in treating large groups in hospitals and sanatoriums.

Trends in Lighting Practise—1930

The interest of architects and decorators in the use of artificial light as a component part of their decorative scheme, is becoming more and more widespread. At first the new ideas were accepted in only the larger cities, now in most of the smaller cities and larger towns excellent examples of the new practise can be found.

Instead of trying to imitate flame sources, candles and oil lamps in fixtures intended for rooms of classical treatment, the skillful designer produces a luminaire which serves the modern light sources in an effective manner and then incorporates in the detail of decoration elements which are inherent to the decorative period under consideration.

The more commercial or stock fixtures which have appeared on the market during the last few months exhibit a tendency to new forms, characterized in general by simplicity of line and pleasing proportions.

If satisfactory illumination is to be obtained from side wall outlets, these must be fitted with some sort of device quite different from the ordinary candlestick bracket. Manufacturers are beginning to realize the possibility of so-called semi-indirect, side wall pockets or urns and a number of interesting varieties have been placed on the market during the period under consideration.

Only a few years ago it was the practise to finish the building and then choose the lighting fixtures. As a result they often tended to appear as an incongruous after-thought, and not a component part of the structure. We are now seeing many instances of what has been termed "built-in" lighting, but these arrangements cannot be carried out unless suitable provision is made in the initial plans for the placement of lighting equipment.

---

*Zeitschrift fur Technesche Physik—Nov. 1930.

†*E. T. Z.*,—June, 1930.

There is a growing appreciation of the value of light to look at (as well as to see by) and in the more modern buildings we see interesting installations of luminous panels, niches, and touches of color which give no useful illumination but are pleasing to the eye.

Naval architects and ship owners realize that their vessels must be made more interesting from a decorative standpoint if they are to attract patronage under conditions of severe competition, and decorative lighting is receiving more attention than ever before in marine service.

There seems to be a trend in commercial lighting practise toward the greater use of indirect lighting equipment, both semi-indirect and totally indirect. Such forms of lighting which are desirable for general use in commercial interiors have been rather slow in being adopted probably because they require better maintenance than the enclosing globes.

Technical progress has been made in practically every field of lighting. In some of the newer ones, such as lighting for outdoor sports and for aviation, there has, in addition, been a very rapid growth. There have been no revolutionary changes, however, in equipment and methods generally employed.

Windowless Buildings

Perhaps the most outstanding development in connection with the use of daylight or artificial light for buildings that has taken place to date was started during the past year. The new factory of the Simonds Saw & Steel Company, Fitchburg, Mass., which is now nearing completion is built entirely without window openings. This pioneering project is receiving much publicity and the results will unquestionably be watched with interest and have a distinct bearing on the future building construction. In this building lighting units consisting of a combination of mercury vapor tubes and tungsten filament lamps will be used to secure a subjectively white color of light. Some of the tubes will be of ultraviolet transmitting glass to provide the desired amount of such radiation. Another notable example of this nature is the Parker Bridget Department Store in Washington, D. C. This store depends entirely on artificial illumination for its operation. It is felt that by eliminating windows lighting conditions are constant at all times. It is much easier to accurately control temperature and ventilation. Then, too, from a merchandising standpoint the larger percentage of wall area is available for display space.

With the record for continuity of service which has been attained by the central stations. and the development of effective means of lighting, ventilation and air conditioning, windows are no longer essential. There are so many advantages to be gained by their elimination in certain classes of use, that it appears as though this subject will receive increasing attention in the future.

Proper Operating Voltage

The N. E. L. A. Lamp Committee gives in its report this year, the results of further surveys of socket voltages, which show some improvement in the average value as compared with the sample cities studied the year before. The spread in voltage, however, shows no improvement. The results given in these surveys apply particularly to residential service. In large office buildings and industrial plants the average socket voltage is probably relatively lower than in residential service because of the greater voltage drop in interior wiring.

The N. E. L. A. Lamp Committee Report for 1928 contained a summary of data on operating voltages as reported in use for some 18,000 communities. This summary showed that 5.4 per cent of the population considered was in communities served at more than one standard voltage. Five years earlier the percentage had been 13.2. This trend toward the use of one standard operating voltage in each community aided in putting lamps of correct voltage in service, because, it is obviously difficult, if not impossible, to avoid mixing voltages in service where two or more standards are in use. The maintenance of but one standard service voltage throughout a community makes it much easier to be sure that lamps of only the correct voltage are used, and this is important from the standpoint of lighting service in general.

Minimum Wiring Specifications

In addition to the minimum specifications for the adequate wiring of lighting circuits in commercial and public structures, mentioned in last years report, specifications covering industrial and residential service will soon be made available as a result of further work by N. E. L. A. Committees. All of these specifications are in such simple form that they can be used with the greatest ease. They provide minimum standards to which all new buildings should conform in the interests of good lighting service. We again recommend that every electrical engineer who is brought into contact with the design or operation of lighting installations should be familiar with these specifications.

Stroboscopic Developments

A new type of stroboscope has been developed in which the discharge characteristics of a three-element grid glow tube are utilized in conjunction with a condenser to produce the brilliant flashes of light of exceedingly short duration and high frequency needed in such work. Another method, described in German technical literature produces flashes of the desired character by the combination of motion of three disks carrying different numbers of radial slits. A more complete description of these devices has been submitted for publication as an Illumination Item.

Group Replacements

The replacement of incandescent lamps in street lighting service in complete groups rather than individually as failures occur, offers a possible means of securing a higher general level of illumination and reducing the number of outages at no increase in operating cost. It is being used, or tried out, in a number of localities. If the burning hours of all the lamps in a large group are identical, and if the cost of replacing lamps individually as they burn out is relatively high, it may be advantageous to replace the entire lot as soon as the burnouts begin to occur with some frequency, which will ordinarily be at the time the lamps have attained about 70 per cent of their average life. If this general replacement is made to coincide with one of the periodic cleanings of the lighting equipment the replacement cost per lamp is relatively small. This same practise might well be applied in other classes of service, where the cost of making individual replacements is relatively high, and where all the lamps in a large group burn the same length of time.

Fixed Focus Automobile Headlights

It has long been recognized that one of the greatest factors contributing toward glare from automobile headlights has been the fact that the lamp filaments were not properly focused in the reflectors. Although the system of approval of headlight equipment by the motor vehicle authorities of the various states after laboratory test has become quite general and all cars are equipped with head lamps capable of producing adequate road light with minimum glare, it has been impossible to keep these equipments in proper adjustment in the hands of the public. The motorists may learn to aim the headlight beams properly, but the more intricate operation of focusing the filament in the reflector has proved a stumbling block.

Because improvements in lamp manufacture now permit more accurate location of the filaments with respect to the lamp base, and because headlight reflector and lens combinations have been designed that are less sensitive to focal adjustment, it has become possible for the motor vehicle authorities to approve the use of so-called "fixed focus" headlamps from which the focusing mechanisms are entirely eliminated. The sockets in these headlamps are rigidly fastened in the reflectors and the filaments in the lamps of any reputable manufacturer in this country are accurately designed to fit them so that an acceptable beam can be secured by simply inserting the lamp in the socket.

Headlamps of this type are already being used by several of the motor car manufacturers and improvements in the general headlight situation are to be expected as their use becomes more widespread and cars with the old types of equipment are gradually replaced on the highways.

GENERAL

Present Status of Candlepower Standards

While the needs of practical photometry have been met reasonably well for many years by the expedient of establishing units of candlepower maintained by means of electric incandescent lamps, this procedure does not give a permanent solution for the problem of photometric standards. There remain unsettled three major difficulties: 1. Several countries, particularly Germany and Austria, still use the Hefner unit, which is 0.9 of the unit recognized by the International Commission on Illumination; 2. no reproducible primary standard has been accepted as representing the international unit which was established for carbon-filament lamps; 3. no specific method has been agreed upon for passing from the carbon-filament lamps to those giving light of other colors.

These difficulties have resulted in discrepancies between measurements made in different countries. The differences are large enough to be very serious in such precise measurements as are made in rating and testing incandescent lamps. Consequently efforts have been made for several years to find a basis for a comprehensive international agreement on this subject. These efforts have been furthered by discussion at several sessions of the International Commission on Illumination. In order to give a more definite legal status to the negotiations the International Committee on Weights and Measures decided in 1929 to take up the problem of photometric units and standards, collaborating with the Commission on Illumination. Both of these organizations meet in 1931, and it is hoped that some definite progress can be made toward the solution of the problem.

As a basis for action, an international Advisory Committee on Electricity, meeting in June, 1930, has prepared recommendations which may be summarized briefly as follows:

1. As a *primary standard of light* a black-body radiator is definitely recommended; other laboratories are asked to consider the specific form of standard which has been developed by the Bureau of Standards, and to make determinations on that form or on others which will be comparable with it.
2. As a *unit* for general use the present international candle is to be retained.
3. Present discrepancies between basic units at carbon-filament color as maintained in the different national laboratories are to be reconciled by comparisons now in progress, and thereafter periodic comparisons and necessary adjustments are to be made under the auspices of the International Committee on Weights and Measures.
4. Through comparisons of colored filters now under way between the national laboratories it is hoped that agreement can be reached on a standard method for measuring lights of various colors. This method can then be used in setting up practical standards for lamps of various types, all based upon the primary standard and all consistent with each other.

Architects and Lighting

During the past year the Illuminating Engineering Society has given great attention to securing better cooperation between the architects and illuminating engineers. As one approach to this problem, three very well attended schools on architectural problems have been held, one at Columbia University, one at Chicago, and one at the Massachusetts Institute of Technology. Such schools for illuminating engineers serve to acquaint them with architects' viewpoints and nomenclature, thus helping to bridge the gap between the two professions. On the part of practising architects greater attention than ever before has been given to coordinating lighting with building design.

Important steps have been taken in fostering better lighting in the homes and schools of the United States. In this manner the best principles of lighting have been made available to school boards and home owners. This work is spreading rapidly.

A code of principles of Street Lighting has been prepared by the Street Lighting Committee of the Illuminating Engineering Society, which is likely to take a very important part in guiding the practise in this field. For the first time experts and engineers representing diverse interests and viewpoints have been able to agree upon a statement of some of the fundamental factors involved.

The Lamp Committee of the National Electric Light Association presents each year to that association a report in which the statistics relating to incandescent lamp production are analyzed in detail, and in which important developments in the production and application of light are reviewed. Those who wish more detailed statistics, as well as those who are concerned with the commercial and engineering problems of lighting, will find valuable the reports of various committees of the National Electric Light Association and the Illuminating Engineering Society.

The Committee wishes to record its appreciation for the assistance rendered in the preparation of this report by Dr. E. C. Crittenden (who contributed the section on the Present Status of Candlepower Standards), Mr. A. L. Powell, and Mr. A. B. Oday.

Applications to Mining Work

ANNUAL REPORT OF COMMITTEE ON APPLICATIONS TO MINING WORK*

THERE has been a minimum of new installations made this year owing to the general depression.

Hoists. Probably fewer hoists have been installed than in many past years. It is interesting to note that two manufacturing companies alone report that combined they have sold to date nearly 800 induction motor hoists from 200 to 1,800 hp. in size, and over 100 variable control d-c. hoists from 200 to 5,000 hp., the latter two motors in series.

Cleaning Plants. There is a continued trend toward larger and more complete preparation plants especially at mines using mechanical loading instead of hand loading. One plant, Hazle Brook Coal Co., has installed two 200-hp. Westinghouse synchronous motor drives.

Shovels. Electrification of 4- to 10-yard shovels has continued in the metal mines.

Mining Machines. The manufacturers of this specialized electrically driven equipment have been very active in producing new types of mobile high-powered machines. These machines now undercut from 600 to 1,200 tons per day in contrast with older types which did well to undercut 200 tons per day. See Fig. 1.

Loading Machines. Rapid increase of the amount of coal mechanically loaded indicates that these labor saving devices are permanently established in the industry. Various makes have sustained records of 350 to 500 tons loaded per 8 hours. Probably there are 500 such machines now in operation.

Welding. In addition to miscellaneous repair work by electric arc welding several companies have installed full automatic welding heads to be used for filling up the worn tread of locomotive tires and wheels. This has been quite successful and undoubtedly will be very generally used.

FIG. 1—JEFFREY 29L TRACK-MOUNTED CUTTER

Safety Work. The Bureau of Mines has continued to test and approve many new devices for mining work.

NOTE: Many references to miscellaneous improvements and applications are given in the *Coal Age*, Vol. 36, No. 2, Feb. 1931, p. 76.

Applications to Marine Work

ANNUAL REPORT OF COMMITTEE ON MARINE WORK*

THE major items of activity of the committee for the current term have been:

a. Reprinting Standards No. 45—Recommended Practise for Electrical Installations on Shipboard.

b. Promoting licensing of the electrical operating personnel on shipboard.

c. Keeping in touch with electric propulsion of ships and the electrification of auxiliaries on shipboard.

STANDARDS NO. 45

During the last term of this committee these standards were completely revised to incorporate developments and expansion in the marine practise since the previous issue of June 1927. They were carefully edited and reprinted in October 1930 and are being rapidly sold to all departments of the marine industry interested in electrical work. These standards are recognized and accepted by the various marine classification and insurance societies, naval architects, marine engineers, shipbuilders, and ship owners and are being incorporated in many of the specifications regulating the construction and repair of ships. The increasing use of them testifies to the need of such rules in order to standardize the electrical installations on shipboard and to stimulate the use and proper care of electrical machinery in the marine field.

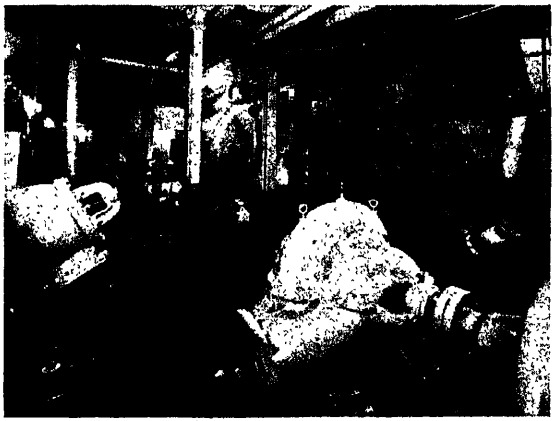

FIG. 1—VIEW IN LOWER ENGINE ROOM, *S. S. Morro Castle*

Propulsion motor in background

They are referred to in the various rules of classification societies not as a requirement but as representing good practise. This regard for these rules is justly merited due to the many years of hard work by experienced representatives of the diversified interests composing the marine field.

The fire alarm rules in the present Steamboat Inspection Service are consistent with the Standards No. 45 and were referred to this committee during their preparation.

OPERATING PERSONNEL

Our efforts were continued with the Steamboat Inspection Service to obtain classification and rating for electrical operating engineers on shipboard.

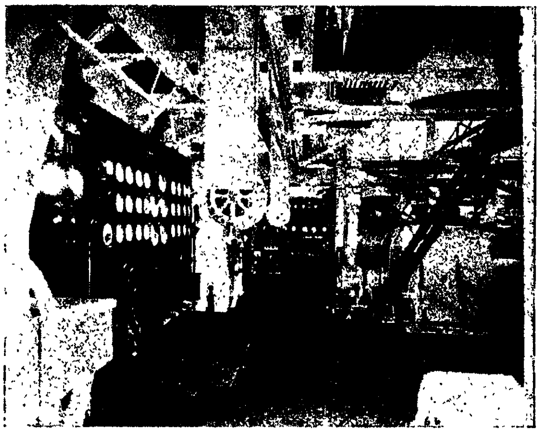

FIG. 2—VIEW IN UPPER ENGINE ROOM, *S. S. Morro Castle*

Propulsion control at left and generators at right

A review of the work of the subcommittee in charge of this item carries one back to the year 1922 when overtures were made to the Steamboat Inspection Service to require the operating personnel on vessels with electric plants to qualify and obtain electrical licenses.

The committee's efforts to date have been rewarded by a slight raising in the standard of the electrical questions in the examination for license for steam and combustion engineers.

W. H. Reed,
E. P. Slack,
H. M. Southgate,
W. E. Thau,
J. Van der Dussen,
A. E. Waller,
O. A. Wilde,
J. L. Wilson,
R. L. Witham,
W. N. Zippler.

The Board of Supervising Inspectors has been very courteous and granted a number of hearings. The necessity for the requested action, is recognized by a few of the supervising inspectors and it is hoped that there will soon be a sufficient number to put the movement into effect.

The cause for this movement was the improper maintenance of electrical equipment on shipboard and is today perhaps more prominent than when the movement was started owing to the increase in the use of electrical apparatus and auxiliaries, with the exception of vessels equipped with electric propulsion and all of these are not immune.

On electrically propelled vessels the standard of the electrical force is somewhat higher than on other vessels. Consequently, the electrical apparatus and auxiliaries receive the benefit of more expert attention.

The committee has been in touch with the President of the American Steamship Owners Association soliciting its good offices. Our committee was cordially received and has been requested to submit its proposal relative to the absence of knowledge and training on the part of the operating personnel. This proposal is almost complete and it is hoped it will be submitted at an early date.

The subcommittee is keeping in close touch with this situation and is optimistic in feeling that favorable action will be taken by the Steamboat Inspection Service before long and their regulations modified accordingly.

ELECTRIC PROPULSION AND ELECTRIC AUXILIARIES

The year 1930 takes its place in marine history of the United States with a record of activity, progress, and accomplishment in shipbuilding and marine engineering, which has not been approached since the busy days of the World War. This is, of course, due largely to the stimulation resulting from the Jones-White Merchant Marine act of 1928, which has made available to American ship operators, large mail contracts and loans at low interest rates for construction of new vessels. Thus, our merchant marine is to receive a much needed strengthening by the addition of a fleet of fine ships now under construction or in process of design.

In the design of these last words in naval architecture, electricity has taken an outstanding place. Some will be propelled by means of electricity. All will have electrically driven auxiliaries which are so necessary to the operation of the ship. Electrical appliances will add to the comfort and convenience of the passengers.

In order to illustrate the progress of electric propulsion especially during the past year the following data covering vessels completed or contracted for to January 1, 1931, are listed below.

	Hp.	No. vessels
Total turbine electric in U. S. A.	867,600	62
Total turbine electric outside U. S. A.	127,900	9
Total	995,500	71
Commissioned or under construction during 1930 in U. S. A.	196,900	20
Total diesel electric in U. S. A.	88,280	121
Total diesel electric outside U. S. A.	16,700	8
Total	104,980	129
Commissioned or under construction during 1930 in U. S. A.	15,195	25

It may be interesting to know the individual vessels and their horsepowers involved in the above figures.

Name		Horsepower
Turbine Electric Drive—Ships Commissioned During 1930 in U. S. A.		
Santa Clara		12,600
Morro Castle		16,000
Oriente		16,000
City of Flint (Great Lakes Car Ferry)		7,200
Corsair		6,000
4—Coast Guard Cutters		12,880
2—River towboats		4,000
Total		74,680
Turbine Electric Drive Equipments—Under Construction During 1930		
President Hoover		26,500
President Coolidge		26,500
United Fruit Co.—6 ships 11,000 hp. each		66,000
One Coast Guard Cutter		3,220
Total		122,220
Diesel Electric Drive—Installed During 1930		
Frying Pan	Lightship	350
Fenwick Island	Lightship	350
Nantucket	Lightship	350
Tidewater	Tanker	1,000
Ward Island	Ferry	400
Tenkenas	Ferry	400
Veedol No. 2	Tanker	1,000

L. T. C. No. 2	Tanker	500
L. T. C. No. 3	Tanker	500
Liston	Survey Boat	350
Scott	Towboat	150
Ft. Armstrong	Towboat	150
Cleveland	Tug	800
Rochester	Tug	800
Scranton	Tug	800
Oleon	Tug	800
Venus	Tug	515
Luna	Tug	515
Prescottont	Tug	800
One tug *Vandyke No. 4.*		425
Total		11,455
Diesel Electric Drive—Under Construction		
One yacht		660
One tanker		200
One fireboat		2,130
One ferryboat		750
Total		3,740

Prior to the commissioning of the *S. S. California* in 1928 the total turbine-electric horsepower installed on merchant ships was but 38,800. Out of a total of 356,200 horsepower completed and in course of construction as of the end of 1930, 317,400 horsepower, or

89 per cent, was undertaken during the past three years.

Slightly apart from the marine field, but with equal interest to it, was the installation of a central station in the *Jacona,* which is to be used as a mobile and subsidiary power plant along the shores of the New England Coast. Two turbine generators were installed, each rated 10,000 kilowatts for delivering power ashore at 6,600 volts or 11,400 volts three-phase 60 cycles.

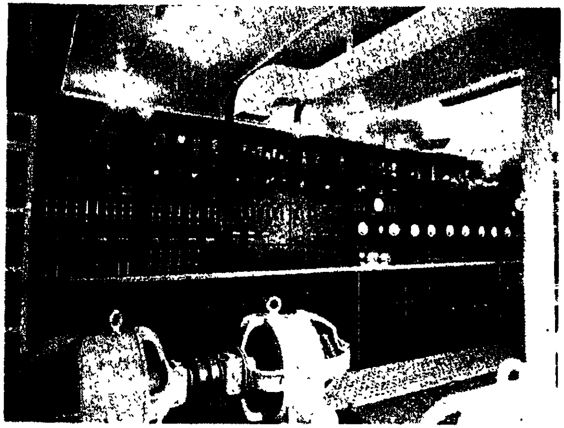

Fig. 3—Auxiliary D-C. Switchboard, *S. S. Morro Castle*

During 1930, a 96-in. (wheel diameter) gyroscopic stabilizer complete with electrical equipment, was constructed. This unit will be installed in a large yacht. A second unit with 11-ft. diameter wheel, complete with electrical driving motors, control and turbine generator set for power supply, is nearing completion for installation on one of the largest yachts ever built. The casing of this stabilizer will be of welded construction.

During the year 1930 great strides were made in shipboard installations of modern watertight door control systems. This system provides that in the event of collision electric operation of the watertight bulkhead doors is instantly available. The system provides remote control of the watertight doors from the wheel house as well as at the door itself.

It is the intention of this committee to keep Standards No. 45 up to date and assist in any practicable way the various classification societies and other bodies or interests in the marine field in the application of electricity to marine use.

We further are ready to cooperate with the American Marine Standards Committee in establishing electrical marine standards such as watertight receptacles, etc.

Power Generation

ANNUAL REPORT OF COMMITTEE ON POWER GENERATION*

TWO meetings of the entire committee were held during the year, one at the Philadelphia District Meeting on October 14, 1930, and the second at the Winter Convention in New York on January 28, 1931. In addition to the regular survey of immediate developments and problems in the scope of the committee, a continuing organization or method was adopted through which news items on the subject of power generation will be reported for publication in ELECTRICAL ENGINEERING. Each member of the committee was asked to appoint some one of his business associates as a permanent news correspondent to represent his particular affiliation irrespective of membership in the future on the Power Generation Committee.

The subject of interconnection continued to occupy the major attention of the committee, and especially of the Joint Interconnection Subcommittee on which Messrs. F. C. Hanker, F. H. Hollister, and A. E. Silver represented the Power Generation Committee. The formation of this subcommittee composed of members from the Power Generation, Power Transmission and Distribution and Protective Devices Committees, was predicted in last year's report, and the subcommittee has functioned throughout the year under Mr. Hanker's chairmanship not only to the fullest extent, but has also promoted a close working arrangement among the three main committees in dealing with a subject that has many common elements.

The Joint Interconnection Subcommittee has directed the preparation of a second report on "Grounding," which was presented at the Pittsburgh meeting in March 1931 under the title *Present Day Practise in Grounding of Transmission Systems*, and while of technical import to this committee, is also of interest because the original report on *Grounding* was prepared in 1923 by Mr. E. C. Stone now of the Power Generation Committee.

The Interconnection subcommittee has also sponsored a session in this summer's convention, consisting of four papers that treat the subject of interconnection primarily from the viewpoint of geographical, as contrasted to urban territory, interconnection. The introductory paper, prepared by Mr. Alex. E. Bauhan, is a comprehensive summary of the various services rendered by interconnection, and an exposition of the methods of evaluating the economies to be secured. Two papers that illustrate the plans and operating procedures adopted in different regions, are as follows:

Interconnection in New England, by E. W. Dillard and W. R. Bell; *The Pennsylvania-Ohio-West Virginia Interconnection*, by Howard S. Fitch.

The fourth paper, by G. M. Keenan, is on *Load and Frequency Control on Interconnected Systems* and summarizes the methods in use and the experience on the subject that has accumulated in the past two to three years on practically all the major system interconnections in this country.

The committee reviewed during the year and recommended as of great interest on the subject of interconnection other papers as follows:

Governor Performance During System Disturbances, by R. C. Buell, R. J. Caughey, E. M. Hunter, and V. M. Marquis.

Reestablishing Excitation of a Loaded Alternator in Parallel with Others, by D. D. Higgins and E. Wild.

Other papers describing the design of modern power plants that have been reviewed by the committee include the following:

The Ohio Falls Hydroelectric Station at Louisville, Kentucky, by R. M. Stanley and E. D. Wood.

Modern Steam Stations of Duke Power Company, by Marshall E. Lake.

Steam Power Development of the Pacific Gas and Electric Company, by Richard C. Powell.

Two papers with an introductory summary have been initiated and are now in preparation on the subject of steam and electric drives. These papers are being written in collaboration for the purpose of uniform presentation, and are scheduled for one of the fall meetings this year.

Another activity initiated that will result in a symposium during the 1932 Winter Convention, is suggested by the lack of information reported to the committee on the subject of system operation from the viewpoint of economy and reliability in carrying load schedules. There is considerable literature relating to load division among boilers and generating units in single stations, but new problems in load allocation have resulted from the extensive interconnection of systems previously operating as separate units. It is planned to secure a series of papers describing the practise of at least three of the larger operating systems on which steam generation is exclusively employed, and to reserve the subject of combined steam and hydroelectric sources for later discussion.

The Progress Report which follows, covers the developments of the past two years. Together with a bibliography of the more salient literature on power generation.

RECENT DEVELOPMENTS AND PRESENT STATUS OF POWER GENERATION

Volume and Distribution of Generation

The combination of a two-year drought and the business depression had a marked effect upon the distribution of the total electric generation in the United States between fuel burning and hydroelectric plants. From 1921 and 1928 the average yearly increase in total generation was quite uniform at 11.5 per cent, in fuel generation at 10.9 per cent, and in hydroelectric generation at 12.7 per cent. Applying these average rates to the figures for 1928 there is a calculated deficit at the end of 1930 of 12.1 per cent in total generation, 4.0 per cent in fuel generation, and 32.5 per cent in hydroelectric generation. These figures show that the loss in hydroelectric generation caused by the drought allowed fuel generation almost to hold its normal increase notwithstanding a decrease of 1.5 per cent in total generation in 1930. The total generation in 1930 was 96 billions, of which 34.6 per cent was generated in hydroelectric plants in contrast to 40.4 per cent in 1928.

Generating Plant Building Programs

The added steam generating capacity in the United States in 1929 was secured by about 57 per cent in new plant construction and 43 per cent in additions to existing plants. The total added capacity was nearly 2,250,000 kw. It is interesting to note that in 1930, in spite of the fact that the total electric production for the year was about 1.5 per cent below that of 1929, there was nearly as much steam generating plant capacity added as in 1929, a total of slightly over 2,000,000 kw. This was divided 47 per cent in new plants and 53 per cent in additions to existing plants. Apparently the depression of the past year is to be reflected in the amount of capacity contemplated for 1931 additions, which is about 1,250,000 kw. These additions are mostly in existing plants where the added capacity is 75 per cent of the total, a condition approaching that of 1928, when practically all of the new steam capacity was in additions to existing plants.

Compared to 1928, the number of new hydroelectric plants and the capacity installed in 1929, was strikingly small; the new installations in 1930 were over three times greater than in 1929, but they still were appreciably less than in 1928. The plants now under construction that will be completed in 1931 will total about 50 per cent of the additions to capacity in 1928, while present indications are that the new capacity developed in 1932 will be only a fraction of the 1931 installations. Contrasted to the schedule of immediate construction are the probabilities within the next few years of the super-capacity plants that are being considered on the Columbia, Colorado, and St. Lawrence rivers.

Major Influences in Current Design of Steam-Electric Plants

The fundamental factors influencing the design of modern steam-electric generating plants are about the same as those which dictated design in the past. They are only modified by new and better apparatus now available, such as improved and alloy steels which make possible the use of higher pressures and temperatures, improved fuel burning equipment and furnaces which permit of much higher boiler ratings and greater efficiences, together with numerous other improvements in auxiliary apparatus.

For a number of years the tendency of steam plant investment costs was upward and these increased costs were justified by the considerable improvement in economy. The point has now been reached where improved efficiencies are becoming increasingly difficult to secure, and any increase in capital cost is difficult to justify. It would seem, therefore, that the effort to lower production costs must lie in reductions in capital investment through simplified design, raising the output of the equipment, and increasing the capacity for a given unit of space.

Probably the most attractive feature in a program of simplification is the possibility of reducing the number of boiler units for a given turbo generator output. Reports published within the last year indicate that the modern boiler has a reliability factor practically equal to that of the turbo generator. It would, therefore, seem that spare boiler capacity should be considerably reduced over past practise up to the point where boiler and turbine capacity would be equal. In other words, the boiler and turbine might be considered as one complete unit. This would be particularly practical where there are several units in the same station, in which case a certain degree of flexibility could be secured where a boiler and turbine forming separate units might be out of service, in the one case for boiler inspection or repairs and in the other case for turbine inspection or repairs.

The greater cleanliness in the operation of fuel preparation and feeding apparatus will now permit the installation of turbines, boilers, and fuel equipment in single buildings without the use of the dividing walls which have up to this time been considered necessary. There has been a number of instances where plants have been constructed without these walls and are giving very satisfactory operating results. The omission of dividing walls not only saves the cost of the wall but reduces the amount of building steel and permits of a more compact arrangement of apparatus, thus bringing about a natural reduction in the cubic contents of the building. In certain cases a reduction in operating labor has also been secured.

Outdoor installations of boilers, turbines, and electrical equipment are advocated by some engineers and many attractive studies have been brought forth. To date, however, no large outdoor installations have been projected. While such installations are not in entire favor with operating engineers the reduced investment has made the designs of interest.

In practically all of the older designs there was a great deal of duplication in the piping layouts. Numerous cross connections, loops and sectionalizing valves were used, partly with the idea of protecting against failure of any part of the piping system and partly due to the desire to protect against failure of apparatus used in the feed-water heating cycle. Experience with operation of piping, valves, and equipment has shown that their factor of reliability is, in general, as great as that of the turbines and boilers. The opinion has frequently been expressed that provisions made for cross-connecting and sectionalizing have never been used even though they have been in the plant for a considerable number of years. Simplification of piping design and reduction in number of valves, joints, etc., would reduce both the capital expenditure and the operating cost.

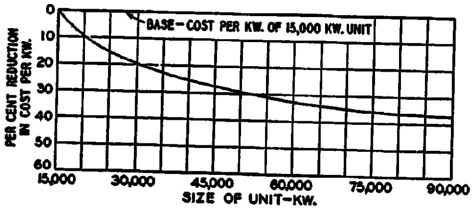

FIG. 1—PER CENT REDUCTION IN UNIT COST OF SINGLE SHAFT TURBO-GENERATOR UNITS DESIGNED FOR 450 LB. 775 DEG. FAHR. STEAM

Considerable thought has been given to reducing the number of duplications of auxiliary equipment, such as condensate, air and circulating pumps for turbo generator units. In designs where several spare boilers were provided it was the practise to install single auxiliaries such as stoker drives, forced and induced draft fans, whereas on the turbo generator units it was customary to duplicate the auxiliary equipment. With the present consideration being given to reduction and possible elimination of spare boilers, the question of duplication of auxiliaries should be carefully considered. The usual argument that it is good insurance to protect the large unit by the installation of duplicate and comparatively cheap auxiliaries, carries some weight. Against this, however, must be balanced the lower capital and operating costs by minimizing the number of pieces of apparatus and simplifying the piping design.

The use of larger units, both boilers and turbines, has resulted in a lower unit cost of equipment and in a marked reduction in the cost of the building per kilowatt of capacity. There is a number of installations either already made or pending, where the capacity of the new turbo-generator unit is from two to three times that of the unit for which the building was originally planned. It is evident, therefore, that the cost of this portion of the building per kilowatt would be reduced to one-half or one-third of the original cost. A few years ago the cost of buildings per kilowatt of capacity was roughly $30. It is, therefore, evident that the possible savings in building alone due to use of larger equipment results in a material reduction in cost per kilowatt. This would have a particular application where equipment is to be installed in a vacant space in an existing building or where it is desired to increase the capacity by replacing equipment in an old plant which is strategically located in the distribution system.

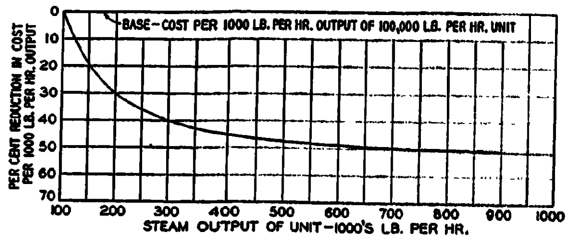

FIG. 2—PER CENT REDUCTION IN COST OF BOILER UNITS DESIGNED FOR 450 LB. 775 DEG. FAHR. STEAM

Prices used in plotting the curve include cost of boiler, superheater, soot blowers, air heater economizer, and pulverized fuel equipment

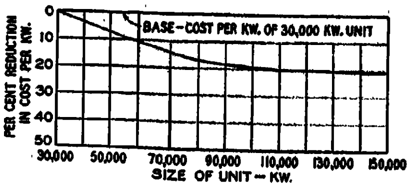

FIG. 3—PER CENT REDUCTION IN COST OF SINGLE SHAFT TURBO-GENERATOR UNITS DESIGNED FOR 1,000 LB. 775 DEG. FAHR. STEAM REHEATED TO 775 DEG. FAHR.

The reduction in floor area has assumed importance not only from the standpoint of building and land value but from the resulting reduction in cost of much of the piping and auxiliary equipment. In order to reduce the floor area some of the modern designs resorted to the vertical compounding of units as typified by the Jersey Central Power and Light Company and the Pacific Gas and Electric Company where a high pressure turbine and generator are mounted on top of a low-pressure generator. By such means and by the increase in the maximum size of turbines from 50,000 kw. in 1920 to 200,000 kw. at present, the floor area has been reduced from an average of 42 sq. ft. per installed kilowatt to less than half that area.

Typical of this trend are the Ford Company in which a 110,000-kw. unit is to be installed where one 12,500-kw. unit is being removed; the Hell Gate Station of The United Electric Light and Power Company where two 160,000-kw. units have been installed in the space designed for two 35,000-kw. units and the Hudson Avenue Station of The Brooklyn Edison Company, Inc., where two 160,000-kw. units have been purchased for the space designed for two 50,000-kw. units.

Along with the increase in size of turbines the weight per kilowatt including the generator has been reduced in the past ten years from about 28 lb. to 15 lb.

The curves in Figs. 1, 2, and 3 will give an indication of the trend toward lower costs with increased size of turbo generators and boilers per unit of capacity. Figs. 1 and 2 represent respectively cost trends for turbo generator and boiler units designed for 450 lb. pressure and 775 deg. fahr. total temperature. Fig. 3 is representative of a compound single-shaft turbo generator where the initial steam condition would be 1,200 kw. and 775 deg. fahr. total temperature, with steam bled at 400 lb. and reheated to the initial temperature.

Along a line totally different from the selection and arrangement of equipment, and also for the purpose of reducing the cost of power generation, has been the cooperative interconnections adopted in the last few years between steam-electric stations and industrial plants. The latter in some cases require large quantities of steam under conditions that may or may not be suitable for the supply of power necessities; in other cases the industrial plants may have the disposal of byproduct fuel either solid or gaseous. It has been found advantageous to both parties in a variety of industries to arrange both electric and steam interconnections whereby power and steam are generated in the most economical fashion, and the fullest benefit derived from diversity in power, steam, and byproduct conditions. In many instances the electric plant supplies both steam and electricity, requiring certain modifications in the standard feed water system. Recent literature has described such arrangements at Deepwater, New Jersey, Rochester, New York, Toledo, Ohio, Baton Rouge, Louisiana, Mobile, Alabama, and Cedar Rapids, Iowa.

Factors at Present Determining Maximum Size of Boilers and Turbines

While large unit size turbo generators reduce the cost per installed kilowatt they sometimes represent a greater capital charge for reserve capacity. A check of available published information regarding peak loads and installed capacity in fourteen large central station systems indicates the following reserve capacity in per cent of the total installed:

Four systems were between 30 and 36 per cent.
Seven systems were between 20 and 30 per cent.
One system was about 17 per cent.
Two were less than 10 per cent.

The same published information indicates that the two systems having the smallest reserve capacity have a substantial percentage of purchased power, so that it is very probable that actual reserve capacity would be materially increased by available spare capacity through interconnection. In one of these systems, where the per cent of reserve capacity is the greatest, it is known that the generator capacity reported on was not all available at the time the tabulation was made, since the boiler capacity in one of the principal plants limited its capacity to a point considerably below the generator name plate ratings. The selection of the very large units in some of the recent developments may have been due to a program of interconnection or expansion which it was estimated would occur within a few years following the installation of the new machine.

Allowance must be made for the loss of the largest unit during operation and also for the possibility of its being out for repairs. If, therefore, units are purchased out of proportion to the size of the system there is likely to result an over-all economic loss. Large units show better performance at comparatively heavy loads. Due to the system reserve requirements it may be necessary to operate at a relatively light load where the economy is poorer. Even the smaller units operating may be affected the same way from the fact of the larger units being on the system. With large units the total amount of auxiliary power requirements for any given system output will also be increased at low system loads. With a large unit carrying heavy load a greater system disturbance would result if the unit should suddenly trip out. Other things being equal the time required for starting a large unit is greater than for one of smaller size.

Transportation difficulties for damaged parts, a longer time necessary for repairs, and larger floor area necessary for dismantling are some of the factors which must be weighed against the lower unit investment and lower labor charges.

Turbine manufacturers have indicated that up to 200,000-kw. capacity in single shaft machines would be feasible. By compounding on multiple shafts the limits, of course, would be considerably higher. One of the limiting features in size would be in connection with the generator and here the use of double windings or raising the voltage will offer a partial solution of the electrical problems.

The limitations to the building of large boilers are more structural than economic. Since at present larger capacity is concentrated in single turbines than in single boilers the problem of boiler reserve is of less importance. Also the experience with pulverized fuel boilers having capacities in the neighborhood of

1,000,000 lb. of steam per hour indicates an availability factor during demand periods approaching 100 per cent.

Large boilers have an exceedingly flat efficiency curve and can be operated at relatively low loads at efficiencies equal to that obtainable from boilers of smaller size. The parts involved in boiler construction are small and do not involve any transportation problems.

Rehabilitation of Existing Steam Plants

Many studies are still being made by steam station designers to increase station capacity by means of improved thermal cycles using higher temperatures and pressures, but not much actual revamping has taken place in the past year or so because of the falling off in power station demand and construction. Then again, while many studies of rehabilitation have been made, all recent improvements in steam station design have been quite broad in their application involving considerable major equipment. Generally speaking, where there has been a demand for increased capacity it has been for such large increments that invariably more consideration is given to the building of new stations with units of large capacity than to some modification of existing generating facilities.

Some steps looking to improved steaming have been taken, such as the installation of water-cooled walls frequently combined with pulverized fuel firing with resultant greater output from the same boiler; also, the installation of air-heaters resulting in a reduction of stack losses. Recent studies made on binary cycles indicate that improvements in efficiency can be made in old plants employing old boilers.

The important recent developments of interest to steam station designers both in the United States and abroad which will, no doubt, in the future have a great influence on rehabilitation, have been:

a. The installation of a 10,000-kw. mercury turbine in the South Meadow Station, Hartford, Connecticut.

b. The installation of high-pressure steam (750 lb.-2,800 lb.) units at Langerbrugge Power Station in Belgium.

c. The construction of new peak load plants in Germany of low pressures.

d. The construction of heat storage plants in Germany.

Rather than follow these lines of securing an increase in capacity and improvements of economy by changes in old stations, the trend in American practise is, with a few exceptions, more along the lines of building new efficient high-pressure steam plants and utilizing interconnections to a greater degree for permitting the operation of the new stations at high capacity factors on base load, and retaining the older less efficient stations for peak loads. With ample interconnections, addition of new capacity at old load centers is not often thought to be as economically advantageous, everything considered, as establishing new generating points where ample land, rail, and water facilities are available.

Reduction in Operating Costs of Steam-Electric Plants

The production of electricity from steam central stations has developed so remarkably in the last decade that it seems fitting in this report to review the progress that has been made during this time.

The average unit production cost has decreased about 50 per cent. The heat consumption per kilowatt hour has been reduced from about 30,000 B. t. u. in 1920 with a best record of 18,000, to an average of 18,500 B. t. u. in 1930 with the best record approximating 12,500 B. t. u. This is for stations using steam only. The mercury steam cycle installation at the South Meadow Station of the Hartford Electric Light and Power Company reports an average heat consumption of around 10,500 B. t. u. per kw-hr.

The progressive increase in the size of turbo generator and boiler units together with the improvements that have resulted in the reduction of supervisory requirements have brought about a constant decrease in labor costs. Great improvement has been made in control equipment with the consequent extension of the scope of supervision of individual operators.

Boiler maintenance costs have been reduced by the use of cooled furnace walls and from the studies by engineers of the effect of operating conditions on maintenance, with a consequent increase in availability of equipment.

Allocation of the load to various stations of a system on a basis which gives a minimum combined cost for each momentary change in load demand and at the same time taking into consideration the effect of loading on the maintenance of equipment, losses incidental to starting and labor costs, has brought about a great reduction in operating costs.

For example, for any particular load demand on the system there is one combination of units and loads at the various stations which will give the lowest combined cost for the system. The determination of this equipment set-up is made by grouping various combinations of units at the different stations through the use of cost input-load output and incremental cost characteristics of the units.

These cost input-load output and incremental cost characteristics are computed from tests on the equipment and it is very important that these tests be obtained with a high degree of accuracy. An operating factor based on a knowledge of the performance of the unit under normal conditions of operation is applied in order to obtain the true normal operating characteristic of the unit. The amount of equipment and location of equipment operating at the various stations must in all cases conform to the standard system operation reliability, which takes into consideration such factors as physical layout, storms, voltage regulation, and protection of the load.

With the determination of the amount of equipment operating at the various stations any change in system demand will be made on the basis of the station incremental cost curves for the equipment operating to a point at which it becomes more economical to operate on another set-up. This method of loading for every momentary change in demand gives a minimum cost for all ranges of load, limits the number of units operating to those required for economy and reliability, and results in a greater utilization of the more efficient units.

In the case of one large power system during the last year the generating capacity of the system was increased about 2 per cent whereas the output delivered by the newer units was raised 13 per cent. As a matter of fact on that system during the year 1930 considerably more kilowatt hours were generated than in 1929 at a total production cost lower than that of 1929.

Table I shows the actual operating results obtained from several different types of stations. The low heat rate obtained by Station A indicates the possibility of a greater adoption of the mercury steam turbine in the near future.

TABLE I—RECENT OPERATING RESULTS

Station	Pressure lb./sq. in.	Temperature deg. fahr.	Cycle	Load factor per cent	Period	Heat rate B. t. u./net kw-hr.
A	70	884	Mercury		Dec.-Feb. 1930	10,180

H	250 400	700	Regenerative	59.3	Oct. 1930	15,712

Technical Developments in Steam-Electric Plant Design

The seven high-pressure stations described in the last report have been in operation long enough to confirm the results expected from them. Excepting continuing trouble with boiler feed pumps in some of the plants, no unsolved difficulties have been encountered. The more prominent additions to the list of high-pressure plants within the past two years have been the State Line plant near Chicago, the River Rouge plant of the Ford Motor Company in Detroit, and the Port Washington plant of the Milwaukee Railway and Light Company.

State Line plant, described in previous reports, was placed in operation in 1929 with a single three-element turbo-generator unit of 208,000-kw. capacity. The initial steam conditions were 630-lb. pressure and 730 deg. fahr. The extension to the plant now under construction includes two single shaft units of 150,000- and 125,000-kw. capacity respectively. The steam conditions will be 1,200 lb. and 825 deg. fahr., using boilers fired with pulverized coal from unit type mills. An interesting feature in connection with the turbines will be the reheating of steam from the high-pressure cylinder to 825 deg. fahr. at 400 lb. pressure, and its reintroduction into the high-pressure cylinder for expansion to the cross-over pressure of 15 lb. absolute. Reheating will be done in boilers of the reheat type.

River Rouge plant starts operation this year of the very interesting steeple compound 110,000-kw. turbo generator. The initial steam condition is 1,200 lb. at 750 deg. fahr. Live steam reheaters will raise the temperature of exhaust steam from the high-pressure element to 550 deg. fahr. at 80 lb. absolute pressure before it enters the low pressure element. Of particular interest is the fact that this new machine is installed in space originally occupied by two 12,500-kw. turbines and sufficient space will remain for the addition of a second 110,000-kw. unit of the same type at a later date. Two boilers, each having a maximum steam capacity of 700,000 lb. per hour, will serve this turbine.

The Port Washington plant will have one boiler of 690,000 lb. of steam per hr. to operate at 1,300 lb. pressure and initial and reheat steam temperatures of 825 deg. fahr.

In the realm of boilers for pressures above 1,400 lb. there has been no development except in that of size. The Benson and Loeffler boilers are now being built in Europe in capacities above 100,000 lb. of steam per hour; three Loeffler boilers, each with a designed output of 150,000 lb. of steam per hour at 1,850-lb. pressure and 932 deg. fahr. have recently been ordered for a plant in Czechoslovakia. The Benson boiler in use at the Langerbrugge plant in Belgium produces 220,000 lb. of steam per hour at 2,270-lb. pressure. An experimental boiler to operate at 3,200 lb. pressure, being installed at Purdue University, will be the first at that pressure in America. Boilers for 1,800 lb. pressure to supply steam to two 6,400-hp. triple expansion engines are now in course of erection at the Philip Carey plant in Cincinnati. The design of European types of high-pressure boilers was reviewed in the 1929 report.

There is some evidence that the average steam temperature in large power plants in this country has increased slightly during the past two years, and the maximum temperature in use is now considered to be approaching 800 deg. fahr. The Langerbrugge plant in Belgium has operated at a temperature of 850 deg. fahr., for 4½ years and in general there is more of a tendency to use extremely high temperatures in Europe than in this country. In certain respects modern European boiler designs lend themselves to the generation of high temperature steam, and the practise of multi-barrel turbines, common in Europe, is also adaptable to its use. In the United States the Detroit Edison Company has recently put into operation a 10,000-kw. turbo generator at its Delray No. 3 plant, designed to use steam at 1,000 deg. fahr. At the present time the turbine is operating on steam from the station main under 400 lb. pressure and at 750 deg. fahr. For high temperature operation the supply steam will be passed through a separately fired superheater using oil for fuel. The steam main between the superheater and turbine is provided with several types of pipe joints, and other arrangements have been made to note the effect of the high temperature upon the piping, turbine, and superheater, so that the installation constitutes in reality a full scale experimental investigation.

During the past two years the mercury vapor boiler and 10,000-kw. turbine installation of the Hartford Electric Light Company has been perfected to the point where it was available for 82.3 per cent of a period covering 7,520 hours. Excluding causes arising from the use of mercury, the installation would have been available 95.1 per cent of the time. The average thermal rate was 10,310 B. t. u. per net kw-hr. Of the total energy generated, 42.5 per cent was produced by the mercury turbo generator, and the remainder by the steam formed in the mercury condenser.

As a result of the experience at Hartford, mercury vapor units of 20,000-kw. capacity each are being planned for the Kearney plant of the Public Service Corporation of New Jersey and for the power plant of the General Electric Company at Schenectady. The latter installation and an associated steam boiler will be one of the first outdoor steam plants. The mercury vapor pressure will be increased to 125 lb. per sq. in. in these new units, and it is expected that a thermal rate of 8,800 B. t. u. per net kw-hr. will be secured at a load of 20,000 kilowatts on the mercury turbine and with the power developed from the 240,000 lb. of steam per hr. produced at 400 lb. pressure in the mercury condenser.

Higher steam pressures and investigations of troubles resulting from caustic embrittlement have indicated the desirability of boiler drums without seams. Forged drums have been used exclusively for the 1,400-lb. boilers, and lately hammer-welded drums for medium pressure boilers such as the four drum boilers in the James H. Reed Station of the Duquesne Light Company in Pittsburgh, that operate at 400 lb. pressure. The possibilities of fusion welded boiler drums have been studied intensively in the past two years, and "Proposed Specifications for Fusion Welding of Drums or Shells of Power Boilers" were published in the March 1931 issue of *Mechanical Engineering.* The Boiler Construction Code does not at present permit fusion welding of parts where the safety of the structure is dependent on the strength of the weld.

While no boiler installations have been made of rger capacity than those in the East River and Hell Gate plants in New York that were described in the last report, operating experience at the East River plant has shown that loads can be carried on the boilers there considerably in excess of the expected capacity. A unit generation of 1,250,000 lb. of steam per hour has been maintained, the actual operating limit being met in the capacity of the steam piping leading from the boiler unit. A boiler of 1,000,000 lb. per hr. capacity was recently installed in the Kips Bay plant of the New York Steam Corporation on a floor area originally allotted in 1926 for a boiler of half the output. These large boilers are in reality twin-set boilers having two independent water circulating systems and steam uptake connections, located over a common furnace. The largest single boiler to date has a capacity of about 600,000 lb. of steam per hour.

The installation of boilers of large capacity has focused the attention of operating and designing engineers upon the problem of boiler availability. Although in most plants the number of boilers still exceeds the number of turbo generators, boiler outage in many cases impairs to some extent a plant's generating capacity. Protection of the furnace walls with water cooling surface, improved reliability of the coal feeding and burning equipment, as well as of the ash handling apparatus, increased attention to the details of the auxiliary apparatus, and correct boiler water conditions, have resulted in numerous instances of boiler availability equal to that of turbo generators. The first statistical study of this subject on a large scale was directed in 1929 and 1930 by Mr. C. F. Hirshfeld of this Committee, and was published in *Transactions,* A. S. M. E., Vol. 52, No. 27, p. 265. The data compiled covered only a year and there were several other reasons why the statistics were necessarily inconclusive, but they seemed to indicate that the details of design and construction and operating skill are more important in obtaining high boiler availability than such matters as rate of output per unit of surface, type of fuel, and method of firing. The average availability factor appeared to be between 84 and 90 per cent.

During the period being reviewed, the point of major technical interest in connection with the pulverized coal method of combustion has been the long-time comparisons in the same plant of the unit and bin systems. No generally accepted opinion regarding their merits has been reached. Both systems were installed in the Deepwater plant, New Jersey, where it has been reported that the unit method of firing gave a higher efficiency but a lower reliability. Other comparative studies have been recently published for central stations in Chicago and St. Louis.

Experimentation has continued with the slag tap type of furnace for pulverized coal firing, and its use has been extended. The major difficulty has been the gradual expansion in a horizontal plane of the furnace floor, with consequent bulging of the furnace walls. This results from penetration of the hearth bed by the molten slag, through cracks formed when the furnace is cooled during boiler shutdowns.

The size and total fuel burning capacity of underfeed stokers continue to increase, and steam outputs per boiler of 500,000 lb. per hr. are now possible with stoker firing. There has been only a foot increase in the maximum width of stokers in the last ten years, but the length has been increased from about 13 ft. to 26 ft. 7 in. The largest underfeed stoker in this country is now being installed in the Hudson Avenue plant of the Brooklyn Edison Company, and will be 26 ft. 7 in. long by 26 ft. wide, with a grate area of 694 sq. ft. Stokers of this size have been made possible by extensive cooling of the furnace walls by water cooled surface, improved coal feeding and distributing mechanism, and better control of the air distribution to the several parts of the grate surface and ash pit. In come cases automatic control of the air distribution has been installed. Rotary ash dischargers are almost standard for the larger size of stokers.

Although the fuel burning capacity of stokers per foot of width has been greatly increased, there has been no increase in the rate of combustion per square foot of total grate surface, which is limited by the possibility of clinkering and the blowing of coal from the firebed. Neither has there been any modification of the fact that the combustion rate depends upon the type or burning characteristics of the coal burned. Maximum rates of 60 to 70 lb. per sq. ft. for 10 hour periods have been maintained with good quality eastern coals; 50 to 60 lb. with coals from the central field. Slack coal reduces the maximum rate to the neighborhood of 40 lb. per sq. ft. With all coals an increase in the combustion rate results in an increased loss from incomplete combustion, cinders, soot, ash pit, radiation and unaccounted for losses, in some reported tests these losses reaching a value of 20 per cent.

The limiting temperature for preheated air with underfeed stokers seems to be in the neighborhood of 350 to 400 deg. fahr. Although some installations have attempted to use higher temperatures, it has been found that the stoker maintenance has been adversely affected.

The installation of large turbo generators has continued although no units have been projected larger than those mentioned in the last report. The largest machines now on order are two 160,000-kw. units for the Hudson Avenue plant of the Brooklyn Edison Company. It is noteworthy that all of the turbo generators except one, that are now on order in sizes greater than 100,000 kilowatts, are of the tandem compound type. The exception is the 110,000-kw. high-pressure vertical-compound machine for the Ford Motor Company. The development of generators of large capacity was an essential to the use of tandem-compound turbines.

The record in capacity for single cylinder turbines operating at 1,800 rev. per min. is now carried by two 80,000-kw. turbo generators in the Charles R. Huntley station of the Buffalo General Electric Company. Steam supply to these units is at 435 lb. and 750 deg. fahr.

In the field of high-speed turbo generators, single cylinder condensing units are now in operation in the United States up to 10,000-kw. at 3,600 r. p. m., and tandem-compound units at the same speed up to 15,000 kw. A 15,000-kw. single-cylinder condensing unit of English manufacture has recently been installed in Canada and the C. A. Parsons & Company are willing to build single-cylinder units of 25,000-kw. capacity to operate at 3,600 r. p. m.

Intensive study in turbine design is being made in connection with the use of higher steam temperatures. This problem as well as that of blade erosion is a matter of metallurgy, and the developments to date indicate that it will soon be possible to operate turbines at initial steam pressures above 500 lb. without the necessity of reheating. At the present time a 60,000-kw. unit has been built to use steam at 650 lb. and 825 deg. fahr., and illustrates the simplification and turbine arrangements that will be possible when higher steam temperatures are available.

High-Voltage Generators

There has been a significant demand for generator units of larger and larger capacities, and while this has possibly been the condition since the beginning of power station construction it appears to advance by periods with the most recent one occurring within the past five years. With an increase in generator capacity the designing engineers have been faced with the problem of providing suitable and reliable insulation, conductors, supports, and terminals both internal and external to the machines. Machines of larger capacity for a given voltage mean greater currents. Greater currents mean larger conductors, and consequently greater weights to support normally and greater stresses to provide for at times of short circuits. With the greater currents other external difficulties also arise, such as the provision for the installation of large cables if the power is taken away in underground cables, the reduced carrying capacity of the cables if many are required in restricted spaces, and the provisions necessary to nullify the effect of the sheath voltages. Consequently there has been a very natural trend to higher generator voltage and to multiple-winding machines to reduce the amount of current per conductor.

Unless it is necessary to consider generation at a pre-established voltage and the distribution problems connected therewith, in other words, if generation alone, is to be considered, the most economical voltage usually increases slightly with the increase in the size of the unit. From the generator manufacturer's standpoint, for generators of 100,000 kw. or more, voltages in the neighborhood of 16,000 to 18,000 volts are reported to result in the most economical design. In some instances, economics dictate machines within this range of voltage with transformers for stepping up to the desired transmission voltage, so that, where the generator voltages are not well established, it might be said that for machines above 100,000 kw., the present trend is toward the use of multiple-winding machines with transformers or auto-transformers, rather than to higher voltage machines. The trend will no doubt continue toward multiple-winding machines until the point in capacity is reached when it will prove more economical to increase the voltage.

Some attempts have been made to standardize on generator voltages above 13,800 volts, but since the introduction of successful multiple-winding machines, the study and demand for higher standard voltages has not been so insistent, and may be said to be dormant for the time being. In other words, the double-winding design has made it possible to increase the capacity without increasing the voltage, and to postpone the day when it will be necessary to go to higher voltage. It is not at all unlikely that in the future, generators will be built with more than two windings. The principal difficulty with more than one winding, is in finding sufficient space at the terminals of the machine windings, to install potheads and make connections with satisfactory clearances.

Within the past three years there have been installed in the territory adjacent to Chicago, and there are now in operation, seven 22,000-volt generators with a combined generating capacity of 474,000 kw., ranging in size from 52,500 kw. to 105,000 kw. Additional 22,000-volt generators totaling 432,000 kw., and one 18,000 volt, 115,000-kw. generator are on order for this territory, to be installed during the years 1931-1932.

Outside of the above there have been but four steam-driven generators placed on order or installed recently in this country for voltage ratings above 13,800 volts, namely:

Two 160,000-kw., 16,500-volt units for the Brooklyn Edison Co., and

Two 94,000-kw., 16,500-volt units for the Southern California Edison Company.

Abroad, the outstanding recent high-voltage installations which will be watched with considerable interest are the two 33,000-volt, 25,000-kw., 3,000-r. p. m. generators at Brimsdown, England, and the 36,000-volt, 25,000-kw., 3,000-r. p. m. generator at Langerbrugge, Belgium.

Switch Structures, Switching, and Control

The housing of major switching in both congested and open localities is receiving much study, particularly new installations, because of the advent of metal-clad switchgear. There has been a marked increase in and trend toward the use of metal-clad switchgear in place of indoor cell type and outdoor open type bus structures. Many hundred indoor and outdoor type metal-clad combined switch and bus units of American design are now in service, some with air and some with oil-filled metal enclosed bus compartments.

The first installation in this country, and possibly in the world, of high-voltage outdoor metal-clad switchgear was the 33-kv. substation of the Public Service Company of Northern Illinois, at Wheaton, Illinois. This has been in service since March 1928. Since then there have been many other installations which embody improvements in design and manufacture. This type of switchgear can now be obtained in practically all capacities for which circuit breakers have been developed, including 132 kv. One 132-kv. installation is now being made. The earlier large units involved a considerable amount of field assembly. The latest designs permit complete factory assembly and testing of very large capacity units, such as a full double bus section for one circuit, complete with instrument transformers, buses, etc., for breakers of 22-kv., 3,000-amperes, 2,500,000-kva. interrupting capacity. These units are shipped completely assembled and oil filled thereby entailing a minimum of field assembly and installation work, and avoiding the necessity of drying out, reconditioning, etc., by purchaser.

In the case of several generating stations it has been found that an outdoor oil-filled metal-clad switchgear structure could be installed cheaper than an isolated or separated phase indoor cell structure if the cost of the building is taken into consideration; in some cases a saving as high as 20 per cent has been indicated. Other companies report the reverse where installation conditions are different. One company has proved by actual cost data that for 33-kv. substations the total over-all cost of metal-clad outdoor switchgear erected and ready for service, compares favorably with that of the conventional open type formerly used. This latter comparison, however, would not yet hold for all conditions and localities.

Additional advantages to be gained from complete factory built equipment are the saving in space, the salvage value in case of replacement or rearrangement, and the much greater safeguards to operators and service.

There is a growing demand for faster operation of circuit breakers in case of fault. The manufacturers have made considerable progress toward meeting this condition in the design of circuit breaker operating mechanisms and contacts and methods of extinguishing the arc as well as in the high-speed relay designs. Tests have shown repeated operations where the arcing time was as low as one to two cycles. Large breakers are now available with a conservative over-all time rating of eight cycles. In view of these developments it is quite possible a more severe duty cycle than the 2-OCO may be considered for the rating of oil circuit breakers.

The interest indicated in locating equipment outdoors is not confined entirely to switchgear. There are a few instances where large rotating units have been installed outdoors, and the subject is being given much study.

There has been an increase in the tendency toward the use of steel switchboard panels and the use of hinged panels or cubicals. The desirability of smaller switchboards in the larger power stations and substations is also receiving attention. Various attempts have been made to use miniature equipment, and a smaller number of items, and combination units of instruments and relays. At the same time there is a growing demand for more relays and instruments for one purpose or another. The supervisory system of control seems to be arousing more and more interest as a means of condensing or consolidating the control of a large number of circuits within the convenient reach of a single operator.

The so-called distance relays are becoming more popular. The automatic synchronizing, automatic frequency, and automatic load division control are receiving more attention. Although the first has been available for a number of years, the latter are more recent developments and it is quite possible that the demand for both may grow.

If the predictions indicated in recent announcements with reference to vacuum tube developments, such as the "thyratron," may be anticipated, we are about to see some very wonderful and radical changes in the entire scheme of station control, switching, transformation, transmission and control station design in general. To what extent and how rapidly this may take place is at present problematical. The possibilities we must admit, however, are tremendous. Already there have been some novel commercial applications and very promising laboratory tests extending over a considerable period.

A new type of adjustable-speed control for a-c. motor drive is now available, permitting practically a straight line speed curve with infinitely small steps from zero to maximum. The drive can be installed at nearly the same cost as the drives previously used. The method of control permits high efficiency which in some cases shows a considerable saving over any other type of control. The drive will maintain constant speed regardless of load, is simple, permits the use of standard electrical design features, and to a considerable extent, standard machine parts. To date the service applications have been confined to boiler draft fans and boiler feed pumps, but the drive is adaptable to many other services where fine speed adjustments, and simplicity of operation with high efficiency, are important factors. Thirty-five of these equipments were ordered in 1930, some of which have now been in service for several months. For those who are not familiar with the "Rossman Drive" system it may be of interest to state it consists primarily of an induction motor of standard design, except that the mechanical construction is modified to permit what would be the stator to revolve. This revolving stator is connected by texrope or other means, to a smaller standard d-c. machine fed from a standard motor-generator set or other d-c. source. The speed of the small d-c. machine is controlled by adjusting the voltage impressed on its armature by the generator of the motor-generator set. This may or may not be supplemented by field control. By varying the speed and direction of rotation of the d-c. machine, the load may be driven at any speed within the design range.

Factors at Present Affecting Hydroelectric Development

The increasing attention directed to the large-scale hydro developments on the Colorado and St. Lawrence rivers by governmental agencies is perhaps a new factor influencing the trend of hydroelectric installations. At the same time the federal waterpower licensing policies are being questioned and subject to criticism by both private and political interests, and both have been coincident with severe drought during the past two years in many parts of the country. The complementary value of hydro and steam power sources on systems supplied mainly by hydro has been fully realized, and the principal hydroelectric systems on the Pacific Coast, in the southeastern states, in New England, and in the vicinity of Niagara Falls, have either put into operation during the last two years steam plants of large ultimate capacity or have affected large capacity ties with existing steam plants in adjacent territory. The recent availability of low cost gas and oil fuels in the West, and the advances made in the thermal efficiency of large boilers and turbines, combined with their attractive investment costs, are causing a pronounced predominance there of steam-electric installations that will continue for an unknown period. In the East and South the necessity of steam reserves for low-flow periods has accelerated steam expansion programs. At Niagara the entire water diversion permitted under the existing treaty is utilized and the load growth necessarily must be assumed by steam generation.

Type of Steam Plants on Hydroelectric Systems

A marked similarity in certain design features is noticeable in all of the new steam plants supplementing power systems hitherto dependent upon hydro generation. Gas and oil are the outstanding fuels in the West, while in the East pulverized coal exclusively is fired. Boiler capacities range from 400,000 to 550,000 lb. of steam per hr. at pressures between 425 to 475 lb. per sq. in. with the exception of one plant on the Pacific Coast operating at 1,300 lb. per sq. in. Turbine capacities vary from 40,000 kw. up to 100,000 kw., and one to three boilers are installed per turbine, the usual number being two. The selection of pulverized coal firing appears to be made for reasons other than the emergency starting of boilers; and in fact extra facilities for standby operation of turbines and boilers are provided in only one of the recent plants, which operates on a system where steam generation will be a minimum yet service demands require continuous availability of the steam-electric generator.

General Features of Recent Hydroelectric Development

No hydroelectric plants of unusual total capacities have been put into operation during the past two years, although there have been one or two new records for turbines of large physical dimensions, and the three 49,000-hp. Francis units in the Waterville plant in North Carolina surpass in capacity all previous units of that type operating under high heads. An unusual construction procedure was adopted for the Chute-a-Caron plant on the Saguenay River in Canada. The preliminary drawings for the Boulder Dam plant on the Colorado River reveal no unusual features except the height of the dam and the contemplated power capacity. The Spier Falls plant on the Hudson River is an interesting example of rehabilitation and design investigation by means of model tests. In fact the increasing use of model testing, and its application to the design of the propeller type turbine wheel, constitute the outstanding technical advance in this country in hydroelectric practise during the past two years.

Propeller Turbine Development and Model Testing

Notable installations of propeller turbines of the fixed and manually adjustable blade types were in operation or approaching completion in 1928, and one small capacity wheel of the automatically adjustable type, the Kaplan turbine, was in the course of erection. Since 1928 there have been numerous installations in America of small capacity Kaplan type propeller turbines, that have been designed and installed under European licenses. The Kaplan turbine was first developed in Europe where there are now some large capacity wheels in operation. It is essentially suitable for low-head developments, being used for heads up to about 70 ft. European designs of the fixed blade and Kaplan turbines have been based upon extensive model testing of the turbine wheels as well as of the associated inlet casings and draft tubes.

One of the principal objects of testing models of propeller type wheels has been to determine the limiting conditions of cavitation, for which adjustable draft head conditions are required in the test laboratory. Cavitation, or the formation of bubbles of vapor and air in low-pressure areas adjacent to the runner surfaces, causes a drop of wheel efficiency, but its most prominent effect is the rapid disintegration of the runner material. Cavitation pitting had been encountered in this country with Francis type wheels under certain conditions of specific speed and draft head, and an amount of field experience has been accumulated by which proper operating conditions can be selected for Francis wheel installations. One of the chief advantages of the propeller turbine is the higher specific speed that is possible, but as field data were lacking for such operation, it was considered essential in Europe to determine the optimum installation conditions in advance of construction by means of cavitation testing. Following such investigations propeller turbines of record dimensions, horsepower, and water discharge capacity have recently been installed in the Ryborg-Schworstadt and Kembs plants on the Rhine River in Europe. Pertinent data about these plants are as follows:

Plant	Ryborg-Schworstadt	Kembs
Type of runner	Kaplan	Fixed blade propeller
Number of units	4	5
Head in feet	35	54
Turbine rating-horsepower	35,000	36,000
Water discharge-cu. ft. per sec	10,500	6,800
Rev. per min	75	94
Runner diameter-inches	276	220.8

Cavitation laboratories have been built during the past year, one or two in the United States and one in Canada, for the investigation of design problems concerning propeller type wheels. The construction of a national Federal hydraulic laboratory has also been recently authorized; model testing has been done extensively at one of the technical colleges in the United States for the design of dam spillways, water courses, and turbine settings, and two or three other colleges and individual companies have done a certain amount of such investigation. The first large plant in this country to install automatically adjustable blade propeller turbines is now being built at Safe Harbor on the Susquehanna River in accordance with data obtained from cavitation and wheel setting tests. Six turbines having a rating of 42,500 hp. each at a gross head of 55 ft. are being installed initially. The wheels will have a diameter of 220 in., a water discharge of 8,000 cu. ft. per sec. at rated head and output, and will operate at 109.1 rev. per min.

Briefly described the Kaplan turbine consists of a propeller, or axial flow turbine, whose blade angle is controlled by the speed responsive governor that controls the turbine wicket gates. Separate servo-motors are provided for operating the blades and gates, and a cam is used in the governing mechanism to direct the movement of the runner blades according to the movement or position of the wicket gates. The servo-motor for operating the runner blades forms part of the turbine shaft, and is usually located just under the generator coupling. The links and crank arms for moving the blades are enclosed in the runner hub.

By automatically maintaining the correct relation of blade position to gate opening, the peak efficiencies of a series of propeller wheels each having the proper blade angle for a particular turbine load, are secured, with the result that the efficiency-horsepower curve of such a turbine is quite flat compared to similar curves for fixed blade propeller and Francis turbines, the efficiency at low loads being materially higher. Another feature of the Kaplan turbine is the overload capacity possible by adjustment of the blades, which is of particular value in times of reduced head during high river stages. It is expected that the efficiency of the Safe Harbor turbines will exceed 85 per cent over two-thirds of the load range, and to equal 90 per cent or better for the third quarter of the unit capacity.

Rehabilitation of Hydro Developments

The 57,000-hp. unit recently added to the Spier Falls plant on the Hudson River, New York, exemplifies two distinct tendencies in hydroelectric practise, illustrating in addition to the use of model testing as a design adjunct, the recognition of the value of an over-developed plant for supplying peak-load capacity and the benefit derived from a storage resource by a run-of-river development. At full load the wheel discharge is 7,000 cu. ft. per sec., making it the largest Francis-type runner to date in this respect as well as in physical dimensions. The minimum regulated flow of the Hudson River at Spier Falls is 3,000 sec.-ft., and 5,000 sec.-ft. for 50 per cent of the time. Both the turbine and generator approach record sizes in physical dimensions, the total weight of the rotating element being about 450 tons. The generator stator is 37 ft. in diameter, and the diameter of the scroll-case entrance of the turbine is 26 ft. The unit operates at a speed of 81.8 rev. per min. under a head of 81 ft. Tests of a model of the forebay and intake structures enabled the best forebay outline to be determined with regard to amount of necessary excavation balanced against the head loss in forebay and intakes. The tests revealed that the area of the intake gates could be economically reduced 20 per cent, and this was of special value because the water passages are so large that they gave rise to structural design difficulties. It is reported that the tests resulted in a saving equal to ten times the cost of the tests.

High Head Plants

The Waterville plant of the Carolina Power and Light Company on the Pigeon River in North Carolina has an unusually high operating head, 840 to 750 ft., for a hydro plant in the eastern part of this country. There are three 49,000-hp. reaction wheels in the plant, operating at 400 rev. per min. and these are of record note for their capacity at such a head. The six-mile tunnel from the reservoir created by the dam to the power house is unprecedented even in the notable high head installations on the Pacific Coast. The use of cast steel butterfly valves of 9 ft. diameter under a total head of 840 ft. located in the penstocks near the power house, has been reported quite successful, and is an advance in the size of such valves under high pressure. Johnson valves are also provided in the penstocks where they enter the plant.

The record for large capacity high head Francis wheels will shortly be established in the Diablo plant of the City of Seattle, where two turbines of 90,700-hp. capacity each, to operate under a head of 327 ft. are being installed. The turbines will have cast steel scroll cases and concrete elbow draft tubes.

The record head, however, for Francis wheels occurs in a European plant, the Bringhausen plant in Germany, where four 40,500-hp. horizontal-shaft Francis turbines are being installed to operate under a head of from 950 to 1,000 ft. This is a pumped storage development mentioned later.

Large Scale Hydro Developments

The Beauharnois development on the St. Lawrence River in Canada is notable for the ultimate capacity being planned when the entire flow of the river passes to the power house through the combined navigation and power canal connecting two of the lakes on the flow line of the river. The initial section of the plant will contain ten 50,000-hp. units, to operate under a head of 83 ft. The final capacity will be 2,000,000 horsepower. The construction of the canal between lakes St. Francis and St. Louis, which will be 15 miles in length with a width of 3,000 ft. and a depth of 27 ft. is outstanding because of its magnitude rather than any engineering difficulties.

Another plant that illustrates the scale of development possible on some of the rivers in Canada is the Chute-a-Caron plant on the Saguenay River where four 65,000-hp. units have been installed as the initial step of the future Shipshaw plant of 1,000,000 horsepower. The Chute-a-Caron dam will serve to divert the river for later construction of the Shipshaw plant, but because the head at Chute-a-Caron is only 151 ft. as contrasted to that of 205 ft. at the parallel site, the Chute-a-Caron plant will be operated in the future only during river flows sufficient to supply both plants. The difficulty of construction in the gorge of the Saguenay River is thus being solved by the step-by-step development at the two neighboring plant locations. The river was diverted in a unique manner for the construction of the Chute-a-Caron dam by toppling a concrete cofferdam 92 ft. long into the swiftly flowing current, which caused the flow to pass into an artificial channel previously prepared. The action of the concrete monolith weighing 11,500 tons was accurately predicted by means of model tests.

Storage Developments

The largest hydroelectric plant in New England has been recently completed at Fifteen Mile Falls on the upper reaches of the Connecticut River, in conjunction with the first 220-kv. transmission line in New England. The plant is designed for four 53,000-hp. units at 175-ft. head, and is the first development at two nearby sites which will eventually have a total combined rating of 300,000 horsepower. The completion of the second plant will create a reservoir for regulating the river flow not only for the plants at Fifteen Mile Falls, but also for the plants at Bellows Falls and Vernon, farther down the river. The 220-kv. line carries the output of the plant to a distributing point in the vicinity of Boston.

The Osage plant at Bagnell, Missouri, now approaching completion, will contain six 33,500-hp. units operating under an average head of 90 ft. Without storage this plant would not be feasible since the river flow varies from 324 to 110,000 cu. ft. per sec. with an average of 10,500 sec-ft. The dam will create a reservoir 95 sq. mi. in area having an impounded volume of 87 billion cu. ft., so that the flow of the river will be completely equalized with a draw-down of 30 feet. The average yearly energy available will be about 400 million kw-hr. The Osage plant is also a late example of the omission of a superstructure over the generator bay, the station crane having one gantry leg while the other end of the crane rests on top of the outer wall of the electrical bay which is placed over the penstocks between the dam bulkhead and the generator bay. Low metal housings are provided over the tops of the generators.

The Saluda storage development in South Carolina, described in the last report, was placed in operation last year and is notable for its reservoir capacity of 102 billion cu. ft.

Outdoor Type Plants

The omission of the generator room superstructure continues both for small plants of a single unit and for plants of large installed capacity. Generator designers are predicting that the flexibility of design now possible with fabricated construction, and the latitude permissible in the layout of auxiliary power and excitation systems, will lead to the arrangement of generators to conform to the design of the power house, and that the logical outcome may be the wider use of outdoor generator designs.

Pumped Storage Plants

No installations of pumped storage plants in America have followed the completion of the Rocky River plant in Connecticut, although the use of pumped storage continues popular in Europe where electric system peaks are of shorter duration than in this country. One illustration is the Bringhausen plant on the Weser River in Germany, now under construction, which will contain four combination pump and waterwheel units, each consisting of a 40,500-hp. Francis type horizontal turbine coupled directly to a 36,000-kva. generator, on the other side of which is a clutch for coupling to a 100,000-gal. per min. pump requiring 29,000 hp. for pumping. The plant is connected to an upper reservoir at an elevation 1,000 ft. higher by two penstocks 3,250 ft. in length. The water to be pumped to the reservoir amounts to 26,800,000 cu. ft., from which 500,000 kw-hr. will be generated. Power for pumping during off-peak hours is obtained from interconnected steam plants and other hydro plants on the system.

The horizontal coupling of a pump and a turbine with a generator and/or motor seems to be the preferred arrangement for pumping plants in Europe, and is in contrast to the Rocky River plant layout of pumping units with individual drive motors separate from the main turbine and generator, all of the equipment being of vertical type. The Rocky River pumps which are the largest high-head pumps in this country, have a volute discharge casing without diffusion vanes, and are of the single inlet type. On test the Rocky River pumps showed a maximum efficiency of 91.7 per cent; the efficiency expected by the designers of the German pumps is approximately 80 per cent.

Hydroelectric Generator Developments

There has been a widespread adoption during the past two years of fabricated steel plate construction of both stator and rotor of vertical waterwheel generators, in place of the use of castings formerly standard. Such generator construction of welded steel plate is lighter in weight, is considered to be more reliable mechanically, and is more adaptable to design arrangements. There has been an increased use of the umbrella, or overhung type of generator rotor, in which by means of downwardly curved rotor arms the centerline of the rotor rim or pole faces is brought below the horizontal centerline of the hub. By locating a combined guide and thrust bearing, sometimes of the spherical type, just below the rotor hub, a very material reduction in over-all generator height is secured. The use of rolled steel plates and fabricated construction for the stator has also facilitated the arrangement of ventilating ductwork in connection with the water tube air coolers that are now used very largely for generator cooling. Other advantages of fabricated plate construction are quicker manufacture and possibility of design for shipment without restriction by permissible weights or clearances.

Acknowledgments

This report has been compiled by a subcommittee, the members of which respectively prepared the several sections as follows:

F. A. Allner, Hydroelectric Topics; N. E. Funk, Major Influences in Current Design of Steam-Electric Plants, and Factors at Present Determining Maximum Size of Boilers and Turbines; F. H. Hollister, Rehabilitation of Existing Steam Plants, High-Voltage Generators, Switch Structures, Switching, and Control; H. W. Leitch, Reduction in Operating Costs of Steam-Electric Plants, and Technical Developments in Steam-Electric Plant Design.

The subcommittee wishes to express its appreciation of the helpful suggestions received from the main body of the Power Generation Committee.

Bibliography

The following list includes, of the vast literature produced on the subject of Power Generation in the last two years, only such salient articles and reports as describe or explain the newer developments and broader trends in the mechanical design of power plants. References to machinery details may be found in the comprehensive Engineering Index Service in the Engineering Societies Library, New York.

Power Transmission and Distribution

ANNUAL REPORT OF COMMITTEE ON POWER TRANSMISSION AND DISTRIBUTION[*]

THE Committee has continued with its work during the past year through a number of subcommittees organized as in preceding years. All of these subcommittees have been very active in studying the problems in their respective fields, and in promoting investigation work and the preparation of papers for presentation before the Institute. The reports of the work of the several subcommittees follow.

SUBCOMMITTEE ON DISTRIBUTION

One of the most interesting developments in connection with the distribution of electrical energy during the past year has been the practical application of the network principle to primary distribution. The economies and improvements to service which are made possible through the adoption of the low-voltage network have been so clearly demonstrated by the generally satisfactory performance of the many recent installations, that a wider application of the principle is not surprising.

At the present time there is being installed a 4-kv. primary network in Pittsburgh, Pa. This will serve a residential district of comparatively low-load density which was previously served by an overhead radial system.

The application of the network principle to 4-kv. service for such an area requires certain radical departures from the designs which have become fairly well established for distribution. Since underground construction in the areas of low-load density is not usually justifiable from an economic viewpoint, overhead construction must be used. The primary network deserves careful consideration from the standpoint of economy, reliability, and system planning in handling loads in areas not readily adaptable to low-voltage network distribution.

The past year has seen a continued application of vertical network distribution in large office buildings. This type of distribution has been used in a number of large cities including New York, Pittsburgh, and San Francisco. At the present time several features of design have not been settled. These features are being given consideration and it is expected that with the extended application of the vertical network principle a better understanding of them will result.

The question of secondary faults on low-voltage a-c. networks is still being discussed at length. There is a feeling among some engineers that the problem is not radically different from that encountered on the d-c. network. Others feel that short-circuit currents available are generally less and the condition is therefore more difficult. The use of buried cable has also been studied and tests made which will be reported in the near future.

SUBCOMMITTEE ON LIGHTNING AND INSULATORS

Past Year's Activities in Investigation Work

The activities in the field of lightning investigation during the past year have been carried on by means of:

1. Field investigation of natural lightning.
2. Field investigation with artificial lightning.
3. Collection of operating data on lightning performance of lines.
4. Theoretical analysis and coordination with the past lightning data.

In the field investigations, use was made of cathode-ray oscillographs, klydonographs (and surge recorders), surge indicators, lightning intensity recorders, direct-stroke recorders, and artificial lightning generators. This year the field investigation was extended to include a wood-pole line on which was recorded lightning voltages in the order of 5,000,000 volts.

By concentrated efforts in the field with the artificial lightning generator, a vast amount of knowledge has been gained on the effect of tower footing ground resistance, counterpoises, effect of normal voltage in sustaining a power arc in the presence of lightning flashover of a line, and particularly on the operation of the lightning arrester.

The behavior of traveling waves at the junction of cables with overhead lines was further studied by the use of the artificial lightning generator with particular attention to the application of lightning arresters.

Extensive use was made of the lightning (direct) stroke recorder and our knowledge in regard to the current in direct strokes amplified, and made more definite.

---

[*] COMMITTEE ON POWER TRANSMISSION AND DISTRIBUTION:

P. H. Chase, Chairman,
E. T. J. Brandon,
C. I. Burkholder,
A. B. Campbell,
C. V. Christie,
R. N. Conwell,
O. G. C. Dahl,
Harold C. Dean,
L. L. Elden,
H. S. Evans,
R. D. Evans,
F. M. Farmer,
J. H. Foote,
K. A. Hawley,
L. F. Hickernell,
J. P. Jollyman,
A. H. Lawton,
L. L. Perry,
T. F. Peterson,
D. W. Roper,
A. E. Silver,
D. M. Simmons,
C. T. Sinclair,
L. G. Smith,
Philip Sporn,
W. K. Vanderpoel,
C. F. Wagner,
H. S. Warren,
T. A. Worcester.

The cathode-ray oscillograph application was modified to trace the history of a natural lightning wave over a period of some 2,000 microseconds, in addition to recording the initial characteristics of the waves.

Surge indicators were used for the first time, although mentioned in last year's report. These definitely established the fact that a lightning flashover of a transmission line can take place without sufficient follow-up current flowing to trip out the line.

The past year has brought out some intensive study of a theoretical nature on the lightning problem dealing with the mechanism of the lightning stroke and the subsequent surges which may appear on a transmission line. Both the direct stroke and induced stroke have been analyzed and the conclusion pointed out that only direct strokes appear to have consequential effect on the highly insulated lines, while medium and lower insulated lines will be affected in an increasing order by induced strokes.

Results of Last Year's Work

It is impossible here to point out in detail all the results of last year's investigation. There are, however, some outstanding accomplishments, among which the following are cited.

1. The effectiveness of ground wires in reducing lightning voltages and line outages has been further demonstrated.
2. The value of low tower footing resistance in lessening the effects of lightning voltages has been shown.
3. Currents in the lightning stroke in the order of from 50,000 amperes and upwards have been indicated.
4. Counterpoises at a tower footing, even although of comparatively short length are beneficial in reducing the lightning voltage to which a line may be subjected.
5. Lightning sparkover of a line can take place without power follow current.
6. Lightning voltages of both direct and induced stroke origin appear to be present on transmission lines. It is not known in what normal insulation and voltage range the induced voltage ceases to be a factor in line flashover.

Insulation Coordination

In order to coordinate insulation on a lightning basis, its lightning characteristics must be known. Whether these are secured on a single impulse wave or voltage time lag basis, a standard test method must be agreed upon by all who supply this type of data. The Committee has this matter well in hand at the present time, with the probability that an agreement will soon be reached by all actively engaged in this work whereby a group of two or more preferred waves will be used for securing this type of data.

Insulator Flashover Values.

It has been known for some time past that discrepancies have existed in 60-cycle flashover values assigned to insulators of practically the same physical dimensions. The cause for these different flashover values has been traced to a variation in humidity conditions at the time and place of test. A great deal of experimental work has been done on this problem, and it is expected the information obtained will soon be made public through a group of papers before the Institute.

SUBCOMMITTEE ON INTERCONNECTION AND STABILITY FACTORS

In order to coordinate the work of the Power Generation Committee, the Protective Devices Committee and the Power Transmission and Distribution Committee in the field of interconnection and system stability, there has been formed a Joint Interconnection Subcommittee. This Subcommittee was organized during the year and has arranged several sessions of interest in the field of transmission and distribution. These include the session on System Grounding at the Pittsburgh Meeting in March 1931 and the session on System Interconnection for the Summer Convention of 1931. In addition, plans are under way for a symposium at the Winter Convention of 1932 on the subject of Machine Characteristics and System Stability. In last year's report mention was made of the organization of a Subject Committee on Definitions of Terms Used in Stability Investigations. The work of this Subject Committee is now substantially complete and it is planned to present it as a paper at the Winter Convention in 1932.

SUBCOMMITTEE ON CABLE DEVELOPMENTS

This year has witnessed the continued practically universal use of shielded cable (type H) for all three-conductor high-voltage cables. Other tendencies are the increased use of oil-filled cables, the use of super-calendered paper, a great increase in the use of non-metallic armored cables for direct burial in the ground for low-voltage work, and the use of steel-wire armored, non-leaded cables for submarine service and for vertical distribution cables in high buildings.

The Following Cable Installations May Be Noted:

1. A second circuit, 175,000 kva. (winter rating), of single-conductor 132-kv. oil-filled cable about 6 miles long by Commonwealth Edison Co. in the same conduit bank as their first circuit. The new circuit has 1,100,000 cir. mils conductors as compared with the 600,000 cir. mils previously used. The larger conductor size is made commercially feasible by insulating sleeves and grounding devices to eliminate sheath losses. Due to the many improvements in accessories and technique, the net result was that the investment cost per kva. of capacity is less than one-half the cost of the first line.

2. Two lines of single-conductor 600,000-cir. mil 132-kv. cables each three-quarters of a mile long installed by the Commonwealth Edison Co. one (90,000 kva. rating) similar to the cable of paragraph 1 above, and the other (95,000 kva. rating) with novel features of oil channels cut in the interior of the lead sheath as well as an oil channel in the conductor, a simple and small stop-joint, making it possible to have every joint a stop-joint, which joint is practically a factory-made and factory-tested joint.

3. The Deepwater installation of the United Gas Improvement Co. across the Delaware River consisting of two 60,000-kva. circuits (and two spare cables) of single-conductor 750,000-cir. mil 75-kv. solid type cable manufactured and installed in single lengths each about 4,000 ft. long. These are the first 75-kv. submarine cables and longest lengths of power cable ever manufactured.

4. Two circuits rated at 55,000 kva. each of single-conductor 750,000-cir. mil 75-kv. solid type submarine cable of the Union Electric Light and Power Co. of St. Louis across the Mississippi. The cables were made and installed in single lengths of about 2,800 ft. each.

5. An installation of five three-conductor 48,000-kva. 66-kv. oil-filled cables by the Union Gas and Electric Co. of Cincinnati. This is the first three-conductor 66-kv. oil-filled cable, and is buried direct in the ground. The conductor size is 500,000 cir. mils sector, insulated with 0.40 in. impregnated paper and shielded. The cables are made in single lengths 1,300 ft. long, thus avoiding joints, and are steel-tape armored cables buried directly in the ground.

6. Three commercial installations have been made during the year of three-conductor 33-kv. to 35-kv. oil-filled cable, although the amounts were rather limited. These installations were made by the city of Los Angeles, the Staten Island Edison Co., and the Syracuse Lighting Co. All three installations were made with three-conductor type H cable with oil channels in the filler spaces. A novel feature was the three-conductor positive stop-joint by the city of Los Angeles, and also the fact that a large installation of cable with oil channels in the filler spaces including a more viscous oil was installed by this company, who after installation replaced the oil in the channels by oil of the type used in oil-filled cables.

7. An experimental installation of single-conductor 132-kv. oil-filled cable by the Commonwealth Edison Co. of Chicago in cooperation with two manufacturers, each of whom supplied 1,000 ft. of 450,000-cir. mil or 500,000-cir. mil cable insulated with 0.40 in. paper and 1,000 ft. with 0.50 in. paper. The purpose of this experiment is to study the limiting stresses and temperatures in oil-filled cable for present and future voltages.

8. An experimental installation of single-conductor 132-kv. cable by the Public Service Electric and Gas Co. as a continuation of their 1927 experiment studying the possibility of "solid type" insulation for 132-kv. service. The installation consists of three cables each of 500,000 cir. mils and 1,000 ft. long, two supplied by one manufacturer and one by another. Each manufacturer supplied a length of solid-type cable. The third cable is of an intermediate or hybrid type, using oil intermediate in viscosity between that of an oil-filled cable and of the usual type of cable, thus greatly facilitating installation methods while sharing in part the operating advantages of an oil-filled cable.

The Subcommittee on Conduit and Manhole Temperature of the N. E. L. A. Underground Systems Committee has standardized on conditions and constants for calculating current-carrying capacity. This standardization has made it possible to calculate current-carrying capacities of cables covering a large range of sizes and conditions. These tables of carrying capacities will be published by the Underground Systems Committee, and should prove of great value to the industry.

SUBCOMMITTEE ON STEEL TRANSMISSION TOWERS AND CONDUCTORS

The Subcommittee on Steel Transmission Towers and Conductors was organized to assist in the standardization of steel transmission towers and conductors by clarifying the problems associated with their design and application, by papers prepared by recognized authorities on these subjects and presented before the Institute.

The work of the Subcommittee has been divided into three groups, each of which is responsible for one of the following subjects:

I—Towers.

II—Clearances and Electrical Characteristics.

III—Conductors.

During the past year, four meetings of the Subcommittee have been held, together with some additional meetings of groups within the Subcommittee.

An addition to the clause of the N. E. L. A. specifications on uplift of tower foundations and a recommendation for a straight line compression formula for the N. E. L. A. specifications is in course of preparation. Consideration is being given to elimination of the term "factor of safety" by substituting therefore "per cent overload." Contact is being maintained with the A. S. T. M. on its investigation of embrittlement of hot dipped, galvanized steel.

It is proposed to recommend that the 60-cycle flashover be the basis for clearance of the tower under winter or heavy loading conditions and that lightning flashover be the limit for summer or light loading conditions. The width of the right-of-way is to be limited by similar conditions.

Intensive study is being given to the vibration of conductors. Efforts are being directed principally to the coordination of experimental work being done by widely separated investigators, including California, Texas, Illinois, Michigan, Ontario, England, and Australia. A bibliography is being established as an adjunct to this work.

The present membership of this committee, including the chairman, is now twenty, with five men in Group I, six men in Group II and eight men in Group III.

It is felt that the work of this subcommittee is now progressing smoothly and during the next year, concrete results can be shown as the result of its activities.

CONCLUSION

For the sake of brevity, this year's report excludes the bibliographies of papers which appeared in last year's report. It is planned to include such bibliographies in the Annual Report at appropriate intervals, rather than every year.

In conclusion, it is desired to stress the conscientious and enthusiastic work of the chairmen and members of the subcommittees to whose liberal contributions of time the progress made is due.

Transportation

ANNUAL REPORT OF THE COMMITTEE ON TRANSPORTATION*

YOUR Committee on Transportation submits a brief review of the recent developments of importance in the application of electricity to transportation.

STEAM RAILROAD ELECTRIFICATION

Pennsylvania Railroad

The Pennsylvania Railroad has been actively continuing its electrification program. On June 29, 1930 electric operation was inaugurated between Philadelphia and Trenton, N. J., a distance of about thirty miles. On July 20th, electric operation was started between Philadelphia and Norristown, Pa., on the Schuylkill Division, seventeen miles. Fifty-nine multiple unit cars have been recently acquired. This installation completes the suburban electrification about Philadelphia. Distribution of power is at 11,000 volts, 25-cycle, single-phase. The equipment for suburban service is at present all motor cars, with multiple unit control.

The new suburban terminal at Broad Street was opened on September 28th. This is of necessity, entirely electrically operated, for the tracks are, like those of the passenger terminal at New York, under cover. The new suburban station at Thirtieth Street on the west bank of the Schuylkill River was also placed in service at this time. This will ultimately be an integral part of the Pennsylvania Terminal at West Philadelphia now under construction.

The Pennsylvania Railroad now has in electrified operation about Philadelphia, 132 miles of route and 437 miles of track; 345 multiple unit cars are in service.

Work is actively progressing in the New York Terminal zone preparatory to changing from the 600-volt third rail to 11,000-volt, single-phase trolley wire between Sunnyside Yard and Manhattan Transfer. This installation, which will among other things allow New Haven locomotives to enter the Manhattan Terminal, should be completed during the present year.

Construction is progressing between New Brunswick and Manhattan Transfer and will shortly be started between New Brunswick and Trenton, and between Wilmington and Washington.

Four types of locomotives are being developed for the complete electrification. Two passenger types, one freight and one yard switching. The light passenger type (designated as 0-1) is of 2-B-2 arrangement, and two of these units will be used on the heavy passenger trains. The heavy passenger type (P-5) is of the 2-C-2 arrangement. The freight type (L-6) is of the 1-D-1 arrangement. The passenger locomotives will use twin motors rated at 500 hp. per armature, or 1,000 hp. per axle. The freight locomotive will be equipped with four motors of single armature type, and will thus have a rated capacity of about 2,000 hp.

Long Island Railroad

The multiple unit suburban service of the Long Island portion of the Pennsylvania Railroad, operated by third rail distribution, is rapidly growing. Eighty-five multiple unit cars now being added to the equipment, bring the total number of cars to 825. To provide power for the increasing load, the Floral Park substation is being remodeled and will be equipped with two rectifiers of 3,000-kw. capacity. Four new substations—Hempstead, Manhasset, Rockaway Park, and Goose Creek—are being built, in addition to four planned for installation next year. Each of the new substations will contain one 3,000-kw. mercury arc rectifier, except at Goose Creek where portable synchronous converter equipment will be installed. The rectifiers will be adapted for 60 or 25 cycle operation, an external reactance being added for the lower frequency.

---

*COMMITTEE ON TRANSPORTATION:

R. P. Winton,
G. I. Wright.

Delaware, Lackawanna & Western Railroad

The suburban electrification of the D. L. & W. R. R. was inaugurated between Hoboken and Montclair, N. J. on September 3, 1930, the service to South Orange, N. J. September 22, 1930 and that to Morristown, N. J. December 18th. The present electric installation was completed with the electric operation in January 1931 to Gladstone and Dover, N. J. This electric operation comprises about sixty-eight route miles and one hundred and fifty-eight miles of track; and includes 282 multiple unit cars. These cars operate in pairs, the units consisting of one motor car and one trailer each. Five substations, each containing mercury arc rectifiers, furnish the distribution power at 3,000 volts direct current. Two electric three-power locomotives (oil, storage battery, and trolley operated) have been acquired and are used for switching and transfer service between Jersey City and Secaucus freight yards. The D. L. & W. is the first heavy traction service in this country to utilize 3,000-volt direct current on motor cars, and the first to install exclusively mercury arc rectifiers.

New York Central Railroad

The Cleveland Union Terminal electric operation was inaugurated June 28, 1930. This project comprises 17 miles of route and about 60 miles of track, between Collinwood and Linndale, Ohio, and employs twenty-two locomotives. These locomotives are 2-C + C-2, weighing about 204 tons, of which 150 tons is on drivers. They are designed for a maximum speed of 70 mi. per hr. The locomotives are used interchangeably for switching or road service. Train heating boilers, oil-fired, are provided on the locomotives. The power distribution is by means of 3,000-volt direct current, using a catenary system. This is supplied from two substations, one 3.5 miles west, and the other 7.2 miles east, of the Union Station; each equipped with motor-generators, remotely controlled from the terminal building by a supervisory system of the synchronous selective type. The installed capacity is 9,000 kw and 6,000 kw. respectively.

The New York City electrification of the New York Central is progressing. The "West Side" tracks will be electrified by the middle of the current year as far south as Seventy-second Street, the tracks north of that point being on a viaduct, or on private right-of-way. Forty-two freight locomotives have been purchased for this service. Distribution of power is by direct current at 650 volts using a third rail. South of Seventy-second Street the tracks are on city streets, and the operation will be accomplished by three-power (oil-electric-storage battery) locomotives, of which the railroad has purchased thirty-five.

Reading Railroad

The electrification of the Reading Railroad at Philadelphia is progressing, and operation should be started about the middle of the current year. This project includes about 69 route miles and 161 miles of track; seventy multiple unit cars will be operated initially. The distribution system is at 11,000 volts, single-phase, 25 cycles.

Great Northern Railway

The Great Northern Railway has placed in service four new motor-generator locomotives with axle arrangement 1-C + C-1, essentially similar to those of that type already in operation. Each locomotive weighs 263 tons, of which 210 tons is on drivers. The distribution of power is at 11,000 volts, 25 cycles, single-phase.

Illinois Central

The Illinois Central Railroad placed in service in 1930, four 100-ton straight-electric locomotives for switching service, and also five 600-hp. oil-electric locomotives of the Diesel type. The motive power now in suburban service consists of 280 multiple unit cars, 140 of which are motor cars and 140 are trailers. In the freight switching service, there are now four straight-electric locomotives and six 600-hp. oil-electric. The power distribution is 1,500 volts, direct current. About 154 track miles are electrified.

New York, New Haven and Hartford Railroad

The final extension of the New York, Westchester and Boston Railway to Port Chester, N. Y. was completed late in 1929. The New York, Westchester and Boston—an integral part of the New Haven electric operation, now operates from Harlem River to Mount Vernon, N. Y., with branches to White Plains, N. Y. and to Port Chester, N. Y. The total New Haven a-c. electrified mileage is now about 577 track miles, over approximately 116 miles of route. The road operated, as of the end of 1930, 141 electric locomotives and 267 multiple-unit cars. The New Haven last year placed in service nine multiple-unit cars. During the current year there will be added to the equipment, ten 200-ton passenger locomotives and 33 multiple-unit cars. The power distribution of the New Haven is at 11,000 volts single-phase, 25 cycles, but the passenger motive power is designed to take power also from the New York Central third rail at 650 volts, direct current.

Substations for Electrified Railroads

The conversion of power for distribution on the Delaware, Lackawanna and Western electrification is, as previously noted, entirely by means of mercury arc rectifiers. This installation consists of 18 units in 5 substations with a total capacity of 40,000 kw. The rectifiers are also provided with a means of compounding, so that voltage can be maintained over a fairly wide load range at substations. Reference is made to the report of the Technical Committee on Automatic Stations covering this feature. Four of the substations are manually operated but are provided with many of the usual automatic protective features. One substation is completely automatic. Remote and supervisory control are provided for the automatic substation and the tie stations.

In its electrification the Pennsylvania Railroad has continued with the 11,000-volt distribution system now in use on other parts of its system involving step-down transformer substations installed at intervals of 7 to 8 miles. The Reading electrification consists of the three-wire distribution system with 11,000 volts on the trolley and a feeder of 33,000 volts. Auto transformer stations are used at intervals, to transfer energy from the 33,000-volt feeder to the 11,000-volt trolley. Some of the substations of the Pennsylvania Railroad electrification are remotely controlled from adjacent signal towers, and those of the Reading are controlled by supervisory control so that the power director indirectly or directly has control of all circuit breakers within his jurisdiction.

The Cleveland Union Terminal Substations contain two and three 3,000-kw. motor-generator sets respectively, with complete automatic control. A synchronous selective supervisory control system with remote telemetering provides the dispatcher, located in the Terminal Building, with complete supervision and indication of the substation, feeders and tie station.

High-speed air circuit breakers have been employed in all substations of the d-c. systems mentioned above, and the Pennsylvania Railroad and Reading Railroad a-c. systems have employed high-speed a-c. breakers of the air and oil type. Reference is made to the report of the Committee on Protective Devices for data regarding the various types of high-speed circuit breakers available for a-c. and d-c. service.

Electric Locomotives

A novel development in the field of a-c. locomotive design has occurred abroad. In this design the low-voltage terminals of the transformer are permanently brought out, and all voltage control for the motors is by means of an oil-immersed tap changer and air switches from the high-voltage windings. The arrangement is a development of the growing use of the scheme of "tap-changing under load" and if it is found to be practicable under service conditions, should materially simplify the design of a-c locomotives.

A novel development in electric locomotive design has been accomplished in the new locomotive of the Illinois Central Railroad. This compensates the tendency of reduced weight upon the forward drivers at high drawbar loads, especially at starting, on account of the moment of the drawbar pull and rail reaction. The arrangement consists of shunts for weakening the field of the leading motor of each truck, which reduces the tractive effort of the leading motor and increases that of the rear, in proportion to the field strengths of the two motors. The forward drivers thus show less tendency to slip and the drawbar capacity is therefore increased.

There has been a number of notable improvements recently in the design and construction of the single-phase motor which have materially decreased its weight per horsepower and have improved efficiency and power factor. Attention is called to the report of the Committee on Electrical Machinery for descriptions of these developments.

Oil-Electric Locomotives

In addition to 35 oil-electric-storage battery locomotives acquired by the New York Central Railroad for the "West Side" operation in New York City, seven similar units have been placed in service in Chicago, and as above stated, two on the Delaware, Lackawanna & Western Railroad. The Canadian National last year acquired a Diesel locomotive, as have various industrial concerns.

A novel arrangement of Diesel locomotives has been developed, wherein the engineer's driving position is raised to a sort of mezzanine floor, so the engineer may look over the top of the train he is moving. In this design, controllers, air brake handles, etc., are provided at both sides of the cab so the driver may move from side to side as desired to observe signals from the switching crew.

Rail Cars

Fifty-six rail cars of gasoline and oil electric design were produced in this country during the past year. As an indication of the increasing use of this type of equipment in heavier service, the average power of these cars was about 450 hp. as compared with about 350 hp. the average in 1928.

MARINE TRANSPORTATION

A number of turbo-electric and Diesel-electric vessels of various types was produced in 1930. The *S.S. President Hoover* is the largest electrically driven liner produced thus far. The propelling equipment consists of two 14,000 hp. turbines with three-phase 10,100-kw. generators, and two 13,250-hp. synchronous induction motors. Auxiliary electric apparatus on steam and Diesel propelled craft has developed in a number of different directions, replacing steam auxiliaries. Attention is called to the report of the Technical Committee on Application of Electricity to Marine work.

AVIATION

A number of electrical devices has added to the art of aviation during the past year. Among these is the "turn compensator," an electrically driven device to correct the error experienced in all types of "earth inductor" compasses when the direction of the ship is suddenly changed. This device may also be used as a "turn indicator" to show quickly and with reasonable accuracy the angular change in direction.

Recently developed engine-performance indicators, electrically operated, showing oil-pressure, oil-temperature, speed, etc., are of value especially on multiple-engine ships, by permitting remote indication.

In the field of illumination for aviation, wing-lights set into the leading edge of plane wings increase efficiency by reducing non-productive air resistance. Airways are being illuminated by increasingly powerful and efficient beacons. The illumination of landing fields by means of flood lights and marking lights is keeping pace with other developments.

RAILROAD SIGNALING

Centralized traffic control by means of coding systems is rapidly being extended on railroads. This enables a dispatcher or tower operator to remotely control switches and signals over a large territory and thus direct trains quickly and effectively without the necessity of train orders.

URBAN TRANSPORTATION

The chief developments in urban transportation are efforts to obtain faster car acceleration, higher speeds, and better braking, to compete with increasingly difficult traffic conditions. The increased use of double-reduction and worm gears has made the operation of higher speed motors practicable with marked decrease in weight (especially in unsprung weight). Lower floors, with greater speed in loading and unloading, are features of some of the new drives.

The modern trolley bus is being used for many services where street cars or gasoline buses were applied previously. Economy of operation and low investment cost insure a widespread use of trolley buses, especially where it is possible to utilize existing power plant, substation, and power distribution facilities. In Chicago, for instance, over fifty-seven miles of line have been equipped for trolley bus operation, and seventy-five buses are in use.

The gas-electric coach, which has hitherto shown its chief advantages in congested urban traffic where frequent and rapid acceleration is necessary, is invading the interurban field.

Attention is called to the expansion of the subway mileage in Philadelphia, New York, and Brooklyn. Plans for a subway in Chicago have been approved.

RAIL FISSURE DETECTOR

The Sperry device for detecting fissures in track rails has been operated intensively throughout the country with valuable results. Continued use of this device should materially reduce rail failures.

WELDING

Electric welding is increasingly used not only in railroad shops (as in other industries), but for building up rails and "special work" at frogs, crossings, etc. Rail bonds for traction and signal purposes are in many instances welded to the head of the rails.

VERTICAL TRANSPORTATION

The ever increasing height of buildings necessitates constantly increasing efficiency and speed of elevators. Speeds of 900 ft. per min. are now operated. A recent development to increase space efficiency in high buildings, is the operation of two or more elevators in a single shaft, so synchronized that one elevator may be started and run as "express" for a certain number of floors before the car next below it starts. Needless to say the operation is interlocked by means of limit switches and kindred devices to prevent the cars from coming together.

GENERAL

Attention is called to the development of various types of apparatus which apply to transportation as well as to other forms of utilization of electricity as described in various technical committee reports. Included in this category are turbo-generators and other power plant facilities, motors, circuit breakers, insulators, transformers, lightning arresters, cables, relays, substations, etc. Many of these types of apparatus are applicable to transportation, only by accomplishing some more or less important modifications, and the attention of various technical committees has been called to special modifications of this kind.

Attention is called to the work which is being carried on under the auspices of the American Standards Association on Definitions of Electrical Terms (C-42) for which the A. I. E. E. is sponsor. To Subcommittee No. 6 is assigned the field of "Horizontal Transportation." It is hoped that when this very important subject is complete, and published, general use will be made of the definitions and that some confusion which now exists will thus be avoided.

Protective Devices

ANNUAL REPORT OF COMMITTEE ON PROTECTIVE DEVICES*

THE work of the Committee on Protective Devices during the past year was accomplished largely through subcommittees, which are listed below with their chairmen:

Relays, W. W. Edson; Oil Circuit Breakers, Switches and Fuses, L. F. Hickernell; Lightning Arresters, H. K. Sels; Fault Current Limiting Devices, H. B. Wood; Joint Interconnection Subcommittee,† F. C. Hanker.

The activities of the Protective Devices Committee may be divided into the following three classes:

1. Preparation of standards
2. Review of research and development
3. Fostering the preparation and presentation of papers.

GENERAL

During the year the work of the committee in cooperation with the National Electric Light Association in the preparation of a supplement to the Relay Handbook was completed.

Revised standards for lightning arresters have been prepared and issued in report form by the Standards Committee.

Progress has been made in the preparation of standards for fuses and revised standards for disconnecting, horn gap and knife switches. It was hoped that the standard for fuses could be sent to the Standards Committee this year, but due to difficulties in obtaining complete agreement as to the subject matter of this standard there has been some delay. These standards should be forwarded to the Standards Committee in the latter part of 1931.

The committee has maintained close contact with research and development relating particularly to lightning protection, high-speed oil circuit breakers, and stability of operation, which greatly facilitated its work in fostering the preparation of suitable papers relating to these subjects.

The work of the committee during the past year has emphasized more than ever the following points. First, the desirability of planning the presentation of papers sufficiently in advance so that they may be grouped for presentation in the most suitable manner. Second, the necessity, if maximum advantage is to be realized from Institute sessions, of having papers available for reading sufficient time in advance of meetings to permit of well considered discussion. The importance of this latter point is so great that every effort should be made to see that it is carried out effectively.

On account of the fact that in a number of cases other technical committees of the Institute have a very definite interest in the application or use of devices coming under the jurisdiction of the Protective Devices Committee, very close coordination of activities is required. This is particularly true in matters relating to interconnection and stability of operation handled at the present time by the joint subcommittee having representatives from the Power Generation and Power Transmission and Distribution Committees, in addition to the Protective Devices Committee. It may be that there will be sufficient important matters which affect a number of committees to warrant selecting some method of handling them that will permit of direct effective action without the complication and delays that are bound to happen in coordinating work with several large committees.

RELAYS

Report of Subcommittee

Further development of high-voltage transmission and interconnection with rather severe requirements as to stability and continuity of service, have focused attention on the necessity of rapid clearing with extreme precision, and the development of the art of relay protection has advanced as a consequence. Relays have been developed including directional, balanced, and differential relays capable of operating in one-sixtieth of a second.

These are being tried out in service and their operation is being watched with much interest. Apparently, additional work should be done to simplify these relays and their mechanical construction details, so as to insure among other things high-speed operation under all conditions, and to prevent shifting of the balance point. Also, further development will apparently have to be gone ahead with to eliminate certain difficulties in the application of these relays to short line sections or to ground protection.

---

*COMMITTEE ON PROTECTIVE DEVICES:

Raymond Bailey, Chairman,
J. E. Allen,
A. C. Cummins,
H. W. Drake,
W. S. Edsall,
W. W. Edson,
L. E. Frost,
E. B. George,
Herman Halperin,
F. C. Hanker,
E. A. Hester,
L. F. Hickernell,
Dr. M. G. Lloyd,
J. P. McKearin,
H. A. McLaughlin,
A. M. Rossman,
A. H. Schirmer,
H. K. Sels,
H. P. Sleeper,
E. R. Stauffacher,
H. R. Summerhayes,
E. M. Wood,
H. B. Wood.

†This is a joint subcommittee of the committee on Power Generation, Power Transmission and Distribution and the Protective Devices Committee.

The most important work of the subcommittee for the year is the completion of the revised edition of the Relay Handbook, in cooperation with the corresponding committee of the N. E. L. A.

The following papers, prepared under the auspices of this subcommittee, have been presented before the Institute:

Relay Developments on Southern California Edison System, E. R. Stauffacher, Southern California Edison Company.

Operating Experience with Reactance Type Distance Relays, E. E. George, the Tennessee Electric Power Company.

Protection of Three-Winding Power Transformers, R. E. Cordray, General Electric Company.

Fundamental Basis of Distance Relaying, W. A. Lewis, Westinghouse Elec. & Mfg. Company.

OIL CIRCUIT BREAKERS, SWITCHES, AND FUSES

Report of Subcommittee

A prominent feature of oil circuit breaker development is the number of large installations of metal-clad switchgear. Among these may be mentioned the installation of 33-kv. oil-filled gear on the system of the Public Service Company of Northern Illinois, the 13-kv. gum-filled gear at the Leaside Substation of the Hydro-Electric Power Commission, and air-filled gear on the system of the Jersey Central Power & Light Company.

Since last year's development of the deion circuit breaker, further results have followed the discovery of this method of arc extinction. With the addition of deion grids, ordinary oil circuit breakers have opened 3,500 amperes at 110,000 volts with 1.5 cycles of arcing; and 3,000 amperes at 200,000 volts with 3.5 cycles of arcing or less. Decreased arcing assures more satisfactory breaker performance, less deterioration of oil and contacts and lower maintenance. The stability of the whole power system is improved, since short circuits are more likely to be cleared before they can affect synchronous machines.

The deion oil-less breaker in the meanwhile has been developed for a greater range of ratings. At one extreme is a one million kva. 23 kv. circuit breaker which has undergone interrupting capacity tests including some shots as high as 800,000 kva. (It will be recalled that among last year's achievements were reported successful interruptions of short circuits in the order of 60,000 kva.) On the other extreme is the breaker (using 2.5-inch plates) which repeatedly interrupted 10,000 amperes at 600 volts alternating current. This small deion breaker shows great promise in a wide field of the moderate and smaller powers; such, perhaps, as industrial service.

Efforts to improve rating standards for oil circuit breakers continue.

Announcements by the manufacturers indicate healthy activity in the development of new forms of circuit interrupters, such as the oil-blast oil-circuit breakers, multiple break and others.

The following papers, prepared under the auspices of this subcommittee, have been presented before the Institute:

The Mechanical Performance of Oil Circuit Breakers, A. C. Schwager, Pacific Electric Mfg. Co.

Outdoor Switching Equipment at Northwest Station, W. F. Sims and C. G. Axell, Commonwealth Edison Co.

Magnitudes and Rates of Rise of Circuit Breaker Recovery Voltages, R. H. Park and W. F. Skeats, General Electric Co.

Trend in Development of Modern Circuit Interrupters, J. B. MacNeill, Westinghouse Elec. & Mfg. Co.

Oil Circuit Breaker Tests—Philo 1930; Aims, Set-Up and Results from a System and Operating Point of View, Philip Sporn and H. P. St. Clair, American Gas & Elec. Co.

The Oil-Blast Circuit Breaker, D. C. Prince and W. F. Skeats, General Electric Co.

Field Tests on Standard and Oil-Blast Explosion Chamber Oil Circuit Breakers, R. M. Spurck and H. E. Strang, General Electric Company.

LIGHTNING ARRESTERS

Report of Subcommittee

The Subcommittee is advised that studies of lightning and the effects of lightning were continued throughout the year by means of field investigations on transmission systems in several widely separated localities. The knowledge of the character and behavior of high-voltage surges originating from lightning on transmission lines was extended by the use of cathode-ray oscillographs at field stations located in Arkansas, Illinois, Michigan, New Jersey, Ohio, Pennsylvania, and West Virginia. In two cases, Michigan and New Jersey, the behavior of waves on transmission lines was studied in detail by the use of both portable cathode-ray oscillographs and impulse generators. Practically a continuous investigation was maintained also of the performance of lightning arresters and many other associated phases of the lightning protection problem. About 3,000 oscillograms were taken which have already proved valuable in the study of problems related to lightning protection.

Better coordination of records in the 1930 lightning investigations has indicated the growing importance of direct strokes. Records obtained on high-voltage lines tend to confirm the thought that overvoltage due to direct strokes are more important than those due to the induced effect from lightning strokes primarily on account of their greater magnitude.

Impulse tests made in the field tend to confirm the conclusion that best protection with lightning arresters is obtained when the arrester is located close to the equipment to be protected and the leads as short as possible with low ground resistance. If the arrester cannot be located close to the equipment and at the same time retain short leads, keeping the leads short appears to be the more important. Also, the arrester and equipment should be connected to the same ground but if this is not convenient, more attention must be given to the arrester ground to be sure that its resistance is as low as possible.

The highest voltage lightning arresters ever built were recently installed by the Hydro-Electric Power Commission of Ontario. Under emergency conditions of generator overspeed and abnormal line voltage, they will not be damaged by voltages as high as 268,400 volts. Normally, four of the twenty-two arrester units in each phase leg are short circuited by a high speed switch which opens automatically in less than half a second when waterwheel overspeed and overvoltage occurs. This is also the largest arrester installation for voltages over 200,000. One three-phase arrester is installed for the protection of each of four banks of transformers.

The commercial development of the porous block autovalve arrester has made available a new arrester which is considerably smaller and has much better performance characteristics than the earlier autovalve. The arrester is constructed in fewer porcelain-cased units with a totally enclosed gap structure which in the lower voltage sizes results in the complete arrester being housed in a single casing or two casings with gaps and elements separate. The protective action of the arrester is similar to the old one but it has practically no time lag in its operation and a low ratio of discharge voltage to normal voltage. A small and compact form of line arrester has been developed which can be applied to prevent the flashover of insulator strings. A number of installations of these line arresters has been under observation for the past two years in order to gather data on the effectiveness of such protection for transmission line insulators.

With the commercial development of thyrite, a new form of lightning arrester became available. The arrester is constructed in the form of self-contained units, it only being necessary for any application to mount an appropriate number of units one upon another. A gap structure has been provided in each unit so constructed that substantially no time lag occurs in the operation of the gap. This arrangement, coupled with the characteristics of the material, insures an arrester which has practically no time lag in its operation. A number of installations of these arresters has been made, the highest voltage arrester in service being of 230 kv. rating. Another form of thyrite arrester was developed which is incorporated in a string of suspension insulators and used to prevent the flashover of the insulator string for all but the most severe conditions.

A new protective device operating on a deion principle in a small bore tube for use in the prevention of insulator flashover by lightning has been developed in certain voltage ratings.

The revision of the proposed Standards for Lightning Arresters for alternating-current power circuits was completed and accepted by the Committee on Protective Devices for printing in report form. The subcommittee hopes that there will be widespread use of these standards in order that they may be put in final shape for adoption by the Institute. It is expected that development in the art of protection from lightning will probably make it necessary to revise these standards from time to time as additional technical information becomes available.

The work of the subcommittee indicates that the following matters should receive considerable attention in the future: (1) the determination of more representative test surges, (2) the development of tests to determine operating condition of arresters in service, (3) investigation of present operating practise on transmission and distribution systems relative to arrester installation, operation and performance as affecting suitable standards, and (4) the coordination of line and station type arrester application in the field with the activities of other committees interested in the grading of system insulation.

The following papers, prepared under the auspices of this subcommittee, have been presented before the Institute:

An Experimental Lightning Protector for Insulators, J. J. Torok, Westinghouse Elec. & Mfg. Co.

Field Tests on Thyrite Lightning Arresters Using Artificial Lightning of 1,500,000 Volts, K. B. McEachron and E. J. Wade, General Electric Company.

FAULT CURRENT LIMITING DEVICES

Report of Subcommittee

The reactor installations made during the year are characterized by high electrical ratings and greater physical size, particularly in bus-sectionalizing applications which seem to be on the increase.

Among the largest ever built in physical size is an application of 4,000-kva., 161-kv. bus sectionalizing reactors giving 10 per cent reactive drop when 120,000 kva. is transferred across the reactor.

Another outstanding installation from the standpoint of physical size consists of three 5,400-kva. oil-immersed reactors on the 110-kv. system of the Pacific Gas & Electric Co.

Noteworthy from the standpoint of electrical rating are eighteen bus-sectionalizing reactors rated 7,340 kva. giving a 16½ per cent reactive drop in a 133,000-kva., 27,600-volt circuit now on order.

Current-limiting reactors of the dry type installed in metal housings and rated 833 kva., 693 volts, 1,200 amperes, 60 cycles, were used to sectionalize a 24,000-volt bus. They introduce 5 per cent reactive drop between the sections when 50,000 kva. are being transferred. The housings are supported on insulators and are connected to a ground bus.

Bus-sectionalizing reactors were in some instances provided with disconnecting devices which automatically break the circuit when the reactor is removed from its operating location.

Representative opinion has been secured on the desirability of including in the new A. I. E. E. Standard for Fault Current Limiting Devices the material on reactors now in A. I. E. E. Standards No. 13 and also information on grounding transformers, generator neutral reactors, and Petersen coils. As yet no definite decision has been reached.

INTERCONNECTIONS

Report of Joint Subcommittee

The work of the Joint Interconnections Subcommittee has related almost entirely to the preparation of papers. A comprehensive paper on *Present Day Practise in Grounding of System Neutrals* was prepared by the subcommittee and presented at the Pittsburgh District Meeting.

A paper entitled *Impulse Test on Substations*, by Messrs. Brookes, Southgate, Roman, and Whitehead, was presented at the Winter Convention.

The following papers were presented at the Pittsburgh Meeting:

Committee Report on Present Day Grounding Practises, C. A. Powel, Chairman.

Reactance of Transmission Lines with Ground Return, J. E. Clem, General Electric Company.

Power System Voltages and Currents Under Fault Conditions, R. D. Evans and S. H. Wright, Westinghouse Elec. & Mfg. Company.

Simultaneous Faults and Six-Phase Transmission, Edith Clarke, General Electric Company.

Power System Voltages and Currents Under Fault Conditions, R. D. Evans and S. H. Wright, Westinghouse Elec. & Mfg. Co.

Series Resistance Method of Increasing Transient Stability Limit, R. C. Bergvall, Westinghouse Elec. & Mfg. Co.

Research

ANNUAL REPORT OF COMMITTEE ON RESEARCH*

DURING the year the Committee members have reviewed twenty-six papers and recommendations have been made to Headquarters for their disposition. Each paper has been reviewed by three or more members and outside experts. The Committee held one session at the Winter Convention at which eight of the approved papers were presented. Additional papers, obtained through the Committee on Research, are scheduled for the Summer Convention and several papers made available for district meetings. All business was carried on through correspondence as the only Committee meeting scheduled, at the Winter Convention, had to be abandoned because of conflicts.

The following topics are of sufficient importance to be called to the attention of the electrical engineering profession. The subjects reported have all been suggested by the Committee members, special assistance having been given by Messrs. W. G. Cady, V. Karapetoff, H. H. Race, D. W. Roper, T. Spooner, and J. B. Whitehead.

PHYSICS

In the field of physics there has been a number of theoretical and experimental accomplishments of some interest during the past year.

The knowledge of cosmic rays has been advanced somewhat with two schools of thought: certain investigators, as a result of certain experimental evidence, are convinced that cosmic rays are actually high velocity particles. However, Dr. Millikan, from intensity measurement of the cosmic rays in northern latitudes, feels quite certain that they are actually rays, since they are not affected by the earth's magnetic field. Dr. Millikan concludes that the cosmic rays have their origin not in the stars, but in interstellar space and that they are due to the building up of the commoner heavy elements from hydrogen, it being thoroughly established by spectroscopy that hydrogen is widely distributed through space. Several of the more common elements and also helium exists in interstellar space.

After seven years of intensive work, Dr. Paul Heyl of the Bureau of Standards has remeasured the constant of gravitation, or as the newspapers would put it, the weight of the earth. This figure is 6.670×10^{-8} c. g. s. units.

Eddington has developed a theory which makes possible the calculation of the ratio of masses of an electron and proton as well as the sizes of the electron and of the universe.

The generation of very short radio waves is possible by a number of means, among them the Barkhausen tube. This tube is a three electrode tube with suitable voltages applied to the grid and plate and provided with parallel Lecher wires. The frequency is dependent on the speed of the electrons as affected by the voltages and spacing of the electrodes and is independent of the external characteristics. Shuster has applied quantum mechanics to the problem of the Barkhausen tube and has calculated correctly the observed frequencies.

---

*COMMITTEE ON RESEARCH:

L. W. Chubb, Chairman,
H. D. Arnold,
E. Bennett,
W. G. Cady,
E. H. Colpitts,
E. C. Crittenden,
W. F. Davidson,
W. P. Dobson,
F. M. Farmer,
J. Allen Johnson,
V. Karapetoff,
A. E. Kennelly,
J. K. McNeely,
F. W. Peek, Jr.,
H. H. Race,
C. W. Rice,
D. W. Roper,
T. Spooner,
J. B. Whitehead.

As a result of the work of Grondahl it has been known for some years that copper oxide on copper had a photoelectric effect, making possible the generation of electric energy from sunlight. Dr. B. Lange of the Kaiser Wilhelm Institute for silicate investigation has obtained some interesting results with the copper oxide cell. According to newspaper reports he has, with the use of silver selenide, obtained similar results, but of one hundred or more times as much magnitude. However, for the generation of power from sunlight, the development is very far from being commercial owing to the high cost and low output.

Medicine and Physiology

In the realm of medicine and physiology there has been a number of developments of interest to the electrical engineer. The recent paper on "Experiments on High Voltage Tubes," by Tuve, Hafstad, and Dahl of the Department of Terrestrial Magnetism, Carnegie Institution of Washington, describes an X-ray tube, the voltage of which can be as high as 2,000 kilovolts. At 1,300 kilovolts the absorption coefficient, after filtering through one inch of lead is the same as that for the gamma rays from radium in equilibrium measured under the same conditions with the same instrument. This result has been attained by the so-called heat working of the pyrex glass. This high voltage tube should serve as a new tool to the medical profession.

For the treatment of cancer there has been developed by Dr. W. D. Coolidge a 900,000-volt X-ray tube to be installed in the New York Memorial Hospital.

It is well known that fever assists in destroying certain disease germs. It is possible, by the use of high frequency electrostatic fields, to produce artificial fever, thus assisting nature. Considerable success has been obtained by this method during the past year.

Dr. George Sperti of the University of Cincinnati has succeeded in using selected regions in the ultraviolet spectrum for the irradiation of foods; for example, he has been able to create Vitamin D in milk without spoiling the taste.

Dr. H. C. Rentschler has developed a method for measuring ultraviolet radiation by the use of a suitably designed photocell and a condenser. The condenser is charged slowly through the photocell and discharges through a counter at a rate dependent upon the ultraviolet radiation received by the photocell.

Dielectrics

Considerable progress has been made in insulation and dielectric research during the past year. Much work is being done to improve the processing in the manufacture of high-voltage cable insulation and also to detect a faulty impregnated cable before it goes into service. At Johns Hopkins University the value of thorough drying by the use of vacuum and air pressure during impregnation and the use of gas free oils have been studied further. To detect poor insulation, research workers of the University of Illinois are measuring high frequency discharges which constitute internal ionization.

Studies on the oils themselves are under way at the Detroit Edison Company, Cornell University, and the Brooklyn Edison Company, with special emphasis on the life characteristics and products of such oils under electrical stress, particularly ionic and electronic bombardment. At the Detroit Edison Company, it has been found that by bombardment of the oil vapors in a vacuum, the composition of the gas produced varies from one hydrocarbon to another and is quite complex, but consists roughly of 50 per cent hydrogen and 50 per cent unsaturated hydrocarbons. Liquids and wax-like solids are also produced. The solid formed is a duplicate of the compound "X" found in cables which have been in service. The formation of this substance in cables indicates internal corona. Five normal paraffin hydrocarbons of simple chemical structure and of very high purity have been prepared at the Bureau of Standards and studies are being made of their electrical characteristics.

Further studies have been made of polar compounds in liquid dielectrics. The frequency-temperature-loss characteristics have been studied in a number of laboratories with most interesting results. In addition, the polar characteristics of certain commercial insulating liquids are being studied, particularly the change and polar characteristics during service. These fundamental studies should aid in a choice of better insulating oils.

At Johns Hopkins University correlation between d-c. absorption and a-c. dielectric loss has been verified for several oils, dried paper and impregnated paper consisting of the materials previously studied alone. The relatively high d-c. conductivity of oil obtained up to about one second after electrification was found to account for the a-c. losses. The electrical characteristics of the separate and combined materials of impregnated paper insulation have been studied. This is a very important step in the fundamental side of dielectric research.

Another field of investigation which is just getting under way is the use of X-rays to study the molecular structure of dielectrics. The work of Dr. Zwicky at the California Institute of Technology on mosaics and on sodium chloride crystals, and the work in Chicago by Dr. Bennett on the effect of an electric field on the arrangement of paraffin crystals are worthy of notice.

There have been numerous important and interesting engineering developments during the past year.

LIGHTNING RESEARCH

As the result of the investigations of natural and artificial lightning carried on at a number of field stations in various parts of the country, it has been pretty definitely established by the use of the cathode ray oscillograph that most outages and damage to transmission lines are the result of direct strokes rather than induced lightning. Two records during 1930 were obtained of crest values of 4,500 and 5,000 kv. The latter value was recorded at a distance of several miles from the stroke. At the place of flashover it is estimated that the potential was at least 10,000 kv. It has been concluded that a lightning stroke to a ground wire, if flashover does not take place, does not result in a surge over the line. By using proper precautions it is believed, as a result of these lightning investigations, that it will be possible to build transmission lines which will be practically immune from lightning.

There have been developed and placed on the market during the year, two new types of lightning arresters, namely the thyrite arrester by the General Electric Company and the new porous block autovalve arrester by the Westinghouse Elec. & Mfg. Co. These arresters have characteristics which are considerably superior to their predecessors.

The commercial development and application of new types of discharge tubes have been very active recently. It seems evident that these devices are going to occupy a very large place in the control and conversion of power.

RADIO

In connection with radio there have been developed and put into commercial operation, 200 kw. transmitting tubes for broadcast stations.

Mercury-glass three-phase rectifiers have been developed to supply plate current for these high power radio tubes. These rectifiers are rated at 10,000 volts and 30 amperes. Additional grid-controlled gaseous discharge tubes, namely, the Westinghouse grid glow tubes and the General Electric thyratrons which are similar in their characteristics, have been developed during the year, the larger sizes being able to handle 75 amperes at voltages up to 1,000 or even 2,000. A grid energy of ½ watt or less is required.

Many new applications for grid glow tubes have been made recently. Among them is the theater light dimmer system which is controlled by very small rheostats which regulate the voltage applied to the grids of the tubes. These tubes supply rectified alternating current to choke coils which are saturated by the pulsating current, thus changing the inductance and controlling the lights. The small control wires can be led to any desired location, thus concentrating the control and simplifying the operation of the system. There are no moving parts and contacts, except for the small control rheostats. A very great advantage of this type of control is that the whole lighting program for the evening may be preset.

MISCELLANEOUS

A new stroboscope called a stroboglow has been developed, which illuminates a moving object for a period of only 3/10 of a microsecond or less. This interval is so short that an object moving at seven miles a minute appears to be perfectly stationary with no appreciable blur. No moving parts are necessary and no connection between the stroboglow and the moving object is required. The instrument is calibrated for frequency and may be used to determine the speed of rotation of the illuminated object.

A very small tube rectifier has been developed, rated at 3/10 of an ampere and 5,000 volts. This rectifier is 4½ in. long and 1¼ in. in diameter. It can be operated satisfactorily up to 10,000 volts and under special conditions, has been carried as high as 30,000 volts. These tubes are particularly suited for airplane radio transmitters.

A new oscilloscope with a linear time axis has been developed which employs a new type of cathode ray tube for its essential element. This oscilloscope has the advantage over previous types in that it has a larger field and the illumination is very much greater, making it possible to observe recurrent phenomena in a well lighted room. Non-recurrent phenomena lasting for a few microseconds, can also be observed readily for qualitative results. For recurrent phenomena the cathode beam may be synchronized so that the image appears stationary.

An automatic traffic control system has been developed and put into experimental use on main highways, using a beam of light crossing the side streets. When a car or other vehicle approaches the main highway on the side street, the beam is intercepted, thus causing a photocell to act giving the minor street the green light.

There has been developed in Germany another application of the light sensitive devices for the purpose of stopping railroad trains. Light from the headlight of the locomotive is reflected from a mirror on the semaphore and returns to photocells on the locomotive, which when illuminated operate the automatic stop mechanism.

There has recently come into general use in this country the electric photo-flash lamp which was developed in Germany and is used as a substitute for flash-light powder. The bulb contains a quantity of aluminum foil in an atmosphere of oxygen. A small filament, when heated electrically, causes the aluminum foil and oxygen to combine with an intense illumination. The elimination of noise and smoke is greatly appreciated by the average audience.

Studies and applications of piezo electric quartz crystals have been continued at Wesleyan University. By means of the cathode ray oscillograph, the rate of dying away of the oscillations of these crystal resonators has been studied. It has been found that a 600-kilocycle crystal started vibrating and left to itself, makes 60,000 vibrations before its amplitude falls to 1 per cent of its initial value. Various types of mountings for the crystals as well as the effect of the shape, cut and material of the crystal itself are being studied. A determination of the viscosity of quartz as a function of frequency is yielded by the above measurements. The coefficient of viscosity or quartz is approximately five at 600 kilocycles as contrasted with 500 for aluminum at 60 kilocycles and with values of the order of 10^8 ordinarily quoted for the low-frequency viscosities of metals.

A very accurate clock developed by the Bell Telephone Laboratories was exhibited at Cleveland last December, which is unique in that it is controlled electrically by a spherical quartz crystal.

The Stevens Institute of Technology reports the development of a clock which is automatically corrected by the standard radio time signals.

The limitations and advantages of commutation and current collection in hydrogen have been determined by laboratory and commercial experiments. In general, in the hydrogen atmosphere there results a lower contact drop. Satisfactory operation and long life are obtained if sparking is kept low. If appreciable sparking is present the humidity must be kept low.

The application of the helical groove to slip rings and commutators has been developed and applied commercially. Under severe conditions of commutation and current collection this apparently reduces brush wear and improves the electrical operation by reducing the formation of local hot spots; also better distribution of current between parallel brushes results.

A sample of commercial hipernik (a 50 per cent nickel-iron alloy) has been obtained having a maximum permeability of 167,000. Test samples from other castings have given as high as 13,000 for initial permeability and upwards of 400,000 for maximum.

Work during the past year on the fundamental nature of arcs and their extinction has given a greater insight into the problem of circuit interruption and is having a very definite effect on the design of circuit breakers.

There has been developed a non-destructive magnetic weld test meter for use with butt welds, which shows some promise commercially. For a given type of weld and a definite kind of steel, comparative results on welds are quite reliable.

At the Naval Research Laboratories interesting work has been done using the radiographic method for detecting imperfections in large steel forgings. Ordinary X-rays can penetrate only three or four inches of steel, but by the use of radium it has been possible to obtain photographs through twelve inches of steel. The radium has the advantage that it can readily be transported to the piece to be inspected and requires no complicated auxiliary equipment. If thick pieces of steel are to be photographed, however, either a long time must be used or a considerable quantity of radium or radium emanation must be available.

BURN-OFF characteristics of a-c. low-voltage network cables, exhaustively investigated through a series of field tests staged by a New York utility, are reviewed comprehensively in this issue. (*See pp. 662-4.*)

INSULATION research as reflected in recent Institute papers is reviewed in this issue (*see pp. 672-7*). Discussion offered at the recent summer convention reveals a decided difference of opinion as to the practicality of certain decisions reached through laboratory research. (*See pp. 683-4.*)

BENEFITS to civilization accruing from scientific and engineering advances are to be considered by eminent persons as a part of an ambitious publication program undertaken by The Engineering Foundation. (*See p. 689.*) The first of the proposed series of articles appears in this issue of ELECTRICAL ENGINEERING (*see pp. 641-4*); the editors will welcome comments, criticisms, and/or rebuttal.

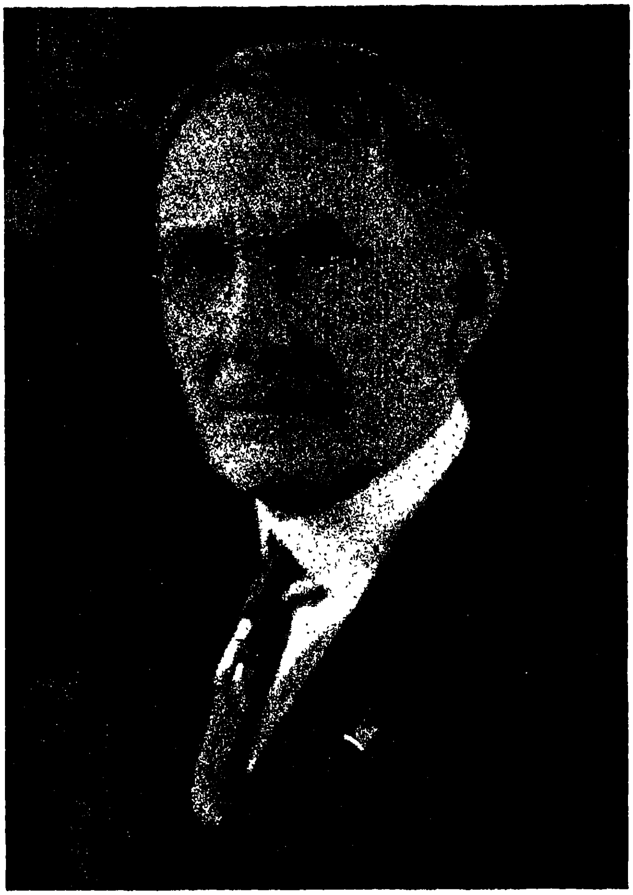
Doctor Skinner Takes the Helm

For the first time in his more than forty years of aggressive leadership in the electrical industry the Institute's new president takes a position vacated by another. Always he has pioneered, developing new processes, new departments, new products, new refinements; now he assumes leadership of the Institute. It is confidently to be expected that Doctor Skinner's pioneer spirit, keen foresight, and indomitable courage will prove invaluable to the Institute. His brief message follows.

FORWARD is the vital watchword, now as never before! We now are emerging from what perhaps is the most far reaching of the cyclic economic disturbances that have occurred during my forty-odd years of active service in the electrical industry. Far from being downcast, however, I have supreme confidence that we are at the beginning of an era even more significant in its possible advances than any that has gone before.

We are electrifying every industry. We may assume that the railroads are looking to electrification as one means of retaining transportation supremacy. Of profound significance is the fact that by far the most comprehensive railway electrification is being undertaken through a coordinated plan participated in by all parties at interest, including manufacturers and operators. Domestic application of electrical devices is only well begun and the next decade undoubtedly will see tremendous advances in this direction, releasing the household and farmstead from many drudgeries of the past and present. Thus, sketchily, we note that the electrical engineer is taking an ever increasingly important place in the affairs of the nation.

In all of this it is evident that the American Institute of Electrical Engineers has both a great responsibility and a great privilege to serve with increasing effectiveness its more than 18,000 members. To do this with a membership that is as diversified in its interests as it is far flung geographically, the Institute must go forward fearlessly, revising its policy and procedure as required to enable the best possible service to each individual member and each technical interest. Meetings must be arranged better to serve both the local and national interests of Branches, Sections, and Districts; publications must be developed to give to the specialist his detailed information and to the membership as a whole an accurate reflection of contemporary advances in the art and science of electrical engineering; members must be encouraged to participate more generously in Institute affairs; committees must be on the alert to develop their special fields. Progress in these directions already has been made; efforts under way must be pushed. However, in the final analysis, it is only through the loyal aid and wholehearted support of each individual member that real success can be achieved.



Charles Edward Skinner

A. I. E. E. president 1931-32

As for myself, I pledge my best efforts toward the advancement of the Institute in its many interests, and to uphold the best traditions of my illustrious predecessors. It is with confidence in the members of the Institute, confidence in the future of our industry, and confidence in the faith that the American Institute of Electrical Engineers can and will serve this industry ever more effectively, that I begin my term as its president.

CESkinner

Will Tuned Power Lines Eventually Solve Long Distance Transmission?

A new approach to an important problem in the field of electric power is offered by the author, who limits his discussion to the possibilities of tuned lines rather than their practical application. He presents the results of extensive research work, and on the basis of laboratory experiments points out that through the use of higher transmission frequencies, the efficiency of a given line might be increased as much as 500 per cent.

By
H. H. SKILLING
Associate A. I. E. E.
Stanford University,
California

LESS THAN 50 years ago when electrical engineering was young, there was vital and active interest in subjects which today are taken literally for granted. In early electric power work not the least of these was the question of choosing a desirable frequency for a-c. systems; 20 cycles, or 50, or 100? It was only natural that discussion pertaining to the frequency question considered principally the relative merits of different frequencies from the point of view of electric machinery—generators, motors, and transformers—with practically nothing said of the then simple subject of electric power transmission.

Thus it is that the large electric power networks of today find themselves definitely committed to certain frequencies earlier chosen for various expedient reasons. Now there is a definite trend toward the use of more and longer transmission lines for carrying large blocks of power from generation centers to load centers. In this connection the question of transmission stability is supreme; hence it is considered justifiable to reopen the question of desirable frequency, and to study it from the long lines point of view. It is well known of course that transmission characteristics of a given system may be improved by the use of frequencies lower than those now in vogue; but no general study of the influence of frequency has been published.

While the fundamental transmission line equations are:

$$E_g = E_r \cosh \sqrt{ZY}\, l + I_r \sqrt{\frac{Z}{Y}} \sinh \sqrt{ZY}\, l$$

$$I_g = I_r \cosh \sqrt{ZY}\, l + E_r \sqrt{\frac{Y}{Z}} \sinh \sqrt{ZY}\, l$$

where

E is voltage
I is current
g subscript, signifies generator end of lin
r subscript, signifies receiving end of line
Z is impedance per unit length of line
Y is admittance per unit length of line
l is length of line

it is most convenient to discuss transmission operation in terms of the general circuit constants:

$$A_o = \cosh \sqrt{ZY}\, l$$

$$B_o = \sqrt{\frac{Z}{Y}} \sinh \sqrt{ZY}\, l$$

$$D_o = \cosh \sqrt{ZY}\, l$$

$$C_o = \sqrt{\frac{Y}{Z}} \sinh \sqrt{ZY}\, l.$$

For ordinary transmission lines and for frequencies higher than about 10 cycles per sec., the value of factor $\sqrt{Z/Y}$ is practically constant and need not be considered as a function of frequency in this discussion. Hence the general circuit constants are proportional to the hyperbolic functions. However, if the resistance of the line in question is low compared with the reactance, and if the leakage from line to line is small, factor $\sqrt{ZY}\, l$ becomes purely imaginary and

$$A_o = \cos \sqrt{\mathbf{ZY}}\, l$$

$$B_o = j\, Z_o \sin \sqrt{\mathbf{ZY}}\, l$$

$$D_o = \cos \sqrt{\mathbf{ZY}}\, l$$

$$C_o = j \frac{1}{Z_o} \sin \sqrt{\mathbf{ZY}}\, l$$

[EDITOR'S NOTE: Bold-face symbols (**Z**, **Y**) indicate absolute values (magnitude only) time relationships as indicated by angles omitted.]

with $Z_o = \sqrt{Z/Y}$, the characteristic impedance of the line.

Thus it is made evident why low frequency gives good transmission characteristics. The desirable conditions are low voltage regulation under load, small charging current when lines are unloaded, and high synchronous stability. All three of these factors require a low value for B_o while synchronous stability requires also a value of A_o approximately unity. Both

---

From "Tuned Power Lines," (N . 31-124) to be presented at the A. I. E. E. Pacific Coast convention, Lake Tahoe, California, August 25-28, 1931.

of these conditions are obtainable with low frequency because Z and Y both are proportional to frequency, and as they decrease in value, the sine of $\sqrt{ZY}\,l$ decreases while the cosine of the same angle approaches unity.

Conversely undesirable transmission characteristics are encountered when the value of $\sqrt{ZY}\,l$ approaches $\pi/2$, because then the cosine approaches zero while the sine is near unity. Operation under such conditions is impractical because (1) regulation is so poor that with constant generator voltage the load is required to take practically constant current, (2) line charging current increases *indefinitely* as the receiving voltage rises, and (3) synchronous stability is possible only at extremely low power factor.

If the value of $\sqrt{ZY}\,l$ lies between $\pi/2$ and π, synchronous loading is quite impossible, but a static load may receive power. The static power limit (which is determined by voltage regulation and occurs at the load for which $d\,P_r/d\,E_r = 0$) becomes very large as $\sqrt{ZY}\,l$ approaches π, because $\sin \pi = 0$. For the same reason charging current to the line is very small; hence, transmission conditions are as good when the frequency makes $\sqrt{ZY}\,l = \pi$ as when the frequency is very low, except for the possible lack of synchronous stability.

An important point worthy of detailed consideration is that where the frequency used makes the value of $\sqrt{ZY}\,l$ slightly greater than π, and synchronous stability also is attained. The terminal steady-state conditions are identical when $\sqrt{ZY}\,l = k$ and when $\sqrt{ZY}\,l = k + n\,\pi$ with k representing any value of the function and n any integer. The truth of this statement for the idealized case under consideration is evident from the fundamental transmission line equations. The physical meaning is that transmission is good over a line the length of which is equal to a very small fraction of a wavelength of the transmitted voltage, and that it is equally good over a line the length of which is equal to a half wavelength or any multiple thereof. But this consideration includes only steady-state terminal conditions of a line without losses; certain modification is necessary before this statement may be considered to apply generally.

When line losses from resistance and leakage are not negligible it is best to use the hyperbolic-function form of general circuit constants. No change in the general understanding of conditions need occur, but the definiteness of the ideal line is lost; the power limit now is not infinite (as when $\sqrt{ZY}\,l = j\,\pi$) nor is synchronous stability either absolutely perfect or absolutely impossible. No longer is it quite true to say that $j\,\pi$ may be added to $\sqrt{ZY}\,l$ without changing terminal conditions. These things are nearly true, but not quite.

However, a point of far greater importance than line losses is the effect of terminal machinery. Even in the simplest system the general circuit constants will be modified by the generator, the transformers, and the load. If the apparatus at the sending end introduces a series impedance Z_1, and the receiving end apparatus introduces a series impedance Z_2, the general circuit constants become:

$$A_o = \sqrt{\cosh}\,\sqrt{ZY}\,l + \frac{Z_1}{Z_o}\sinh\sqrt{ZY}\,l$$

$$B_o = Z_o \sinh\sqrt{ZY}\,l + (Z_1 + Z_2)\cosh\sqrt{ZY}\,l + \frac{Z_1 Z_2}{Z_o}\sinh\sqrt{ZY}\,l$$

$$C_o = \frac{1}{Z_o}\sinh\sqrt{ZY}\,l$$

$$D_o = \cosh\sqrt{ZY}\,l + \frac{Z_2}{Z_o}\sinh\sqrt{ZY}\,l.$$

But if the line is long and the machinery is designed to have fairly low synchronous reactance, the only change in the constants that need be contemplated here is that a term must be added to B_o:

$$B_o = Z_o \sinh\sqrt{ZY}\,l + Z'\cosh\sqrt{ZY}\,l$$

where Z' is the total impedance of the machinery. This is an approximation, but it is almost true when the value of $\sqrt{ZY}\,l$ closely approximates π or is any multiple of π. It is not at all applicable if the value of $\sqrt{ZY}\,l$ approximates $\pi/2$, but it may be generally used because it applies whenever transmission characteristics are favorable.

Transient synchronous stability usually is investigated only after line and armature transients have died out; therefore as in the case of steady-state stability, only terminal line conditions are effective. A half-wavelength line would have the same order of transient stability as a low-frequency line except as the terminal machinery might be altered.

TRAVELING WAVES

The nicest description of the operation of a line is in terms of traveling waves. The generator may be considered as imposing on the line a series of electromagnetic waves which travel on the line to be more or less reflected from the receiving end, setting up a wave train traveling back toward the generator. Where the line is short a reflected wave returns to the generator so quickly after its initiation that it still is very closely in phase with the wave leaving the generator. Under this condition the voltages and currents of the two wave trains will add algebraically at the load end (assuming the load impedance to have the same angle as the characteristic impedance of the line) and differ by only a small angle at the generator end. Therefore, if attenuation is low the load voltage will be almost equal to, and in phase with, the generator voltage.

If the line be longer there will be a correspondingly larger difference in phase relation at the generator between the outbound and the returning wave. This involves trigonometric addition of effective voltages and currents at the generator and even with low attenuation, line regulation may be bad. However, if the line be of the proper length the reflected wave will arrive back at the generator just one cycle after its initiation there and consequently in phase with the next wave leaving the generator. Voltages and currents again will add algebraically and line regulation will be very good because the reflected wave will increase both end voltages equally. In this case as with the very short lines the load voltage will closely approximate the generator voltage (if attenuation is low) but 180 deg. out of phase.

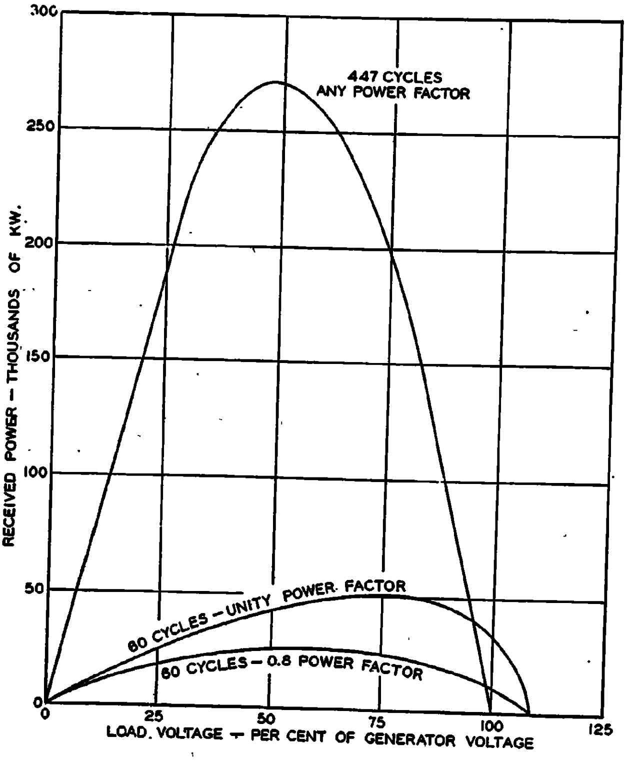


Fig. 1. Power limits of an operating 202-mi. 220-kv. line for normal 60-cycle operation and for suggested 447-cycle operation

The last few paragraphs have spoken of "long" and "short" lines. This refers to the electrical length of the line considering wavelengths rather than miles. However, a half-wavelength line is one for which the imaginary part of $\sqrt{ZY}\,l$ is $j\,\pi$, and hence it may be either a short line operating at high frequency or a very long line operating at normal frequency. Representative dimensions of a half-wavelength line are: 200 mi. long and 450 cycles, or 1,400 mi. long and 60 cycles.

The fact that apparatus at the ends of a line introduces impedance that increases the electrical length of the line already has been mentioned. It was shown that, approximately,

$$B_o = Z_o \sinh \sqrt{ZY}\,l + Z' \cosh \sqrt{ZY}\,l.$$

Since good transmission conditions demand that $B_o = 0$, it is desirable that

$$\sinh \sqrt{ZY}\,l = -\frac{Z'}{Z_o} \cosh \sqrt{ZY}\,l.$$

The hyperbolic cosine may be considered to be unity, either positive or negative. The lowest value of $\sqrt{ZY}\,l$ that approaches a solution of this equation will be between $\pi/2$ and π where the hyperbolic cosine will be negative and hence the values of frequency and length of line to be chosen should as nearly as possible make

$$\sinh \sqrt{ZY}\,l = +\frac{Z'}{Z_o}.$$

Consequently when terminal apparatus is considered, a shorter line or a lower frequency should be used than those given as representative in the preceding paragraph. If it is desired further to shorten the line or lower the frequency, more inductance may be introduced into the line, preferably in combination with static condensers across the line; this will result really in a section of "artificial line."

The presence or absence of synchronous stability for any given line may best be found graphically. Such methods, based on the circle diagram of the transmission line, tell at once the whole story of load limit, stability, regulation, and other factors. Although many statements in this paper now appear somewhat obscure in the light of the equations only, they become perfectly clear when the circle diagrams are studied. The diagrams unfortunately are too voluminous to be included, but Fig. 1 shows results obtained from such charts for a 202-mi. 220-kv. line having three 500,000-cir. mil cables spaced 15 ft. apart in a vertical plane; terminal apparatus not included. Under these conditions the value of sinh $\sqrt{ZY}\,l$ reaches a minimum at 447 cycles. Whether or not there might be synchronous stability at this frequency depends upon the synchronous machinery; it is probable that there would be. It may be seen that the maximum power per phase to be received at 60 cycles by a unity power-factor load is about 50,000 kw. Lagging power factors are much worse, and leading power factors are not much better. With transmission at 447 cycles the maximum power (if supplied to a static load or to an induction motor) obtainable is more than five times the 60-cycle limit.

The reason for the peculiar action of a half-wavelength line is essentially quite simple. The capacitance of the line is so balanced against the inductance of the line that the undesirable effects of both disappear. On an exact half-wavelength line with no losses and without load, with voltage maintained by a generator, the voltage at the receiving end would be equal and opposite to the voltage at the generator; in the middle of the line the voltage would be zero. The momentary charge at any point of the line would be proportional to the voltage; hence charging current would not need to be supplied from the generator, but merely would flow back and forth from one end of the line to the other each half cycle. Although there would be no current flowing at either end of the line, there would be a large current at the middle where the voltage would be low.

If load impedance were equal to the characteristic impedance of the line, current and voltage both would be constant along the line, but retrogressing angularly through 180 deg. The charging current would be passed on by each differential section of line to its neighbor as the voltage wave travels, finally to be used by the load.

If load impedance were less than the characteristic impedance, the current would be least at the middle of the line where the voltage would be highest. This resonant voltage rise is valuable because it makes efficiency and regulation of such a line better than could be obtained even from d-c. transmission; by proper insulation, reactance of the terminal machinery, and proper choice of the characteristic impedance of the line, resonant voltage rise may be prevented from becoming troublesome.

It is because of the interaction of the distributed inductance and capacitance that such a line is called a "tuned line." The similarity to a tuned radio circuit is striking.

As evidence that a tuned line will behave as predicted by the fundamental equations, power was transmitted at 60 cycles over a 1,468-mi. artificial line. The characteristics were those of the 220-kv. line previously described (which may be recognized as the Pit River line of the Pacific Gas and Electric Company, Calif.) and the potential used was 127 volts to ground, 0.001 of the real line voltage with a corresponding factor of 0.000001 for the power per phase as compared to the real line. The receiving end was arranged for loading with either a static impedance of any power-factor or with a single-phase synchronous motor. Extensive tests were made and the observed characteristics were found to be in close accord with the computed expectations; synchronous stability of the system was found to be exactly as expected. The half-wave-length line plus the reactance of the synchronous motor gave fair stability. The introduction of reactance into the motor leads was found to improve stability greatly, at the expense, however, of power limit. When the line was shortened to slightly less than a half-wave-length, it was impossible to keep the motor in synchronism; no synchronous power could be obtained although resistance loads continued to operate.

Fig. 2 shows reproductions of oscillographic records of voltages along the artificial line. Load impedance was somewhat less than the characteristic impedance of the line, and there was noticeable resonance. That the receiving voltage actually was lower than the sending voltage was due to the heavy load, the long line, and the unavoidable losses in the artificial line that do not properly represent a true line. Regulation would have been worse had the load been applied at an intermediate point.

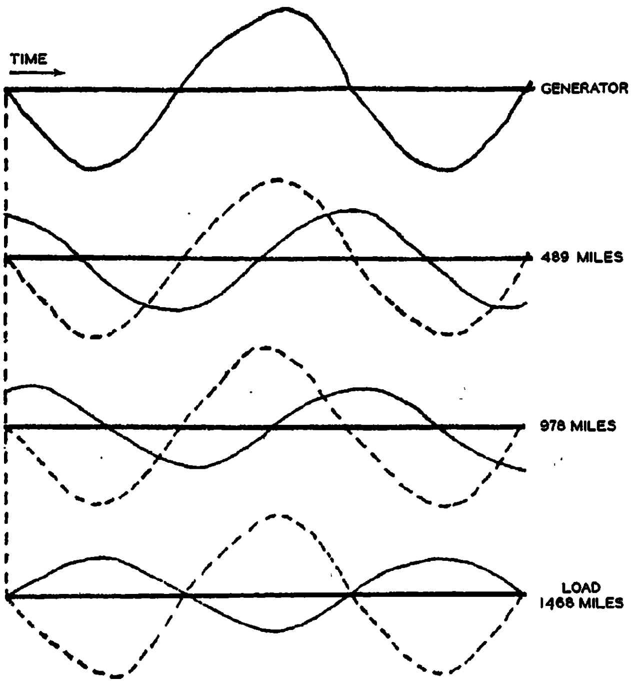

Fig. 2. Tracings from oscillograms showing voltage phase relations along a 1,468-mi. tuned line as compared with generator voltage (dotted)

While the subject of this paper considers the possibilities of the tuned line rather than its practical application and the details incident thereto, it seems quite reasonable to suggest that it is not at all impossible that 400-mi. transmission at 150 cycles will offer attractive economic possibilities. With the use of such a line of course motor-generator sets (probably induction machines) would be required for frequency-changing, but costly synchronous condensers would be eliminated. Even so considering the cost of building and maintaining 220-kv. lines it seems reasonable that even a relatively large amount of terminal equipment could be justified if it would eliminate one long line.

Present Practise in System Grounding

In this article are presented the principal findings of the Institute's joint interconnection subcommittee after canvassing 32 of the country's leading power companies. By comparing the results with those outlined in a similar report made in 1923, several noteworthy trends are indicated. Of particular note is a decided drift toward solid grounding.

TO OBTAIN A CROSS-SECTION of present day practise in grounding transmission system neutrals, the joint interconnection subcommittee of the power generation, protective devices, and transmission and distribution committees of the Institute submitted a questionnaire to 39 representative utilities throughout the United States; 32 replies were received. Data from these replies have been analyzed and condensed, and so far as possible are presented in this article in the form of tables and charts. In 1923 the protective devices committee through its subcommittee on grounding issued a similar report on the grounding practise of that day. Last year, however, it was felt that probably there had been sufficient change since 1923 to justify this second report.

The term "system" as used here may be defined as a certain number of circuit miles conductively connected; that is, connected by metallic ties. One company, therefore, may operate several systems, but on the other hand one system may overlap two or more properties. This designation is necessary because in the problem of grounding, the total mileage of the conductively connected transmission lines is of importance rather than the total mileage owned by any one operating company.

Methods of grounding adopted by the companies reporting are given in Fig. 1, which shows the longest single system and the average length of all the systems for each class of grounding. Where there are only two or three systems of one type they have been reported in full, since an average would not be representative.

METHODS USED ON SYSTEMS OF 110-KV. AND HIGHER

From the charts it may be noted that 93 per cent of the systems of 110-kv. and above are classified as solidly grounded, showing a marked preference for this type of grounding. Noteworthy deviations from this general practise are indicated as follow:

1. One company reports solidly grounded neutrals on its 132- and 66-kv. systems except at three substations, where from 53 to 75 per cent of the transformer capacity is grounded.
2. Another company grounds only one-third of the transformer capacity at one station, but the entire bank capacity at other grounding locations.
3. A third company reports using a resistance at the generating end of its 220-kv. system, but a reactance at the receiving end. This arrangement tends to decrease the angular swing between the two ends in case of a fault to ground, thus improving system stability.
4. Still another company is using an impedance grounding device in its most recent 220-kv. transformer installation.

There appears to be a tendency in the higher-voltage systems to limit the ground current by either impedance or resistance, or by a partial grounding of the total transformer capacity.

METHODS USED ON SYSTEMS OF 66-KV. AND LOWER

On systems of 66-kv. and less, the solid grounding practise is less prominent. As may be noted in Fig. 1, in this voltage range 51 per cent of the systems are solidly grounded, 9 per cent are grounded through resistance, 8 per cent are grounded through either reactors or grounding transformers, and 32 per cent have free neutrals. Of particular interest in this immediate connection are that:

1. Two companies report cases of reactance grounded substations operated in parallel with solidly grounded substations. This is done to obtain the desired distribution of fault current through the two or more grounding locations. Grounding a small transformer solidly obviously may be the equivalent of grounding a large transformer bank through an impedance so far as ground current distribution is concerned.
2. Another company reports the use of a Petersen coil. This report shows a marked reduction in the number of lightning interruptions during the year in which this coil has been in service.

In the case of the 11- to 14-kv. systems, an almost universal practise is to ground only one generator on each bus section. Four companies report grounding the generator bus sections through grounding transformers, while two use grounding reactors.

COMPARISONS BETWEEN PRESENT AND 1923 PRACTISE

In analyzing the results contained in this report E. C. Stone, who is responsible for the preparation of a major portion of the 1923 report, has drawn some striking comparisons between the two. One of these comparisons is shown in Table I.

From "Present Day Practise in Grounding of Transmission Systems," (N - 31-63) presented at the Middle Eastern District meeting of the A. I. E. E., Pittsburgh, Pa., March 11-13, 1931, and issued as the second report of the subject committee on grounding by the joint interconnection subcommittee of the power generation, protective devices, and transmission and distribution committees—F. C. Hanker, chairman. Personnel of subject committee on grounding:

TABLE I—COMPARISON OF PRESENT AND 1923 METHODS OF TRANSMISSION SYSTEM GROUNDING

	Present report		1923 report	
Method of grounding	Mileage	% of total	Mileage	% of total
Ungrounded	5,310	9.3	6,385	20.4
Solidly grounded	42,300	74.5	18,375	58.5
Resistance grounded	6,346	11.1	6,448	20.8
Reactance grounded	2,903	5.1	100	0.3
Total	56,859	100.0	31,308	100.00

While no radical changes in practise have been observed, some interesting trends are noted. The second report covers a total of nearly 57,000 mi. of transmission lines, as compared to about 31,000 mi. covered in the 1923 report. With the exception of approximately 5 per cent of the total mileage which is reactance grounded, all of the increase in mileage covered by the second report is solidly grounded.

In continuing Mr. Stone says that the present report clearly indicates a better understanding of the principles of system neutral grounding, of the fields for application of the various methods, and of the results to be expected. The points at which the neutral is grounded must be sufficient in number and so located as to permit adequate current flow regardless of the fault location. At the same time the neutral ground current must be limited to values which will not cause undue damage at the point of fault, and which will not produce system instability.

In discussing differences in grounding practise between systems operated at generated voltage and those operated at higher than generated voltage, Mr. Stone says in part that "of the 36,000 mi. of line reported on as operating at 34 kv. or above, approximately 34,000 mi. or 90 per cent are solidly grounded, while for the 21,000 mi. operated below 34 kv., only 55 per cent are solidly grounded. There are definite reasons for this difference in practise: on the high-voltage lines solid grounding gives greater benefits from the insulation standpoint, while at the same time the ground currents in relation to system capacity are relatively low; on the lower-voltage systems the fault ground currents are relatively large and the insulation benefits from solid grounding relatively small."

Mr. Stone expresses the belief that further analysis of the data will show that while the over-all grounded-neutral impedance may be lower than before, ground fault currents are still limited in value by the sectionalizing of the generating station buses. Thus a larger element of line impedance is introduced into the ground fault circuit than has been the case heretofore.

GROUND-WIRE PROTECTION AND TOWER FOOTING RESISTANCE

Over-all practise in the use of ground wires for the protection of transmission lines is shown in Fig. 2.

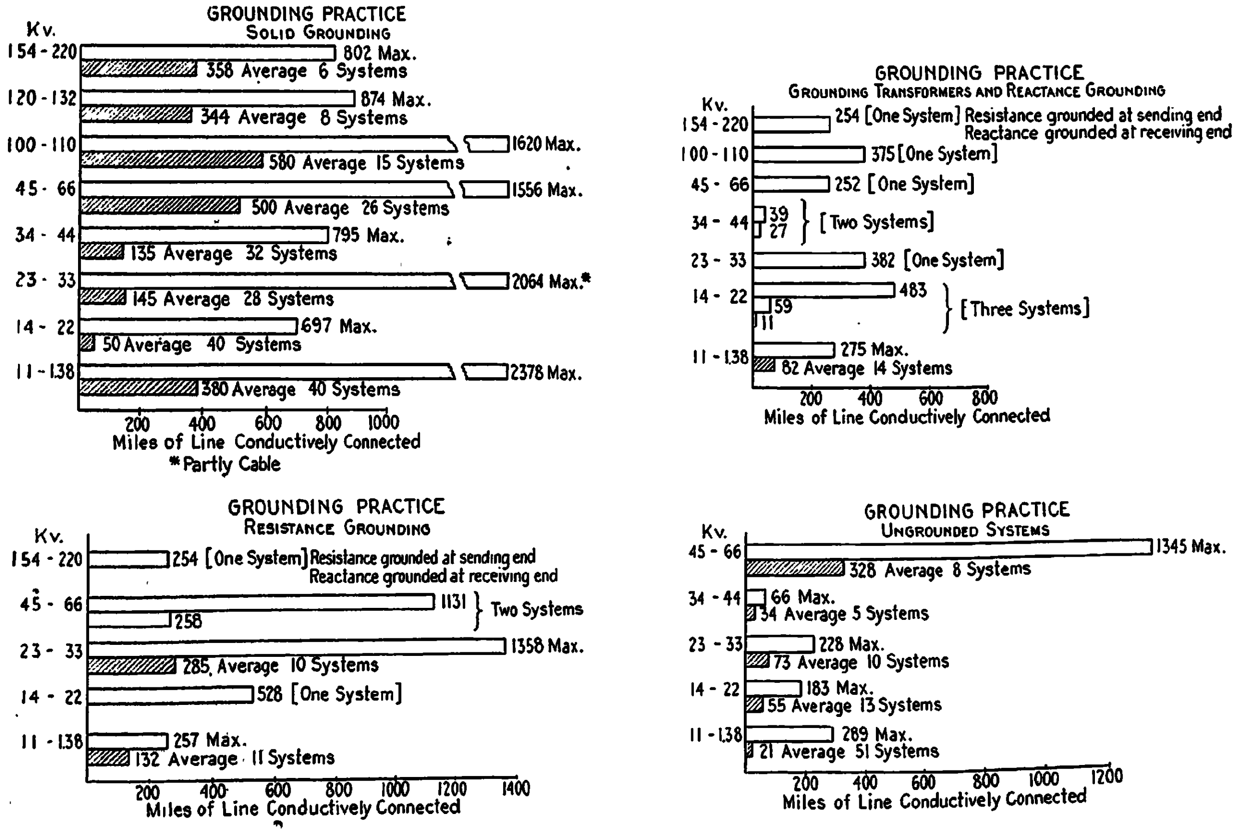

Fig. 1. Graphical summary of present day system grounding practise for different voltage ranges

In this graphical summary two different percentage bases are used as follow:

1. The total length of all lines reported in a given voltage class is taken as 100 per cent, and the mileage of lines protected by ground wires computed as a percentage of that total.

2. The total mileage in a given voltage class of each individual company is taken as 100 per cent, and the mileage of protected lines expressed as a percentage of this total. Averages of these percentages for each voltage class are the values given in the chart.

The former gives the practise of the country as a whole; the latter tends to show the opinion of transmission engineers better than the first value, perhaps, because the short systems are given the same weight as the long systems.

In protecting a line against direct lightning strokes, performance of the ground wire depends upon its receiving the direct strokes and conducting the energy to ground without causing flashovers to the line conductors. This depends upon the ability of the ground wires to remain at a low potential, which in turn is dependent largely upon the tower footing resistance.

Replies to the question regarding tower footing resistance, however, indicate that but few accurate data are available. Hence no average figures of any value can be given either on the basis of general territory or nature of soil. One company reports a range of from 1 ohm to 58 ohms over a restricted territory. The extremes reported by the seven companies replying to this question are 0.05 ohms and 300 ohms; the average 22.5 ohms.

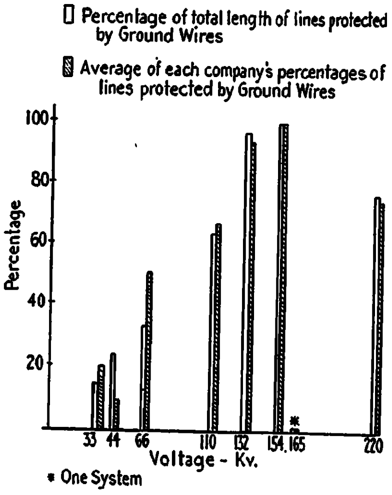

Fig. 2. **Graphical summary of present day practise in the use of ground wires**

SIMULTANEOUS FAULTS AT DIFFERENT LOCATIONS

In reply to the question, "do you have evidence of simultaneous faults at different locations," 25 replies were received. Of these, sixteen companies report no evidence; two report less than 1 per cent; three report 1 per cent; one reports 5 per cent, and three give replies as follow:

1. One company reports having trouble on a 300-mi. 66-kv. system until it was grounded. The neutral was found to shift to 80 per cent of the line-to-ground voltage at the middle of the section when one conductor was grounded.

2. A second company reports no evidence of simultaneous faults on their 132- and 220-kv. systems. One 66-kv. and two 22-kv. systems show 1 per cent or less, one 66-kv. system, 15 per cent, eight 26-kv. and three 13-kv. systems (mostly overhead) show 33 per cent, as indicated by relay operations.

3. A third company operating an ungrounded system reports conclusive evidence of arcing grounds without stating any figure for this type of fault.

In all cases, the evidence was taken from relay operations or from automatic oscillograph data.

In discussing this phase of the report Mr. Stone says that double simultaneous faults at different parts of a system are of particular importance because of the difficulties in many cases of providing relaying to isolate such faults without service interruption. Naturally in an ungrounded system simultaneous faults are charged to arcing grounds. In a properly grounded system arcing grounds should be impossible so that simultaneous faults here may be assumed to be the result of the rise in voltage on two phases when the third phase is grounded. The question then arises as to whether a relatively small reduction of fault voltage by lowering the ground impedance will correct the situation, or whether the insulation should not be sufficient to withstand these excess voltages for the short periods required for relay operation. The solution to this perplexing problem does not seem to be in reducing the impedance of the neutral ground circuit but rather in raising the system insulation to a level which will permit it to withstand the overvoltages prescribed by standard A. I. E. E. tests.

TYPES OF FAULTS

Regarding the division of the faults into the four classes, (1) one conductor to ground, (2) two conductors to ground, (3) phase-to-phase short circuit, and (4) three-phase short circuit, 27 replies were received. These are given in Table II as percentages of the total number of faults. The figures listed include both overhead and underground lines.

GROUND CURRENT AND RELAY OPERATION

All companies except two report sufficient current for relaying purposes. In these two exceptions a lack of proper selectivity was encountered at times of light load. Loss of synchronous load caused by ground faults is rare; only seven companies report having experienced this occasionally, while one company reports making changes in its relay equipment to rectify this difficulty.

TABLE II—DISTRIBUTION OF DIFFERENT TYPES OF FAULTS ON 27 SYSTEMS

	One cond. to ground	Two cond. to ground	Ph.-to-ph. short circuit	Three-phase short circuit
Maximum	97	45	54	36
Average	69	14	11	6
Minimum	30	0	0	0

In concluding his discussion Mr. Stone says that the problem of system grounding is only one phase of a greater general problem facing power engineers today—that of reducing insulation failures. However, because of the extensive research in progress, and of the definite advances being made, he urges an optimistic point of view on this subject.

Engineering and Human Happiness

THROUGHOUT THE AGES man has dreamed of relief from toil, of the bountiful supplying of his needs, and the attainment of comfort and luxury. He has struggled toward an ideal state in which these satisfactions might be enjoyed by all. From their beginnings the literature of all peoples has contained many expressions of man's aspiration for the "better life." Since happiness ever has been a condition earnestly desired by human beings the time seems propitious to ask—what has engineering done for humanity's progress toward this objective? What have engineers by their applications of scientific knowledge, by their control of nature's forces, by their improved and ever increasing utilization of new raw materials, or by their salvage of former wastes accomplished for the good of mankind.

For two years Admiral Byrd maintained 82 men under the most inhospitable climatic conditions to be found on earth! And they were comparatively comfortable and were happy in their adventurous enterprise. In contrast to the utter isolation of earlier exploring parties is the striking fact that throughout the period, persons in America and other regions thousands of miles away talked with him easily. Millions of men in all civilized countries daily heard by radio or read in their newspapers of the achievements, the dangers, the sports of this intrepid band.

On May 12, 1931, Capt. Frank M. Hawks flew from London to Berlin, arriving there ahead of a telegram despatched coincident with his start. On July 2, 1931, Gatty and Post completed in less than nine days a trip around the world. Startling exemplifications of engineering developments, these, and yet readers of morning newspapers hardly so much as wondered at the feats.

Daily, on the tables of millions of Americans of modest incomes are to be found articles of diet brought at low cost from places near and far by the most efficient transportation facilities the world ever has possessed. In the area known as continental U. S. A. perhaps as many as two million savages formerly sustained themselves precariously by hunting, fishing, and the crudest of agriculture. Within the same boundaries some 60 times as many human beings now possess means for supplying all their needs abundantly, together with many comforts and luxuries to say nothing of export. These multitudes also have facilities for education, many fine collections of art, and vast riches of other kinds such as even the kings and nobles no longer ago than when our grandfathers were boys could not have commanded.

Yet these items mention only a few examples of the many benefits which science, engineering, and chemistry have made possible within a half century to and through industry and commerce. How came these things to be looked upon as being so commonplace?

---

*Retired from office July 31, 1931.

An introduction to a series of articles in the course of preparation under the sponsorship of The Engineering Foundation. Not published in pamphlet form.

Modern man has come to accept as matters of course, one after another: unfailing supplies of good water conveniently delivered; sanitary disposal of sewage and refuse; more and better artificial light; steadily cheapening power conveniently applied; greatly improved facilities for communication (some of them almost instantaneous over long distances); better built and better equipped houses and working places; many means for rapid and enjoyable individual travel; commercial transportation remarkably low in cost and not only speedy, but also capable of carrying many commodities not formerly transportable; high explosives safe and convenient for many uses; recording devices that include besides the printing press, the camera, the phonograph, the "talking" film, and almost innumerable equipments and methods for special purposes; machinery for preparing and preserving foods in great variety; machines for making all forms of clothing and the materials therefor; novel equipment for entertainment and sports; farming implements; and tools of capacity, power, precision, and delicacy beyond the conception of persons unfamiliar with modern manufacturing.

These all are products of science, engineering, and applied chemistry, given to mankind through industry and commerce. It is of particular importance to note well also that progress made by science and engineering is ground *permanently* gained, a place from which to "take off" for further advances. Standards of living constantly are being elevated.

However, even the engineers, chemists, and industrialists who have provided present day society with its astounding equipment have given relatively little thought to the deeper effects of their achievements toward the lives and characters of men and communities and peoples. Of the painful present effects of individual and concerted neglect of immaterial (or spiritual) consequences, Progress is demanding a reckoning. Capacity to produce has been achieved; and the ability to discover and develop more and better goods and services made part of the world's present equipment.

But, how to divide the benefits of engineering progress properly has not yet been learned sufficiently well to permit maintenance through well ordered production, distribution, and consumption without disastrous fluctuation of enjoyment. Perhaps the methods of engineering and science could be applied beneficially to some features of this problem also, supplementing progressive business methods.

In an effort to effect a worthwhile contribution in this direction, The Engineering Foundation has invited an imposing array of highly qualified persons to comment upon various phases of the general subject of engineering developments' relationship to human progress and happiness. The first of these articles appears here; others are expected to eventuate.

Has Man Benefited By Engineering Progress?

A noted research worker, head of a modern laboratory, decides that the life of the future will simulate the life of the ancients; built, however, on a foundation of modern engineering.

By
C. E. KENNETH MEES Eastman Kodak Co.,
Rochester, New York

IN CONSIDERING the fundamental problem of whether engineering progress—under which term the engineer probably will modestly include the development of science and the arts through the ages—has been on the whole a benefit to mankind, it is necessary first to define what is meant by "benefit." This involves a consideration of the aim or purpose which may be ascribed to man's life on the earth.

This aim depends upon the person ascribing. The biologist probably would say that that purpose was the reproduction of the species; the mystic that the chief aim of man was to worship and glorify his maker; the materialist that it was to achieve happiness; while the Greek philosopher would say that it was to increase his knowledge of good. In considering the effect of scientific progress through the ages, therefore, one must consider its effect upon each one of these aims as well as upon any others which may occur to him.

If the purpose of the race is to multiply the species, then engineering progress certainly has been successful, since the population of the world is increasing rapidly and promises to become a very great problem in the near future.

To the mystic, the advance of civilization seems to offer no consolation. If man is more ethical than he used to be, he certainly is becoming less religious, and whatever future developments may show, at present engineering can claim no triumphs in the field of religion.

This leaves only the last two categories: the acquisition of happiness by the individual, and his progress towards a knowledge of good. It is under these two headings that my colleagues would think that engineering progress has been of benefit to mankind, including under the heading of *happiness* all the material benefits

---

First of a series of articles written expressly for The Engineering Foundation and released to ELECTRICAL ENGINEERING for publication. Not available in pamphlet form.

which it has conferred, and under the heading of *good* all the cultural and intellectual benefits.

Happiness, however, is not a thing which depends upon the possession of material things beyond a certain minimum. Happiness depends only upon the spirit, provided that spirit is not oppressed by the material situation of the body; it is fundamentally a by-product of activity of some kind. A man can be happy in arduous toil or in nerve-racking sport; he can be happy in intellectual relaxation; he can be happy, passively happy at any rate, in mere contemplation. Has not almost everyone heard of contented cows?

The one great gift of science to the world has been the diminution of disease. Diseases due to microorganisms, especially those which afflict the young, are diminishing rapidly as a result of the exploration of their natures and an application of the discoveries made. In their turn diseases due to deficiency are being diminished and eventually will be destroyed. One may look forward without doubt to a world in which widespread pestilences can exist no more. This certainly is a benefit to man which may be claimed by engineering.

But apart from this, I doubt if the life of the agriculturist in any country today is any happier than was that of a peasant in the Nile Valley 4,000 years ago. It is true that in the more advanced countries he has had great aid in his struggle with the pests that afflicted his crops and that in many cases as the result of applied engineering, he has had irrigation supplied, the first engineers to do this having lived more than 40 centuries ago. Moreover, in a few countries, and especially in the United States, machinery has reduced the heavy labor of the old-time farmer and has added many comforts to his domestic life. But, while machinery assisted the farmer at first, it now is undermining his status and perhaps may end by eliminating him. Hence the old normal life of man in which he cultivated the soil and lived on the crops, exchanging a small surplus for goods produced by somebody else, is passing possibly never to return. Engineering can produce that surplus and supply it to the consumer at a far lower labor cost than can the individual producer, and throughout the world economists and statesmen are considering the future of the farmer with troubled faces, remembering that farming is the normal life of man and that any other life for the mass of mankind involves tremendous readjustment in our whole economic and social system.

To turn from the agriculturist to the town dweller and even to the intellectual of the city, will any student of history agree that the inhabitants of an American city are any happier on the whole than those of a Greek or a Babylonian city of the past? This is a thing difficult to assess, but for myself, if I could exchange the life in a modern city for a life in Athens of the Periclean age or Thebes under the eighteenth dynasty, I think that undoubtedly I should accept it. In those days there was more leisure, more opportunity for the exchange of ideas, less pressure, and less emphasis on material things. There is little that a man can get today which he could not have had in Athens. It is better to walk a short distance than ride a long one. It is better to talk to one's friends and attend to one's business in a leisurely manner than to dash off to the office, returning in the evening tired. Life in a small city in a house with a garden is better, it seems to me, than is a life in the inevitable apartment of the large city. Perhaps it may be claimed that the urban worker has gained many comforts by the progress of engineering and that in recent years, at any rate, life in the sordid slums of our great cities has been mitigated by technical progress. It may be true that a factory operative in modern American textiles has a much greater chance of happiness than a corresponding operation in an Old World mill town of 70 years ago. But it seems to me that under those factory conditions of the first half of the nineteenth century the nadir of human existence was reached and that more properly the lot of the modern worker might be compared with the poorer classes of the great cities of the ancient world before the machines of the engineer had begun to replace the handwork of the craftsman. And I feel that a freeman of the Roman Empire, an apprentice of the middle ages, and perhaps even a Grecian Helot, had at least as good a chance for happiness as have most modern factory workers.

When one turns to the highest aim of mankind, that which we may define as progress in culture, it seems to me that the modern world is very much less satisfying than the world of the past. Culture primarily demands leisure, and at the present moment, at any rate, leisure is conspicuously lacking; it demands intellectual detachment, and intellectual detachment is exceedingly hard to accomplish.

Some of my colleagues may urge that engineering progress has contributed to international understandings; to this I would enter a definite objection. I doubt if nations ever have hated one another so fervently as they do at the present moment. Looking back on history, one can watch the waxing and waning of international good feeling; at the present moment it seems to me it is nearly at a minimum.

What then of the future? Shall scientific progress stop in an effort to get back to a world of the past? To this I should say that such discussion is futile. Scientific progress will continue and will be accelerated. In my opinion acceleration will end finally in a revolution of the whole social and economic life. What form that revolution will take and what type of life will come out of it, cannot be foretold, but I believe that in some respects the life of the future will be closer to the life of the past than to the life of today. I believe that a large portion of mankind will abandon the feverish quest for material things and will employ greater leisure for the development of art and the cultivation of its soul. This Utopia of the future may be possible primarily because of engineering progress, and in that sense engineering progress may be at some time a blessing to mankind. Up to the present time I doubt whether on the whole it has been.

Editor's Note: Pursuant to the invitation of The Engineering Foundation, the editors will be happy to receive comments, suggestions, criticisms, or discussions pertaining to this or the other articles published in this series.

An A-C. Network for Portland, Oregon

An underground distribution system comprising duplicate 11-kv. primary feeders and an isolated network secondary system is adopted to supplement existing d-c. and radial 2.4-kv. systems. Provsion for burn-off is not made; special junction boxes were developed.

By
S. B. CLARK
Non-member

N. W. Electric Co.,
Portland, Oregon

IN COMMON with other utilities serving areas of relatively rapid load growth, the Northwestern Electric Company which serves portions of Portland, Oregon, recently was faced with the problem of congested underground feeders and the prospect of further load growth. To supplement the three-wire d-c. Edison system originally installed in 1914 to serve the downtown underground district, the company placed in service in 1920 several radial a-c. three-phase 2.4-kv. primary feeders, later networked for load transfer purposes. At the same time radial secondary circuits connected to duplicate single-phase transformer banks for 120-240-volt lighting, and to closed-delta banks for isolated power loads, also were installed. In 1930 the company completed further steps in its distribution system development, initiating an 11-kv. duplicate primary, 125-216-volt Y radial secondary distribution system differing in some respects from any system now in use.

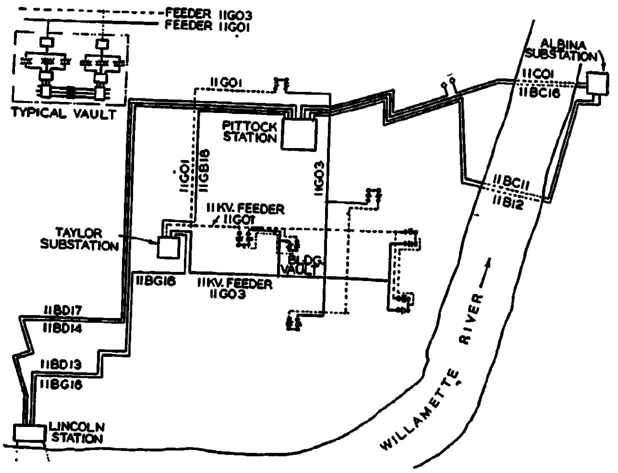

Fig. 1. 11-kv. underground distribution system of the Northwestern Electric Company, Portland, Oregon

In making the economic studies preceding the latest trend in the company's distribution practise, due consideration was given to the present a-c. and d-c. sectional load density and to capital investment in the existing distribution systems. Eliminating d-c. distribution as a factor in future demands, three types of a-c. distribution plant were considered, with capacities based upon anticipated load growth and costs estimated on each for purposes of economic comparisons. The three types were:

1. Expansion of existing 2.4-kv. three-phase primary network with radial single-phase and three-phase secondary circuits.
2. Expansion of existing 2.4-kv. three-phase primary along radial lines with four-wire 120-208-volt Y network secondary.
3. Installation of 11-kv. feeders with 125-216-volt Y secondary; the 11-kv. feeders to be (a) radial, (b) loop, or (c) duplicate.

Comparative cost data which influenced the final selection of system are given in Table I. All costs of course are based upon actual conditions peculiar to Portland, including the Pittock station's limited capacity together with its correspondingly large capital investment in 2.4-kv. station primary equipment and the large capital investment in a reliable 2.4-kv. distribution system, neither of which could be discarded within acceptable economic limits. Load forecasts indicated that the area of some 40 city blocks adjacent to the station eventually would develop a load demand equivalent to the existing capacity of Pittock station. Thus the development plan decided upon withdraws some of the longer 2.4-kv. feeders from sections outside that adjacent area, releasing station and feeder capacity for area use and picking up with the newer distribution plant the outside sections as well as extremely heavy concentrated loads within the adjacent area.

The cost data of Table I reveal the reason for the selection of the 11-kv. duplicate primary, 125-216-volt four-wire radial secondary for the Northwestern com-

(5) Single-phase paralleling reactors. (6) Pilot-wire cable junction box. (7) High-water float and control switch. (8) Sump-pump float control. (9) Sirocco ventilating fans. (10) Three-conductor lead-covered 11-kv. cable. (11) Single-conductor lead-covered 11-kv. cable. (12) 240-volt mains to sec. network. (13) System neutral. (14) Junction-box bus. (15) Pilot cable.

pany's Portland underground system. The slightly better cost showing of the 11-kv. loop system could not be realized practically, because proper sectionalizing switches with pilot relays and control were not available from manufacturers without appreciable development work. In passing it should be noted that had existing conditions been more favorable to the adoption of a more compact system, there would have resulted appreciable reduction in costs per kva. as compared with those of Table I.

The general plans of the 11-kv. tie-lines between the Lincoln steam plant, Pittock station, and Taylor and Albina substations, as well as the tie-lines for the network vaults now in service, are shown in Fig. 1. The Albina substation is the general distribution point for the company's hydroelectric power. Three-conductor 250,000-cir. mil, 15/32-in. paper, type-H cable was installed as the standard 11-kv. feeder. As may be noted in Fig. 1, taps from each feeder cable are carried into each vault with no switching protection provided except station circuit breakers between the station bus and station transformers. Either three single-conductor 250,000-cir. mil or 350,000-cir. mil paper cables (three cables installed in one duct and paralleled where load conditions demand) were adopted as maximum standard for secondary mains.

The standard vault provided for in this system plan is 22 ft. in length and 16 ft. in width with 10-ft. headroom. They are designed to accommodate duplicate banks of three 200-kva. single-phase transformers, with the secondary leads from each bank networked within the vault. However, the installation of the 200-kva. units will be made only when and as required by heavy concentrated building loads fed directly from the vault. In many cases three-phase transformers could have been utilized more economically than single-phase unit, but space restrictions in many important locations precluded the use of the necessarily large manhole openings.

Removable cell walls are provided to separate the 11-kv. transformers from the rest of the vault. The transformers used are of standard submersible network type with special low-voltage windings for providing the 125-216-volt Y instead of the usual 120-208-volt Y service. Three 2.5 per cent voltage taps are provided for increasing secondary voltage and special insulated studs extending through the transformer casing are provided to permit the expedient evolution of a three-phase closed-delta bank in the event of an extremely heavy power load being encountered with factors unfavorable for connection to the four-wire system. All transformers have an inherent impedance of 5 per cent.

General details of vault design are shown in Fig. 2. Special grounding and other safety precautions have been observed and a special pilot-light signal system conveys information to the Pittock station operator revealing to him the open or closed position of the 11-kv. network protectors, the presence of high water, or dangerously high temperatures in cables or transformers. This pilot system eliminates the necessity of constant inspection for operating information and also serves as an automatic indication of network switch position when a feeder is taken out of service.

Table I—Comparative Cost Data on Distribution Systems

System	Construction costs		Carrying charges		
	Per installed kva.	Per effective kva.	Investment 14% per kva.	Energy losses per kw-yr.	Total
D-c. Edison	$137.00	$137.00	$19.21	$20.24	$39.45
2.4-kv. a-c. radial	101.00	101.00	14.15	5.00	19.15
2.4-kv. a-c. radial primary with network secondary	117.00	119.00	17.00	5.00	22.00
11-kv. radial primary with network secondary	77.00	78.00	10.80	2.20	13.00
11-kv. duplicate primary with radial secondary	68.00	70.00	9.50	2.20	11.70
with network secondary	79.00	81.00	11.10	2.20	13.30
11-kv. loop primary with radial secondary	67.50	69.00	9.45	2.20	11.65
with network secondary	78.70	80.00	11.00	2.20	13.20

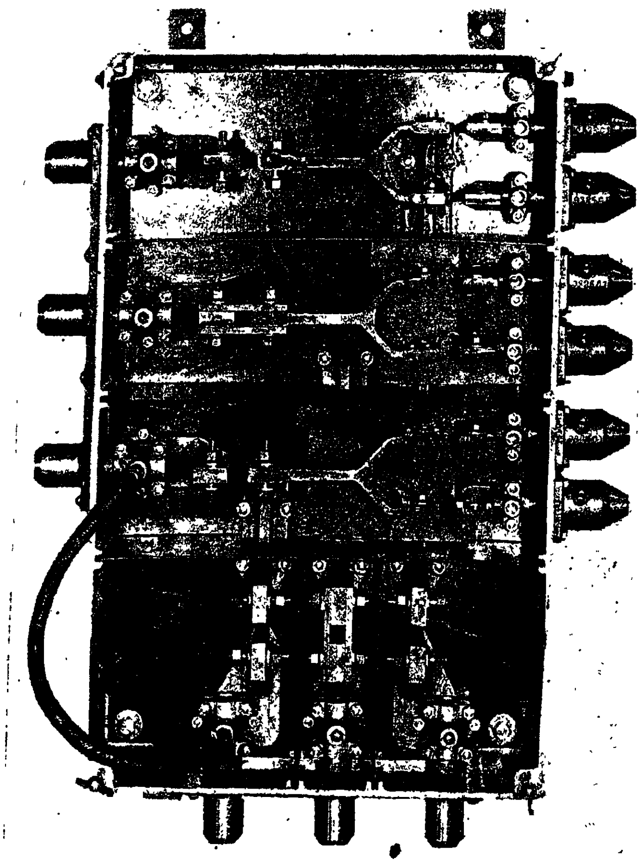

Fig. 3. Company's special design of junction box

During the study of existing network systems it became apparent that particularly along the Atlantic Seaboard, networks were being designed with an inherent ability to clear all secondary faults even at the expense of appreciable extra investment. However, on the basis of data available covering eastern operating experiences and construction costs, and on the basis of Portland operating experience which indicated that secondary faults rarely occur, it was decided that for the Portland system, additional capacity to provide for the burning clear of secondary-main faults was unwarranted. It was decided also that until results are available from wider operating experience, large solid-type networks should be avoided.

In view of the foregoing, and following the practise of some companies to insure against transformer damage or severe secondary cable burn-outs (especially where cables are mechanically injured) junction boxes were provided between network switches and outgoing conductors with both mains and services heavily fused. The first of these boxes to be installed were of standard manufacture and 1,200-ampere capacity; but the design did not prove to be entirely satisfactory. Thus a new design (Fig. 3) was developed and to date is assembled in the company's shop. The non-submersible case is of aluminum alloy (92 per cent aluminum, 8 per cent copper). Buses and terminals for the buses between boxes, and terminals for connection to network switches, have a normal rated capacity of 1,600 amperes, while the six terminals for main and service connections have a normal rated capacity of 600 amperes each. All unit parts are mounted on a separate practise of 1-in. ebony asbestos with barriers between conductors of opposite polarity. Buses are of single castings machined for linkage to network switch leads, junction box, connecting buses, and fuse positions to main and service leads. Submersible terminals are provided only for service and main connections to insure against moisture penetrating the paper insulation should the junction box become submerged. Where conditions require capacity for a heavy power load, and with a direct service into a building, power service is supplied from one junction box, while lighting service is taken from the other. Under these conditions the necessary reactance (item No. 5, Fig. 2) is connected in the buses between the two junction boxes.

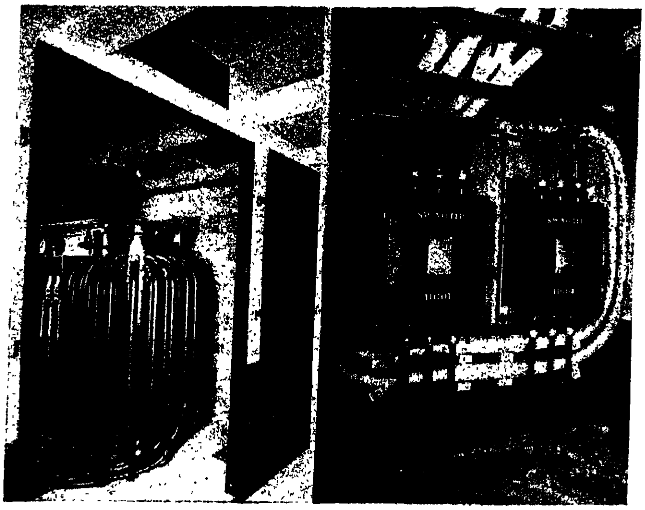

Fig. 4. 11-kv. basement vault construction

All new 11-kv. vaults are made waterproof in so far as possible, and without sewer connections although a small automatic sump-pump is provided to care for possible leakage. As ventilation becomes necessary a mechanical system of forced ventilation is installed. This ventilation system has been in use for some time on the 2.4-kv. distribution system, and includes a motor driven fan which discharges air through covered trenches in the vault floor, from which ducts lead into low metal cone housings at the bottoms of the transformers, thus forcing a thin sheet of air upward along each transformer casing, providing an effective and efficient means of cooling. The fan units are thermostatically controlled by transformer oil temperature, and as previously mentioned a high temperature alarm at the Pittock station is sounded by means of a contact-making thermostat in each transformer bank upon the event of dangerously high temperatures.

Vaults for 11-kv. primary, 125-216-volt Y secondary service often are placed within buildings, but under such circumstances cannot be standardized as readily as those in street areas, although of course certain identical features are retained. One example of a "near standard" is in service 64 ft. below street level in the subbasement of a department store. This vault is 25 x 27 ft. in plan with cell compartments for each transformer, and serves a demand of 775 kw. for lighting and 1,500 kw. for power.

The vault is supplied by duplicate feeders (Fig. 4 shows typical construction) each connected to two 450-kva. three-phase 11-kv./125-216-volt vault-type transformers connected delta on the primary and Y on the secondary. Secondary leads from each transformer feed through floor trenches to 1,600-ampere, three-pole open-type network protectors on one of the cell walls (Fig. 5). The load sides of the network protectors are connected to light and power buses suspended from the ceiling, the two buses being tied together by a smaller auxiliary bus to which the network mains from the street are connected. On this auxiliary bus, reactance is installed between the power and light buses to prevent objectionable voltage drop on the building lighting circuits.

In this installation all metering is accomplished by current transformers installed in the secondary light and power buses. Temperature and switch position indicators at Pittock station are provided as before mentioned, and telephone connection is provided between the vault, Pittock station, and the underground superintendent's office. Forced ventilation at the rate of 1,000 cu. ft. of air per min. serves to keep temperatures within desired operating limits. This building vault is networked through 1,600-ampere submersible network protectors to a street vault which contains six 150-kva. single-phase transformers with standard 11-kv. vault secondary connections.

The 11-kv. duplicate primary and isolated network secondary system has been in operation for several months, and to date no trouble excepting the necessary adjustment of network protector relays has been experienced. Three-phase motor operation has been entirely satisfactory on the four-wire system, even on the longer secondary mains. In cases where the d-c. or the three-phase a-c. power has been changed to the four-wire service, booster transformers to obviate any possible chance of voltage complaint have been installed in all cases where large ranges, bake ovens, lead melting pots, or other similar concentrated loads are encountered.

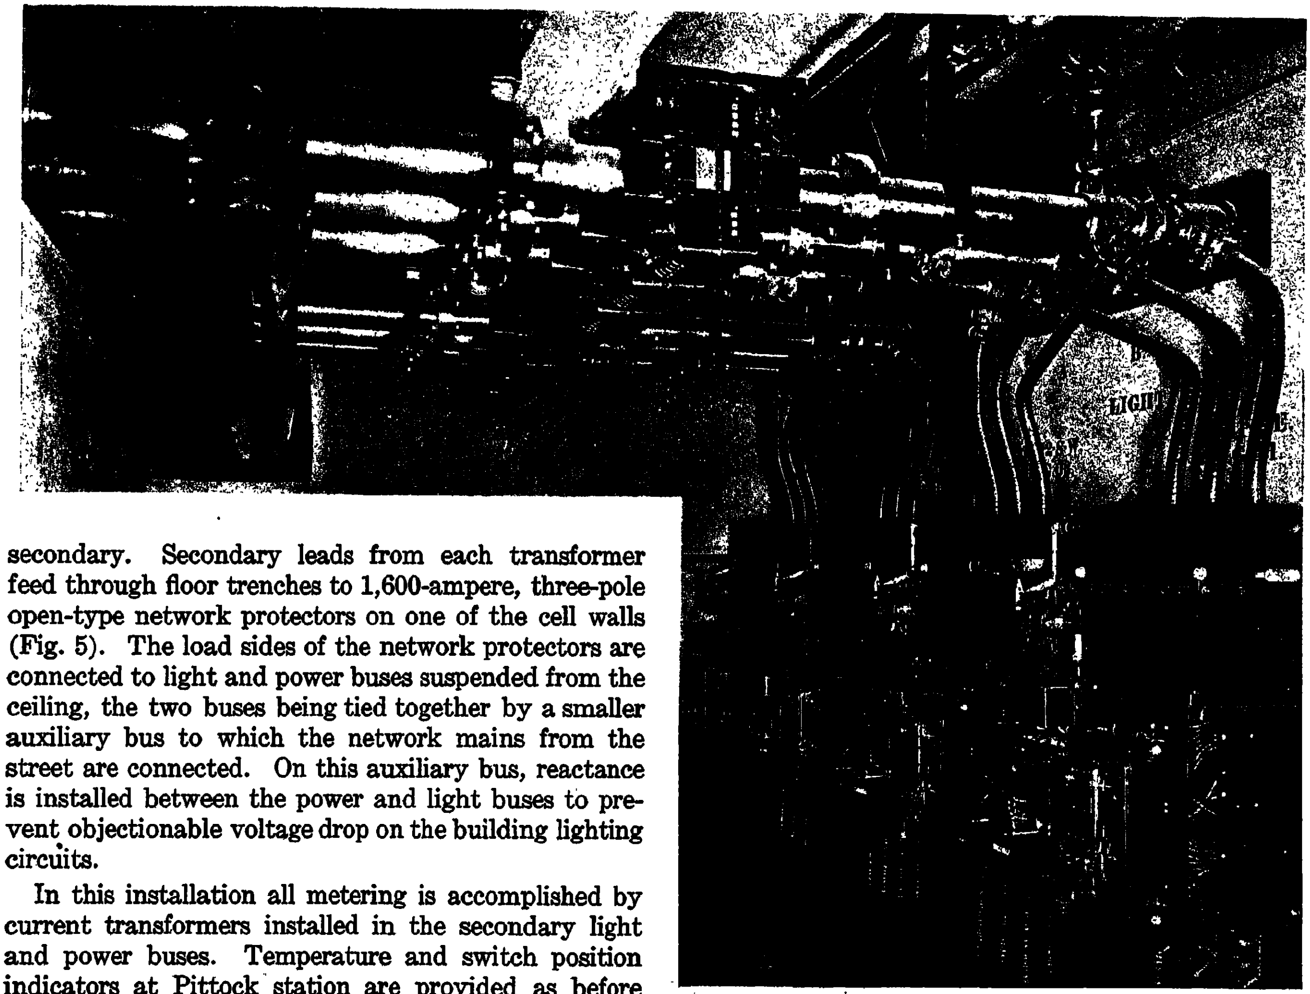

Fig. 5. Secondary construction in basement vault for store light and power service

Development of Gaseous-Tube Lighting

By
D. F. MOORE
Fellow A. I. E. E.

Consulting Engineer
East Orange, N. J.

Although what appears to be a multiplicity of different types of gaseous-conduction lamps have been developed, these are classified into a total of only sixteen groups. Outstanding developments in this class of lighting also are described in this article.

ALTHOUGH LIGHTNING represents a form of gaseous-conduction lighting which was observed by man millions of years ago, there are in practical use today only two general classes of gaseous-conduction devices. These two classes include (1) the non-luminous type—X-ray tubes, radio, and similar tubes, and (2) the luminous type to which this and the succeeding article are devoted. Although hundreds of devices in this second general classification appear to differ greatly in appearance and construction, they can be divided further into two general classes: (1) those of the positive column, and (2) those employing the negative glow. If each of these two classes is further subdivided into high- and low-voltage lamps, respectively, and these again subdivided into convenient groups, a total of sixteen groups of these lamps will result and under these practically all gaseous conduction tubes of the luminous type can be classified. (See accompanying tabulation.)

Perhaps best known among the various types of lamps are those of groups 1 and 9. Those of group 1, composed of script signs now popularly called neon signs, have grown so numerous during recent years that they have been said to "paint red the main streets of the whole world.". Those in group 9, of which the ordinary photographer's mercury-vapor lamp is a familiar example, came into use as early as 1895. Although at present these two groups are the most widely used of any of the sixteen, it should be borne in mind that any group at any time may assume increased importance.

The complete history of luminous gaseous-conduction lamps would read in much the same manner as that of many other outstanding developments of the present age. Like other developments, the present state of the art has been made possible only through a long period of research, many different investigators working independently and contributing to some one particular phase of the problem. It may be interesting, however, to note a few of the outstanding achievements.

An early (1905) script sign

What may be regarded as a starting point of the present development in script signs took place as far back as 1858. A glass tube smaller than a lead pencil had a platinum wire melted into each of its ends; after most of the air within the tube was removed it was touched to a high-voltage frictional machine and its interior immediately assumed a luminosity of pinkish hue. About a year later the air in the tube was replaced by pure gases, while fourteen years later a similar tube was lighted from an induction coil which in turn received its current from a primary battery. This type of apparatus persisted until about 1890, when efforts were initiated to devise a lamp of this type which would operate from a low-voltage house-lighting circuit. Continued and persevering effort along this line has resulted in the present state of development of the low-voltage lamps; many of the outstanding features mentioned in the following paragraphs are the direct results of such efforts.

Mercury-vapor tubes as mentioned previously were first brought out in 1895. These early tubes operated on low voltage but required momentary high voltage for starting the discharge. The next few years witnessed some accomplishment in other directions, and in 1899 tubes about 1¾ in. in diameter and about 8 ft. long, provided with external electrodes, were used to light a three-story factory building by tuning them to reso-

---

Written specially for ELECTRICAL ENGINEERING and based upon an oral presentation before the Illumination Group of the New York Section, A. I. E. E., March 8, 1931. Not published in pamphlet form.

Classification of Gaseous Conduction Lamps

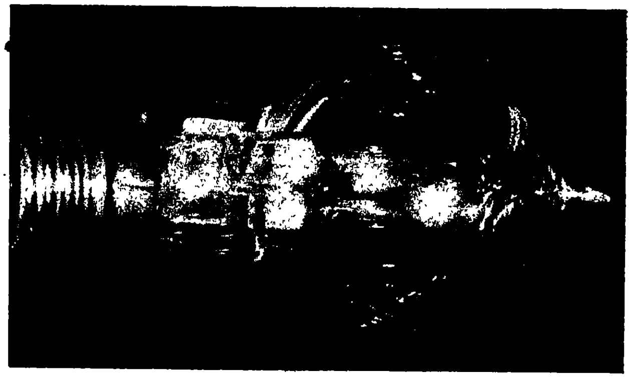
- **Gaseous Conduction Lamps**
  - **Positive Column**
    - **High Voltage**
      - 1. Script signs of the cold-cathode typ . These are in use now throughout practically the entire world, and are described in detail in the succeeding article.
      - 2. This group includes cold-cathod tubes from 1 to 250 ft. in length.
      - 3. Portable unit tubes of the cold-cathode type similar to those in groups 1 and 2.
      - 4. An ordinary incandescent lamp bulb of contemporary form with its filament replaced by a "gas filament" consisting of a fine-bore gas-filled glass tube.
      - 5. Tubes of the ordinary cold-cathode type used in a circuit tuned to resonate at the supply frequency.
    - **Low Voltage**
      - 6. Hot-cathode tubes designed to operate on low voltage without a special supply transformer. The electrode in this case is provided with a filament and associated circuit to reduce its potential drop. Tubes of this type can be modified for use on either a-c. or d-c. circuits.
      - 7. Tubes to operate on low voltage without a transformer or other potential-raising device. The main electrode is equipped with a small additional electrode; this electrode provides an electron gap which first functions on low voltage thus causing a long, positive column to form.
      - 8. Similar to group 7 except that bulbs of various sizes are used in place of tubes.
      - 9. Tubes in which the cathode electrode consists of mercury from which is produced the conducting mercury vapor.
      - 10. These are tubes with a cathode consisting of a steel button over which is compressed a heavy oxide coating for electron production, and penetrated by a small hole. These tubes constituted the first vacuum-tube rectifiers.
  - **Negative Glow**
    - **High Voltage**
      - 11. Tubes containing two parallel light-giving electrodes throughout their entire length.
      - 12. Bulbs with electrodes which when attached to a high-voltage circuit become surrounded with a negative glow.
    - **Low Voltage**
      - 13. Tubes with electrodes which shed corona light when attached to low-voltage circuits.
      - 14. Same as group 12 except that the gas content is neon. This is the commonly known "neon lamp" and can be adapted for television work by fitting it with two flat-plate electrodes about 2 in. square separated by a Crooke's dark space (about 0.01 in.).
      - 15. Cylindrical bulbs fitted with two internal cylindrical concentric electrodes. At the center of the inner electrode is a small cavity or crater which fills with an intense negative-glow light which projects itself from the end of the bulb only. The various sizes made require from 0.0001 to about 2.000 amperes.
      - 16. A bulb containing two tungsten-filament electrodes placed end to end with only a small space between. The light is due partly to corona glow, partly to incandescent tungsten, and partly to a tungsten arc. Usually these bulbs are charged with neon gas, but sometimes also contain mercury.

nate on a 25,000-cycle inductor generator used as a source of supply.

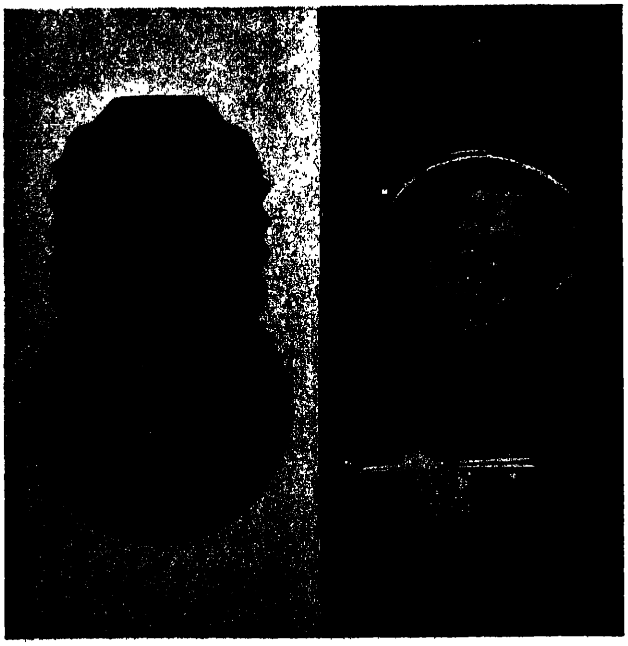
The year 1905 marked an important development in that the first script sign was put into use, and since that time the evolution of this type of light has been particularly rapid. The use in Paris in 1910 of nitrogen in a tube 150 ft. long marked one of these outstanding advances. Neon gas was introduced first into a bulb-type lamp with a gas filament in 1913. The significance of this step is too well known to require any further comment.

In 1915, however, an auto-thermic method of furnishing the carbon-dioxide gas then in common use was brought out; a lamp equipped with this device was said to give a perfect color value. Later this unit was made up with a 100-in. hairpin tube containing neon (exhibited at the New York Electrical Show in 1918) and its luminous efficiency was shown to equal that of the best incandescent lamp then available. Neon has found continued use through later developments right up to the present time not only for sign lighting but also for many of the other types of tubes and bulbs listed in the tabulation.

The future of gaseous tube lighting seems bright



A typical "gas-filament" lamp (group 4). Note that the metal filament is replaced by a fine-bore gas-filled glass tube



Two lamps of group 14. (Right) a television lamp; (left) an ordinary so-called "neon lamp" because its underlying efficiency, color, and intensity are all better than those possessed by the present solid conductor lamp. In addition manufacturers of solid conductor lamps today are resorting to inside frosting and exterior opalescent glass to increase the area of the light source; the gaseous tube possesses such properties inherently. That electro-luminescence will be "the light of the future," seems assured by recent advances which even now are causing the scientific world to expect still further developments.

Neon Tube Sign Lighting

The high-voltage cold-cathode neon tube as developed for commercial sign lighting is one of the few types of gaseous-conduction lamps to gain prominence. Their operating characteristics and associated transformer equipment are described in this article, and their advantages pointed out.

By
P. A. KOBER
Non-member

Claude Neon National Laboratories, Long Island City, N. Y.

IN THE DEVELOPMENT of neon sign lighting, great difficulties, and not a few, had to be overcome. As in other new developments, when the many obstacles encountered in the laboratory were surmounted, the additional problem of selling this new type of sign lighting to the public presented itself. That both difficulties were overcome is evidenced by the tremendous growth of the industry.

Although neon with its characteristic red glow was the first gas used for this type of lighting, a demand for other colors soon followed. Practically every color now is obtainable by utilizing the characteristic colors of other inert gases in clear glass tubing, and from mixtures of mercury and the inert gases in colored glass tubing.

Commercial neon sign lighting, however, as it is today, would have been delayed greatly had it not been for Georges Claude, a noted scientist of France. The value of his contributions, and particularly his success in the extraction, purification, and production of neon and other inert gases from the atmosphere, cannot be over-estimated.

NATURE OF GASEOUS DISCHARGE

Like the low-voltage gaseous conduction tube, the high-voltage tube belongs to the space-charge type, but differs from the former in that it may have either a positive or negative volt-ampere characteristic. The former is known as the arc; the latter as the glow discharge.

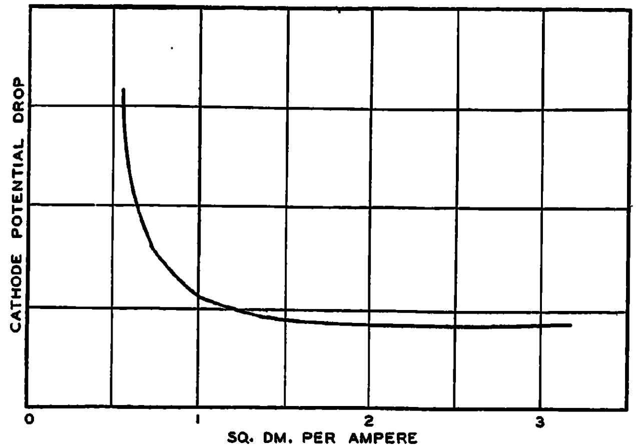


Fig. 1. Minimum cathode-drop characteristic for gaseous glow-discharge as obtained by Claude

No numerical values are given for the ordinate since these vary with different electrodes

In high voltage tubes of this type a high cathode potential drop exists which cannot be neutralized as is done in the hot-cathode type. This results in a certain amount of lost energy from which little or no light is obtained. Furthermore, this high-cathode drop, represented by a space charge consisting mostly of positive ions, tends to produce disintegration of the cathode by virtue of the relatively large mass and high velocity of these positive ions. In order to minimize disintegration by sputtering, and give a long-life tube, current values, electrode sizes, and gas pressures must be determined so as to keep the rate of sputtering sufficiently low; in other words, the mean free path of the positive ions must be decreased as much as other factors will permit, and the current per unit area of cathode must be made as small as possible. Claude has found that when the area of a cathode is in excess of 1.5 sq. dm. per ampere, the cathode drop reaches a minimum value (see Fig. 1).

Further explanation in regard to sputtering or disintegration of electrodes will not be amiss since, barring mechanical or electrical defects,* this phenomenon

---

Written specially for ELECTRICAL ENGINEERING and based upon an oral presentation before the Illumination Group of the New York Section, A. I. E. E., March 3, 1931. Not published in pamphlet form.

largely determines the life of the tube. The sputtering of electrode material forms a thin metallic film on the inside of the tube near the electrodes. It is known also that sputtering occludes the gas of the tube and thus diminishes the gas pressure, thereby increasing the mean free path of the positive ions. Since sputtering is caused primarily by the positive ions the net result is a cumulative increase in the tube operating voltage and also in the sputtering effect on the cathode. Finally, the voltage required to operate the tube becomes greater than that supplied by the transformer; at this point the sign begins to flicker and eventually goes out. The tendency to sputter varies with different metals but appears to be related to the latent heat of fusion, specific gravity, affinity for oxygen, and a number of other physical characteristics.

TRANSFORMER CHARACTERISTICS

To operate long tubes of small diameter obviously necessitates the use of a step-up transformer, since for the longest tubes an open circuit potential of about 15 kv. is required. With this high voltage, as might be surmised, many difficulties had to be overcome; principally those concerned with insulation.

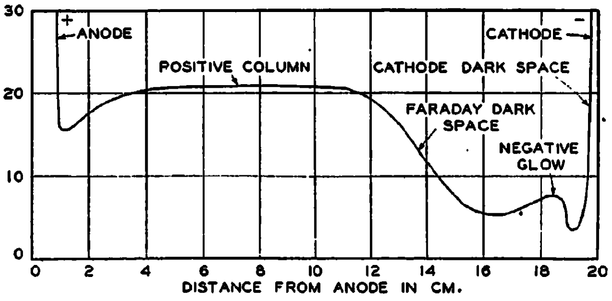

Fig. 2. Potential gradient for typical neon glow-discharge tube

Transformers now used are of the shell type, with a magnetic shunt inserted between the primary and secondary coils, to give high leakage reactance. With this arrangement the required qualities of exceptionally good current regulation and poor voltage regulation are obtained. The secondary terminals may be short-circuited without increasing the secondary current to any appreciable extent beyond its normal value. With the balanced-type transformer, which has a grounded center tap on its secondary winding, either high-voltage lead may be grounded without increasing the current (0.028 ampere) above that resulting from a terminal-to-terminal short circuit. Incidentally, this current is only about 0.006 ampere higher than that which constitutes a maximum tube load.

Transformers for commercial neon sign lighting, also must meet rigid specifications in their insulating qualities, and must be able to withstand about four times their maximum secondary operating voltage. This is necessary because in the actual operation of high-voltage tubes, high-frequency transients with high peak voltages sometimes occur and provision for this must be made.

Aside from the transformer, for commercial use the high-voltage cables connecting the secondary terminals to the tube electrodes must pass voltage tests 50 per cent higher than those specified by the board of underwriters. Good insulation between the tube electrodes and the grounded metal housing must be provided also; for this purpose porcelain or glass bushings are used. Owing to metallic dust or moisture accumulation on these parts leakage or brush discharge sometimes occurs at the bushings; however, with the balanced-type transformer used, electrode punctures and strains on cables are reduced greatly, since the maximum voltage between any point and ground is only about half of its former value with the older transformers.

TUBE CHARACTERISTICS

The varying potential gradient of a typical neon glow-discharge tube is illustrated in Fig. 2 while Fig. 3 shows the general shape of the volt-ampere characteristic for a glow discharge. As may be noted, from *A* to *B* the curve has a negative slope. This is due to the fact that the cathode drop remains normal up to point *B* while the voltage of the positive column, having a negative characteristic, decreases with the current. At point *B* (zero slope) the cathode drop becomes abnormal and just balances the positive-column drop. From *B* to *C*, the abnormal cathode drop with an increase in current, increases more rapidly than the positive column decreases; this explains the positive slope.

In Fig. 4 may be seen a curve showing how the volts per ft. of positive column vary with tube diameter;

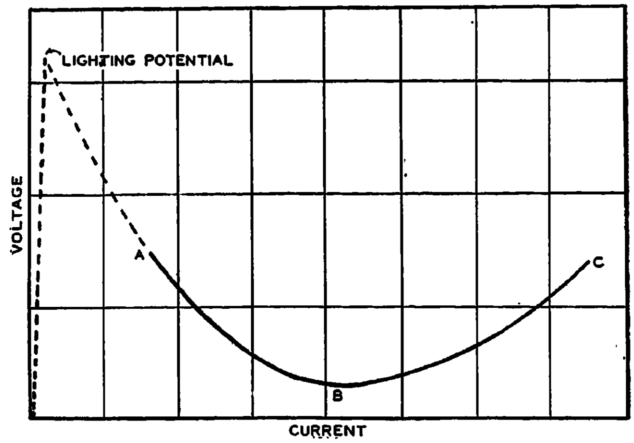

Fig. 3. Ideal volt-ampere characteristic for gaseous glow-discharg

No numerical values are given since these vary with other factors

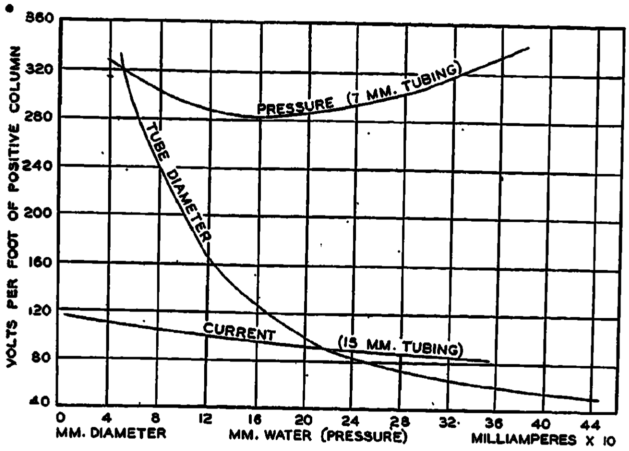

Fig. 4. Curves showing relation between volts per ft. of positive column and tube diameter; also typical curves for gas pressure and current

typical curves for current and gas pressure are given also. In general these will be found self-explanatory. Specifications for a typical neon sign installation are given in Table I. This will serve to summarize some of the points brought out by the discussion and curves.

TABLE I—SPECIFICATIONS FOR A TYPICAL NEON SIGN INSTALLATION

Tube	
Diameter	15 mm.
Length	60 ft. (4 tubes)
Gas	neon
Transformer	
Primary volts	110
Secondary volts (open)	15,000
Secondary volts (with load)	depends on tube length (max. 10,000)
Secondary milliamperes	25
Load watts	210
Volts per ft.	130
Watts per ft.	1.5
Lumens per ft.	36
Lumens per ft.-watt	24
Power factor	0.40 to 0.60
Life	10,000 to 15,000 hr.
Electrode drop per tube	250-300 volts

COLORS AND OTHER DEVELOPMENTS

As stated in the beginning practically all colors now are being made commercially by the use of the characteristic colors of the inert gases in clear glass tubing, and by the use of mercury and gas mixtures in colored glass tubing. It may be interesting to note here that a more efficient colored light can be produced from the characteristic glow of these various inert gases in clear glass tubing than can be obtained from incandescent lamps and filters. Significant also is the fact that the proper combination of colored tubes provides a true and efficient "daylight white" light source. Finally, an important feature of the light from gaseous conduction tubes is its uniformity of distribution and absence of glare.

Aside from sign lighting, high-voltage tubes are finding application as aviation indicators, beacons, showcase lights and for interior decorative effects. Ordinarily neon sign tubes have not lent themselves to moving effects as readily as have incandescent lamps. However, recent work in producing moving luminous phenomena in the tubes themselves such as moving "beads" and progressive lighting look promising.

The Propagation of Electric Waves

Progress made during the past year in the study of the propagation of electric waves is reported upon briefly by the A. I. E. E. electrophysics committee.

THE YEAR 1931 is the centennial of the discovery of electromagnetic induction by Faraday and by Henry; and also of the birth of Maxwell, the founder of the electromagnetic theory. It is appropriate, therefore, that a contribution of the A. I. E. E. electrophysics committee should deal with the propagation of electric waves.

Man now is employing and controlling electric waves of frequencies ranging from 0 to 10^{21} cycles per sec., but this discussion will portray the year's progress only in the lower portion of this range, for frequencies up to about 3,000,000,000 cycles per sec. Heat, light, and X-rays thus are disregarded.

ELECTROMAGNETIC WAVES ALONG CONDUCTORS

Propagation of electric waves along conductors is of interest to both the communication engineer and the power engineer. To the latter, one of the principal problems is that of the propagation of high-voltage waves, such as those induced by lightning.

Effects of change in circuit constants, effects of corona and other factors, and the changes in potential and in wave shape, all of which occur as such high-voltage

---

A progress report of the A. I. E. E. electrophysics committee. Not published in pamphlet form.

waves are propagated along power lines, have been studied by means of the portable cathode-ray oscillograph. Effects of change in circuit constants are discussed in a paper by McEachron, Hemstreet, and Seeyle (A. I. E. E. TRANS., Oct. 1930). In general, recent oscillographic tests on the propagation, reflection, and superposition of traveling waves have confirmed the purely theoretical predictions. Extensive oscillographic tests also were made to determine the effect of corona and other factors which decrease the potential and change the wave shape of high-voltage traveling waves. Oscillograms showing the effect of corona upon "artificial lightning" waves were especially important and interesting. These tests are described in a paper by Brune and Eaton at the Rochester A. I. E. E. District meeting April 29-May 2, 1931.

Cathode-ray oscillographic studies of the propagation of traveling waves in the armature windings of generators are described in papers by Boehne, and by Fielder and Beck (A. I. E. E. TRANS., Oct. 1930). The velocity of propagation in this case was found to be of the order of 10,000 mi. per sec. in the slots (Boehne).

Influence of the earth upon the propagation of electromagnetic waves along conductors has been subjected to much study during the year. Evans (*Phys. Rev.*, Vol. 36, p. 1,579, Nov. 15, 1930) has considered the case of a wire parallel to the surface of the earth with the earth itself as return, assuming a conductivity for the top stratum of the ground different from that of the remainder. Ollendorff (*Arch. f. Elekt.*, Vol. 23, p. 261, 1930) has dealt with this problem in considerable detail, being especially concerned with a top stratum of relatively high conductivity. Bowen and Gilkeson (JOURNAL A. I. E. E., Vol. 49, p. 657, Aug. 1930) have described some experimental results on the mutual impedances of ground-return circuits, checking the practical use of the theoretical formulas. Peterson (*Bell Sys. Tech. Jl.*, Vol. 9, p. 760, Oct. 1930) has discussed the transients in a similar case.

RADIO-WAVE PROPAGATION

While no important new discoveries in radio propagation seem to have been reported during the past year, there has been considerable progress in several lines of work which had been started during previous years.

Work with "ultra short" waves having lengths of less than 10 m. or frequencies greater than 3×10^7 cycles per sec., has become one of the major activities in wave propagation. Spurred on by the potential importance of these waves in communication, numerous workers have studied the phenomena qualitatively. Waves of lengths of less than 5 or 6 m. seem never to be reflected from the Kennelly-Heaviside layer. Therefore reception is not subject to fading, the name given to erratic fluctuations which are due to changing conditions in the ionized upper atmosphere and which are a source of considerable difficulty for waves longer than 10 m. However, phenomenally long ranges cannot be obtained. Transmission is best where an unobstructed optical path exists, but owing to the curvature of the earth such paths between points on the earth's surface are limited in length to the order of 100 or 200 mi. While an unobstructed path is best, these short waves will bend around obstacles, presumably by diffraction. As a result, the receiver may be located at points beyond the horizon of the transmitter, although there is a corresponding loss in transmission efficiency.

The extent to which reliance may be placed on diffraction obviously decreases with wavelength. For wavelengths in the order of 20 cm., it has been found, as expected, that an unobstructed path is essential; at any rate with the transmitting and receiving apparatus that has been available.

While an extended list of references cannot be given, the papers by Esau and Hahnemann (*I. R. E*, March, 1930) Jouast, (*L'Onde Electrique*, January, 1930) Ferrié (*Annales des Postes*, April, 1931) and "Micro Ray Wireless"—a new short-wave system demonstrated by I. T. and T. Laboratories, telephony on 18 cm. across the Strait of Dover, (*Electrician*, April 3, 1931) may be cited.

The role of the earth in radio propagation has claimed the attention of many investigators. Rolf (*I. R. E.*, March, 1930) has given curves which are based on Sommerfeld's well-known investigation and which makes this paper more useful to the engineer. Certain limitations in the applicability of these data have been pointed out by Wise (*I. R. E.*, November, 1930). The earth as a reflector of radio waves has been studied by Strutt (*Elek. Nach. Tech.*, February, 1930) Verman (*I. R. E.*, August, 1930) and others.

The Kennelly-Heaviside layer also has held the attention of many of the investigators. One of the more important results obtained has been the corroboration of the double-layer hypothesis advanced by Appleton. In this connection the work of De Mars, Gilliland, and Kendrick (*I. R. E.*, January, 1931) and of Goodall and Schafer (*U. R. S. I.*, May 1, 1931) may be noted. A minimum of effective ionization apparently exists between the heights of 110 km. and 250 km. In this work the echo method has been used to a considerable extent. Cases of relatively long delays due to slow group velocities under certain critical conditions have been observed and these may conceivably have a bearing on the very long delay echoes discovered by Hals and Stormer.

Hanson has presented orally some results on layer heights observed in the Antarctic by the Byrd expedition. It is of interest that even in the long winter night, reflections are obtained, although from greater heights than those found in other latitudes. In general, the phenomena were erratic.

The committee is indebted to K. B. McEachron, of its membership, and to J. C. Schelleng and J. M. Eglin of the Bell Telephone Laboratories, for material for this report.

Airplane Flight Aided by Electricity

By
C. F. GREEN
Non-member
General Electric Co.
Schenectady, N. Y.

Electrical instruments by giving accurate and reliable indications of direction, altitude, and of operating, traffic, and weather conditions, are contributing to safe flight even in dense fogs. Liberal use of instruments now available and development work along the line of new devices, are hastening the time when air transportation will compare favorably with other types.

AIR TRANSPORTATION in this country has witnessed remarkable growth. In a four-year period the ton mileage for mail and express transportation has been multiplied by 11 while passenger mileage over regular routes has been multiplied by 110. Other flying activities also have shown commensurate gains. Although regularity of service has increased, further progress is in order, for only when schedules can be maintained safely and on a basis comparable with other forms of transportation will the general public come to accept and depend upon air transportation. In this connection, however, it must be borne in mind that even the older forms of transportation are limited by many of the factors influencing air transportation. Railway trains still are delayed by fog and storm, and sea navigation with all its intensive development has not arrived yet at the point where an ocean liner can be brought into harbor in a dense fog and docked.

Up to the present time safety has been secured largely by the long experience and skill of the pilot. One of the greatest changes in the history of piloting however now is taking place as regards the pilot's attitude toward instruments and means of communication and traffic control. A pilot need no longer be without the aid either of instruments or ground personnel during flight.

In order that regularly scheduled flights may be established there are needed:

1. Means for keeping on the course (whether fixed or varied with weather or traffic conditions).
2. Means for checking operating conditions of engines and other equipment.
3. Means for communication enroute as well as at the terminals.
4. Aids for making a safe landing even in fog.

Means for Keeping on the Course

To stay on the course during the most severe weather conditions the pilot must find his way without sight of ground or beacon lights along the airway. Under such conditions he must rely solely upon instruments for direction since his senses then are inadequate and may be dangerously misleading.

For directional indication the pilot must depend upon compass indications. While a small magnetic or card compass fulfils minimum requirements, for accurate and reliable indication the magneto compass has been developed. This instrument is a remote-indicating device utilizing the horizontal component of the earth's field; it is an outgrowth of the earlier earth inductor compass. The generating unit in this instrument is mounted in some part of the plane which is relatively free from distorting magnetic influences, and is driven either by a wind rotor or by an electric motor supplied from the plane's battery. Two permalloy pole pieces are mounted so as to concentrate the earth's field through the armature. Normally the two pole pieces are held in an East-West direction by a course-setting mechanism located within easy reach of the pilot; when in this position no magnetic field is impressed upon the rotating armature. Any change in the direction of flight which will shift the pole pieces from an East-West position brings the permalloy bars under the influence of the horizontal component of the earth's field. Thus a current is generated which shows by means of a conveniently located indicator, deviation to right or left from the determined course. The pole pieces are maintained in a horizontal position by means of a pendulum which is either liquid or air-damped.

All magnetic compasses are subject to errors when accelerations occur which permit the vertical component of the earth's field to influence the sensitive element. To overcome this the turn compensator has been developed. This device employs an electric gyro element, by means of which a potential is impressed upon the magneto compass circuit which bucks the compass potential caused by the acceleration or turn.

In addition to its use as turn compensator, the gyro element may be used independently as turn indicator to aid in maintaining a straight flight. A separate indicator is provided for this use being connected in the same circuit as the turn compensator. A turn indicator obviously is one of the most important instruments

---

From "Electrical Solutions of Problems of Regular Scheduled Flight," (No. 31-M3) to be presented at the A. I. E. E. Pacific Coast convention, Lake Tahoe, Calif., Aug 25-28, 1931.

used in blind flying and accordingly much development work has been done to make it reliable.

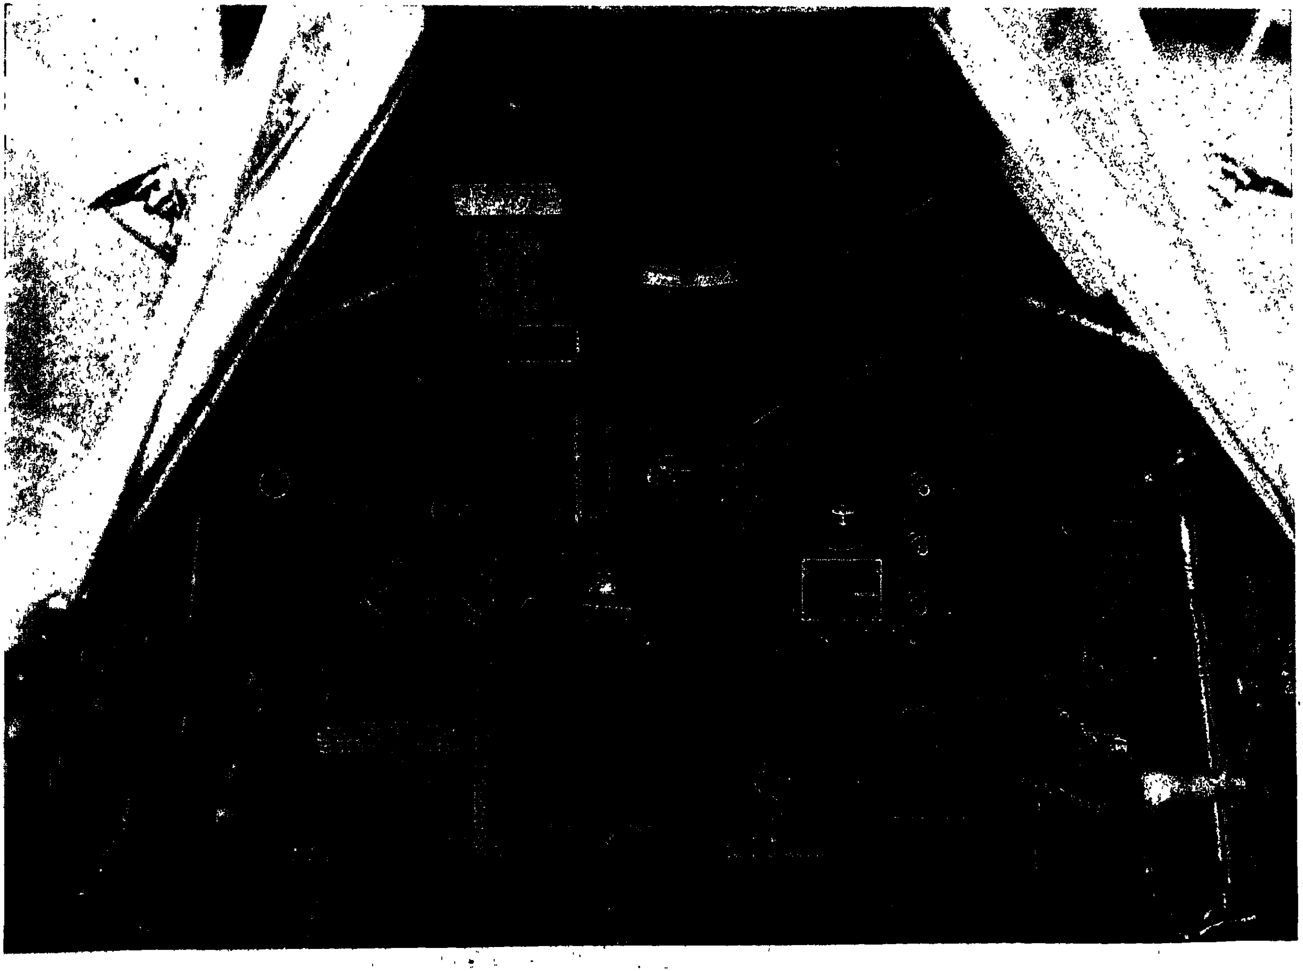
AUTOMATIC CONTROL

Various forms of automatic control have been experimented with for many years, and development is proceeding in all countries to free the pilot from strain and permit him to devote his attention to "avigational" and other matters. One such arrangement has been developed utilizing the magneto compass as the direction-sensitive element and turn compensator as the turn-sensitive element. With this arrangement the magneto compass lays down a definite base line and the turn compensator maintains correct indications during accelerations and turns. A sensitive polarized relay replaces or is used in combination with the compass indicator and through a vacuum-tube circuit, controls two magnetic clutches of an electric steering mechanism. A follow-up system provides for deflection of the rudder from a chosen neutral position proportional to the departure of the craft from the course. The accuracy with which a course may be followed with the aid of this arrangement is remarkably good.

RADIO BEACONS

To be able to fly a straight course blindly is of little advantage, however, unless the aircraft reaches its destination, and no matter how accurate the instruments aboard the plane may be they do not indicate drifting due to winds. Radio has been found useful in this connection in that it furnishes the aviator with reference points or axes. Two general classes of equipment in use are (1) course beacons and (2) direction finding apparatus. In this country the first class is employed almost exclusively along the airways, the two types in general use being respectively aural and visual beacons. The aural type transmits a code signal alternately from two loops thus providing for four courses at each beacon. The listening pilot hears a *dash-dot* or a *dot-dash* signal when off course, depending upon his direction from the course, and a series of long dashes separated by the station's identifying signals when on course.

With the visual type of beacon, the interlocking signal system is replaced by one employing two modulation frequencies which are received with equal intensity when on course and with unequal intensity



Interior view of a typical airplane cockpit showing the multiplicity of instruments to assist the pilot in maintaining safe flight when off the course. While visual indicators employing tuned reeds sometimes are used, pointer-type indicators possessing certain advantages over the reed indicators have been developed.

For flying off the established airways a homing device adaptor has been developed for standard aircraft receivers. This is used with a fixed wing loop and indicates by a meter on the instrument panel whether the plane is on or off course directly toward the station tuned in. Since this device uses the ordinary broadcast wave band as well as that of the beacons, the plane may be directed at any broadcasting station within range; tests have shown that in general a pilot can fly toward a powerful broadcasting station from a distance of about 200 mi.

ALTIMETERS

Among other indications the pilot is vitally concerned in knowing his height above the terrain over which he is flying. Elevation above the starting point is given by a barometric altimeter which is included in the normal equipment of any plane, but inadequate over rough country. The radio altimeter is one of the three general types of instruments which have been developed to solve this difficulty. Operation of this device is based upon the principle that if a radio wave is radiated from an antenna and reflected back to the source by a large, conducting mass, the change in the antenna characteristics will result from the combined outgoing and reflected waves. While this device does not give positive indications at elevations of less than 350 ft., indications of high accuracy may be obtained at altitudes of 650 ft. or more.

MEANS OF CHECKING OPERATING CONDITIONS

Flight and avigation instruments must be supplemented by other instruments showing engine and atmospheric conditions, and general operation of the plane. Here is a wide field for remote electrical indication as multi-motor planes find increased application to transport service. Some of the instruments of this type which have been developed include engine tachometers, oil- and fuel-pressure gages, oil- and water-temperature indicators, and cylinder-temperature indicators. Although recently many different types of these electrical instruments have received publicity, they consist principally of instruments already standardized for other uses, but adapted to meet the special needs of the airplane. The remote indicating features of these instruments make their installation extremely simple as compared with present equipment with its long lengths of tubing and flexible shafting.

MEANS OF COMMUNICATION

A radio beacon may serve to keep a pilot on his course but it does not inform him of conditions along the airway. For this purpose, radio telephone rather than telegraph has been chosen by the majority of transport operators. Now, the pilot under this guidance is in an entirely different situation than a few years ago. Instead of flying into unknown and shifting weather conditions single-handed and without accurate information, he has available many contacts through his own radio equipment. In addition, traffic control at all times during flight has made possible an increase in the safety of landing under conditions of low ceiling and poor visibility.

AIDS FOR LANDING

Safe landing on a fog-bound terminal remains the great problem confronting air transportation. In general, transport companies avoid any possibility of being forced to land in a fog in the same way that all ocean liners meet their corresponding problem. However, organizations now are making strenuous efforts to make safe the blind landing of a plane, and here it is that radio, light, sound, and all other agencies are needed, for each may contribute to the solution. It is through a coordinated system that ultimate success may be hoped for.

Blind landing requires the guidance of the plane from the beacon course, or course determined by direction finding, to an approach course at the airport. In addition, the runway position must be determined; the pilot also must know his height above ground and traffic conditions about the port. Radio plays an important part in directing the plane to the field, in indicating the field boundaries and in providing the pilot with means of communicating with the ground personnel.

Light also furnishes some aid for night flying under conditions of low visibility; however, due to scattering of the light by the fog particles ordinary boundary lighting and floodlighting are of little avail for fog landings. Consequently lighting cannot be considered of much aid under such conditions unless modulated light or intense flashes are available.

SONIC ALTIMETER

For height-above-ground indications in landing, the sonic altimeter is especially adapted. As in depth sounding, sound waves reflected from the ground are utilized. From a compressed-air whistle mounted in a megaphone which directs the signals downward from the aircraft short blasts are blown automatically at brief intervals. The echo of the outgoing signal is received in a second megaphone which is connected through a high-pass acoustical filter to a stethoscope worn by the pilot. A timing device mounted on the instrument panel indicates altitude, this indicator being calibrated directly in feet. As the distance above ground decreases, the interval between the two signals naturally decreases also; experience has shown that when the outgoing signal and echo appear to blend, the plane is at an altitude of about 5 ft. or less.

So varied are conditions under which air transport is carried out that no single arrangement can be said to be best. A system which will fit most satisfactorily into local conditions should be adopted. Whatever method is ultimately used, however, must fulfil the requirements of simplicity, lightness, and reliability.

In conclusion it is quite safe to say that, through the use of sensitive and accurate instruments, safe and regular flights can be established in so far as avigational problems are concerned. Further development work along this line together with the added experience of operators, are hastening the time at which this service will assume a position comparable to other forms of transportation.

Desirable Accuracies in Instrument Transformers

Errors in both the producer's total meter registrations and the consumer's single meterr gistration are analyzed and evaluated by the "probable error" method. Accuracies better than 0.5 per cent are shown to be valueless from a practical standpoint.

By
E. C. WENTZ
Associate A. I. E. E.

Westinghouse Elec. & Mfg. Co., Sharon, Pa.

HOW MUCH SHOULD BE PAID for increased accuracy in instrument transformers? Are power companies seeking accuracies out of proportion to the returns therefrom? Upon these and other important questions related to instrument transformer accuracy the author has attempted to shed some light. As a result of his detailed analysis he has concluded that with normal metering burdens, accuracies better than 0.5 per cent are valueless commercially. It is shown also that accuracies better than 0.5 per cent seldom can be guaranteed, and thus are of no practical value except as they may indicate that the apparatus may be overloaded safely, or that the guarantee has a larger factor of safety.

It is well known that errors in either current or voltage transformers may be decreased by increasing the cross-section of either the copper or the iron. This, however, will inevitably increase the cost of the transformer. The problem then becomes one of analyzing the errors present in the conventional type of instrument transformer and evaluating these from an economic standpoint.

If the transformers in question are used in conjunction with a watthour meter, the aggregate error in meter registration will be due to errors in (1) the voltage transformer, (2) the current transformer, and (3) the watthour meter.

The error introduced by the voltage transformer is usually a constant quantity which can be obtained either by measurement or from a calibration curve. This remains constant so long as the burden and line voltage are constant.

Errors introduced by the current transformer may be shown to vary with the line current (see Fig. 1). This variation may be measured, or obtained from a calibration curve. However, meter registration errors due to the current transformer depend also upon the load cycle and load power factor, as may be noted from Fig. 1. The net effect is that in general the combined errors will be such as to make any meter to which the transformer may be connected, run fast at full current and slow at light currents, although this condition is sometimes reversed at very low-line power factor.

Similar variation exists in the errors introduced by the watthour meter; and the same difficulty will be encountered in estimating the error in total meter registration. A curve showing typical watthour-meter error is given in Fig. 2.

To determine the magnitude of error in total meter registration in terms of the errors in the current transformer and watthour meter is not strictly possible without a vast amount of work involving among other things a record of the load cycle. A relation may be approximated, however, by the introduction of what will be called the "probable error." The idea of a "probable error" is familiar to most engineers, but as used in this particular problem may be defined in the following manner: Each current transformer and each meter introduces an uncertain error into the total watthour-meter registration. This error is uncertain because of its dependence upon the load cycle and other variable factors; its most probable magnitude, however, is designated as the "probable error" and may either add or subtract from the true readings.

An exact determination, or even an estimation of the probable error due to the current transformer, is impossible. However, the probable error will not be greater than the maximum ratio error over the range from 10 to 100 per cent current. This assumption is of course empirical; it is based on the fact that with most current transformers and usual load power

---

Written especially for ELECTRICAL ENGINEERING. Not published in pamphlet form.

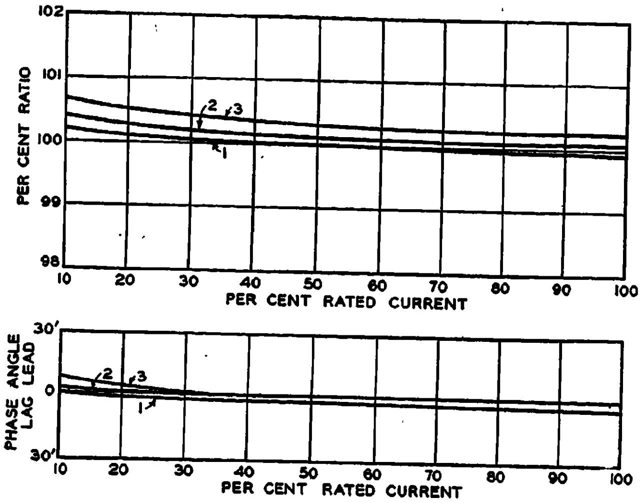


Fig. 1. Ratio and phase-angle curves for typical current transformer

1. 2.5 voltamperes, 0.90 power factor
2. 15 voltamperes, 0.90 power factor
3. 50 voltamperes, 0.50 power factor

factors the maximum error in wattmeter indication does not differ greatly from the maximum transformer-ratio error.

It is conservative to assume the maximum error to be the probable error in registration. Accordingly, this assumption will lead to a pessimistic conclusion, the actual errors being less than predicted by this analysis. This point should be kept in mind following through the rest of the argument.

Probable Error for Producer

A typical three-phase metering installation will involve two current transformers, two voltage transformers, and a watthour meter containing two elements. As already pointed out, the voltage-transformer error usually is constant and may be eliminated.

If the current transformer introduces a probable error of P_1 per cent, and one watthour-meter element an error of P_2 per cent, the total probable error of the combination is $\sqrt{P_1^2 + P_2^2}$ as these errors multiply or divide (see any college physics laboratory manual for combination of probable errors). The error of the combination in the other phase also is $\sqrt{P_1^2 + P_2^2}$. The most probable correct power reading will be the registration of the meter, and the probable aggregate error in this registration will be

$$\sqrt{\frac{P_1^2 + P_2^2}{2}}$$

as the errors in the two phases add or subtract.

In a large power system there will be n such installations, each introducing the same probable error. Therefore the total probable error for the entire system will be

$$\sqrt{\frac{P_1^2 + P_2^2}{2n}}.$$

These expressions indicate the following:

1. It is of little use to reduce one of the errors P_1 or P_2 unless the other is reduced correspondingly. The magnitude of P_1 and P_2 logically should be the same.

2. If n is large enough, the probable error in the individual installation may be objectionably large without causing the probable error in the grand total of all the registrations to be worthy of consideration.

The accuracy of the total registration, which it should be remembered represents the total income of the producer, is insured then by the mere number of meters in a large system, whether or not exceptionally accurate metering apparatus is installed.

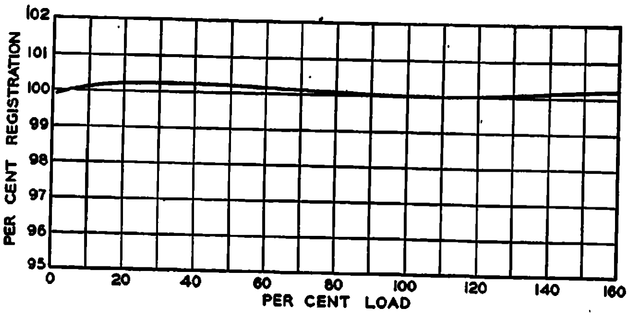

Fig. 2. Load-registration curve for a typical watthour meter

Probable Error for Consumer

To extend the idea of probable error to find the error in the total expenses of a given consumer, it must first be considered that one meter registration generally represents only a small part of any consumer's total expenses. If each of n commodities making up the major part of a consumer's purchased supplies are measured with a probable error of P_1 per cent, the resultant probable error in his total commodity bill will be

$$\sqrt{\frac{P_1}{n}}$$

(assuming the various items to be equal in amount). If one of these individual errors P_1 could be reduced to zero, the probable aggregate error in the bills for the remaining $n - 1$ items would be

$$\sqrt{\frac{P_1}{n-1}},$$

and in per cent of the total bill would be

$$\sqrt{\frac{P_1}{n-1}}\left(\frac{n-1}{n}\right).$$

Reducing one probable error to zero then would reduce the total resultant error from

$$\sqrt{\frac{P_1}{n}} \text{ to } \sqrt{\frac{P_1}{n}}\sqrt{\frac{n-1}{n}}.$$

To reduce the probable error in the measurement of one commodity only, is obviously of negligible benefit. It is evident also that the probable errors in the measurement of the various commodities logically should be the same.

Commodities purchased by weight are weighed on a scale with a probable error of perhaps 0.5 per cent, as the scales ordinarily are used; commodities purchased by volume are measured or metered to within perhaps 0.5 per cent also. It would seem, then, that unless electric power is by far the largest commodity purchased, it will be impractical to meter it to an accuracy better than that attained in the measurement of other commodities supplied.

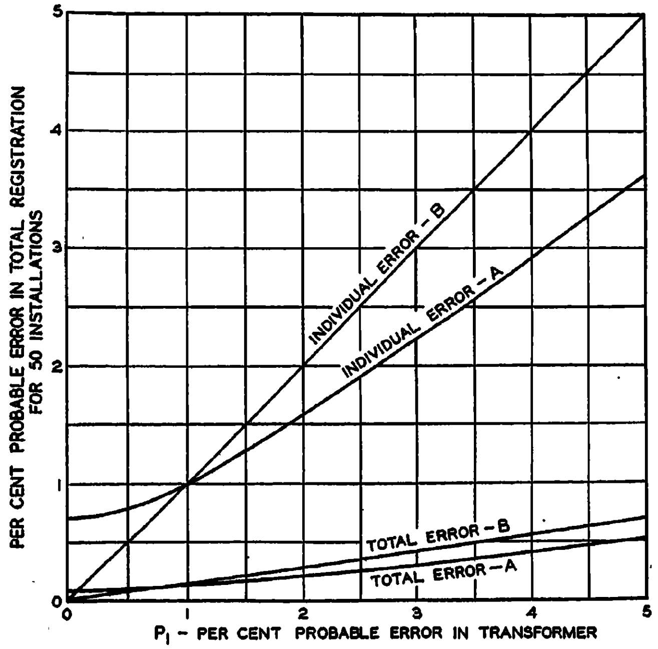

Fig. 3. Probable error in registration for different current-transformer and watthour-meter errors

P_1 = probable error in current transformer

P_2 = probable error in watthour meter element

A. P_2 constant at 1 per cent

B. $P_2 = P_1$

To return to the expressions for probable error in meter registration, and to consider numerical examples:

$$\text{Individual probable error} = \sqrt{\frac{P_1^2 + P_2^2}{2}}$$

$$\text{Total probable error} = \sqrt{\frac{P_1^2 + P_2^2}{2n}}$$

If $P_1 = P_2 = 1$ per cent

and $n = 20$, (a small number).

the probable errors are

$$\sqrt{\frac{P_1^2 + P_2^2}{2}} = 1 \text{ per cent for the individual}$$

$$\sqrt{\frac{P_1^2 + P_2^2}{2n}} = 0.22 \text{ per cent for the total.}$$

If $P_1 = P_2 = 0.5$ per cent and $n = 50$ (a more usual case) the probable error will be 0.5 per cent for the individual but only 0.07 per cent for the total. This aggregate error of 0.07 per cent is within the limits of precision accuracy; still 0.5 per cent represents a reasonable accuracy which may be expected in most cases.

From the foregoing it may be seen that the resultant probable error decreases in the same proportion as do the errors P_1 and P_2. If the probable individual error and the probable total error in meter registration are plotted against P_1, assuming P_2 to remain constant at 1 per cent, curves *A*, Fig. 3 are obtained. If $P_1 = P_2$, curves *B* result as P_1 and P_2 vary together. The curves *A* show that if $P_2 = 1$ per cent, it does little good to reduce P_1 below 1 per cent, since reducing it to zero reduces the total error to only 0.71 per cent.

As a final conclusion it appears a well established fact that no certain advantage is to be expected from more accurate metering apparatus than now is available. That accuracy better than 0.5 per cent in a meter or current transformer is of no commercial advantage has been amply demonstrated. Furthermore, this conclusion is supported by the fact that current transformer errors cannot be measured with present commercial testing apparatus with much better accuracy than 0.1 per cent in ratio and 5 min. in phase angle. Consequently, attempts to meet accuracies of better than 0.5 per cent generally result in arguments which never are settled satisfactorily.

Konel—

A Substitute for Platinum

A MAN set out to find a cheap substitute for platinum. He was so successful that for almost a year his results were not taken seriously.

Oxide-coated filament for radio tubes was known as early as 1904; platinum as a core appeared to be the best material for life, strength, and emission of electrons.

From *Research Narratives*, May 15, 1931, published by the Engineering Foundation, 29 W. 39th Street, New York, N. Y. Based on information supplied by Erwin Foster Lowry, Ph. D., research physicist, Westinghouse research laboratory, East Pittsburgh, Pennsylvania.

In 1925, five years after radio broadcasting had aroused public imagination, tubes were being made in ever-increasing quantities with platinum or platinum-iridium core filament. Platinum people were overjoyed, but not makers of tubes. Material for filaments was costing $186 an ounce.

Dr. E. F. Lowry, research physicist of the Westinghouse research laboratory, undertook a search for a cheaper substitute. Iron, nickel, nichrome, tungsten, various ferrous alloys already were pronounced worthless. All had a poisonous effect on emission or had proved mechanically weak. But nickel looked good to Lowry in spite of its reputed mechanical frailty.

The first filament of pure nickel gave surprising results. Emission appeared to be as good as with platinum cores; no more trouble arose from mechanical failures. Scientists, tube manufacturers, even colleagues, hesitated to believe that the first attempt had succeeded when hitherto undisputed authority had pronounced nickel no better than other metals. Against claims that nickel filaments should have a life of only 80 hr., Lowry produced tubes on life tests for 1,500 hr. and still burning. But none of his nickel filaments were manufactured commercially.

Convinced that he was working in the right direction he tried 20 per cent cobalt; the crystalline structure was unsatisfactory and could not be drawn. The case looked hopeless when he thought of the qualities of cobalt-ferrotitanium (a compound of iron and titanium) wire used in experiments several years previously. The first filament of nickel, cobalt, and ferrotitanium, in proportion of 80, 20, and 10, gave results better than ever before. Hundreds of experiments have since been made, but the alloy used today is essentially the same as that produced by Lowry's first attempt.

He named the new metal "konel," and in December 1926 persuaded the Westinghouse Lamp Company to make 50 commercial tubes with it as filament core. About the same time, the manufacturers discovered that Lowry was right also about nickel and started to use that for filaments. Within a year every manufacturer ceased the use of platinum in radio tubes, and none has used it since. Platinum-iridium cost $1,600 per lb.; konel costs a few dollars.

Use of konel not only appreciably increased tube life (operating 175 deg. colder than platinum filament), but also showed definitely that the filament core had a marked influence on emission. A new theory of electron emission from oxide filaments has been formulated; on this work the discoverer is now engaged.

Konel is harder to forge than high-speed steel and is very tough at high temperatures, when most metals lose their strength. It is extremely resistant to most acids, does not sputter, does not scale like iron under heat, and has a high electrical resistance. These unusual characteristics give promise of many uses outside radio tubes. It is an electric furnace product of extreme purity.

Mutual Impedance of Grounded Wires

A formula is given for the mutual impedance between two insulated wires of negligible diameter lying on the surface of the earth and grounded at their end-points.

By
R. M. FOSTER
Member A. I. E. E.

American Tel. & Tel. Co., New York

WE ASSUME the earth to be flat, semi-infinite in extent, of unit permeability, of negligible dielectric constant, and of uniform conductivity λ, using c. g. s. electromagnetic units. The air is also assumed to be of unit permeability and of negligible dielectric constant. All displacement currents are thus neglected both in the earth and in the air. This is the assumption which is ordinarily made as a first approximation at power frequencies for the shorter transmission lines.

The mutual impedance between circuits consisting of insulated wires of negligible diameter lying on the surface of the earth and grounded at their end-points is then found to be

$$Z_{12} = \frac{1}{2\pi\lambda}\int\int\left\{\frac{d^2}{d\,S\,d\,s}\left(\frac{1}{r}\right) + \frac{\cos\epsilon}{r^3}\left[1-(1+\gamma r)\,e^{-\gamma r}\right]\right\}d\,S\,d\,s \quad (1)$$

The integrations are extended over the two wires S and s, their elements $d\,S$ and $d\,s$ being separated by the distance r and making the angle ϵ with each other. In this formula $\gamma = (i\,4\,\pi\,\lambda\,\omega)^{1/2}$ is the propagation constant in the earth for plane waves which vary with the time as $e^{i\omega t}$, where $\omega = 2\,\pi$ times the frequency and $i = (-1)^{1/2}$.

This mutual impedance formula (1) may be written in the equivalent form

$$Z_{12} = \int\int\left[\frac{1}{2\pi\lambda}\cdot\frac{d^2}{d\,S\,d\,s}\left(\frac{1}{r}\right) + i\omega\frac{\cos\epsilon}{r}\left\{\frac{2}{(\gamma r)^2}\left[1-(1+\gamma r)e^{-\gamma r}\right]\right\}\right]d\,S\,d\,s \quad (2)$$

The complex factor

$$\frac{2}{(\gamma r)^2}\left[1-(1+\gamma r)\,e^{-\gamma r}\right] \quad (3)$$

From "Mutual Impedance of Grounded Wires Lying on the Surface of the Earth," *Bell System Technical Journal*, July 1931.

approaches unity as ω approaches zero, and Z_{12} then agrees with the d-c. mutual impedance as given by G. A. Campbell.[1] Introducing this factor (which is a function of γr only) into the reactance term for the d-c. mutual impedance between two elements dS and ds gives the general expression for their mutual impedance corresponding to the propagation constant γ. The variation of the complex factor (3) for increasing values of γr is shown very clearly in the figure, where the real and imaginary parts of (3) are plotted for increasing values of $r' = |\gamma r| = (4\pi\lambda\omega)^{1/2} r$. The real part, it may be noted decreases rapidly from the initial value unity as r' increases, while the imaginary part is always negative, decreasing from zero to a minimum value (approximately -0.3 for $r' \doteq 1.5$) and then increasing towards zero, although it does not approach zero so rapidly as does the real part.

The first three terms in the expansion of Z_{12} for low frequencies are given by

$$Z_{12} = \frac{1}{2\pi\lambda}\left(\frac{1}{Aa} - \frac{1}{Ab} - \frac{1}{Ba} + \frac{1}{Bb}\right) + i\omega N_{Ss} + (1-i)\frac{1}{3}(8\pi\lambda\omega^3)^{1/2} A\,B\,a\,b\cos\theta + \dots, \qquad (4)$$

where N_{Ss} is the mutual Neumann integral between the two wires S and s of arbitrary form but with end-points A, B and a, b respectively; θ is the angle between the straight lines $A\,B$ and $a\,b$. The first two terms in this expansion are precisely the d-c. mutual impedance as given by G. A. Campbell.

The first term in the expansion of Z_{12} for a long straight wire S and any wire s located near the midpoint of S is

$$\int\left[\frac{1}{\pi\lambda x^2} - \frac{\gamma}{\pi\lambda x}K_1(\gamma x\cdot\right]\cos\epsilon\,ds, \qquad (5)$$

x being the positive distance from ds to S, and ϵ the angle between ds and S.

$$K_1(z) = -\frac{1}{2}\pi H_1^{(1)}(iz)$$

is the Bessel function of the second kind for imaginary argument as defined by G. N. Watson.[2]

The expression in square brackets in (5) is the mutual-impedance gradient, parallel to an infinite wire at a positive distance x from the wire. It agrees with the results published independently by F. Pollaczek,[3] J. R. Carson,[4] and G. Haberland,[5] and has been employed to obtain numerical results since 1917. Pollaczek has also investigated the case of two grounded circuits of finite length.[6]

The mutual impedance dZ_{12} between a short, grounded circuit dS and a counterclockwise small loop of area da, on the surface of the earth, may be found by applying Stoke's theorem to formula (1), obtaining

$$dZ_{12} = \frac{dS\,da}{2\pi\lambda}\cdot\frac{\sin\phi}{r^4}\left[3 - (3 + 3\gamma r + \gamma^2 r^2)e^{-\gamma r}\right], \qquad (6)$$

where ϕ is the angle which dS makes with r, the line from da to dS.

By a further application of Stoke's theorem we may obtain the mutual impedance between two counterclockwise small loops dA and da; namely,

$$dZ_{12} = \frac{dA\,da}{2\pi\lambda}\cdot\frac{1}{r^5}\left[(9 + 9\gamma r + 4\gamma^2 r^2 + \gamma^3 r^3)e^{-\gamma r} - 9\right]. \qquad (7)$$

Burn-Off Tests in Low-Voltage Networks

By
GEORGE SUTHERLAND and D. S. MacCORKLE
Fellow A. I. E. E. Associate A. I. E. E.
New York & Queens Elec. Lt. & Pwr. Co., Flushing, N. Y.

An extensive series of tests on standard and experimental cables installed in accordance with standard accepted practise for a-c. low-voltage underground networks, are outlined in this article. Results obtained are useful not only in determining mains-conductor size and network-transformer spacing, but also for indicating desirable future developments in cables for this service.

Fault in single-conductor buried cables cleared in 40 sec. at initial location; total current—5,800 amperes

IT IS RECOGNIZED generally that one of the most essential requirements to be met in the operation of a-c. low-voltage networks is the ability of the system to burn faults clear in the underground cables automatically. The purpose of the present study was to determine the characteristics of fault clearance in such networks, tests having been made on both standard and experimental cables.

Faults in cables may be classified with respect to their ability to dissipate the heat generated as, (1) a fault having a thermal capacity less than that of the cable conductors, and (2) a fault having a thermal capacity greater than that of the cable conductors. The clearance of a fault of the first class depends therefore upon the destruction of the fault itself or a progression of the fault and the subsequent burning clear of the cable conductors at a location remote from that of the initial fault; the clearance of a fault of the second class depends upon the fusing of the cable conductors joining the fault.

Nearly all operating experience in low-voltage a-c. network systems has been with rubber- or paper-insulated lead-covered cables. Both operating and previous test data have shown that all ground faults between the conductor and lead sheath have cleared. Tests made (*Low-Voltage A-C. Networks of the Standard Gas and Electric Company's Properties*, by R. M. Stanley and C. T. Sinclair, A. I. E. E. Trans., Vol. 49, p. 278) have indicated also that a minimum of 5,000 amperes is required to clear faults in 500,000-cir. mil cables and a minimum of 3,500 amperes to clear faults in 250,000-cir. mil cables.

Equipment and Tests

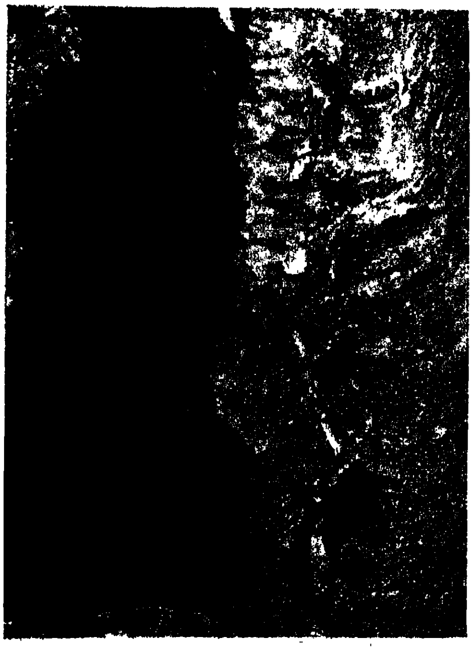
The test set-up consisted of 4,000/230-volt network transformers, current-limiting devices, and instruments for voltage and current indications. The transformers were supplied with 60-cycle power from an isolated substation bus section, and were connected so that a 900-kva. capacity supplied power to each side of the fault in the test cable connected in the low-voltage circuit. Both experimental and standard cables were installed

---

From "Burn-Off Characteristics of A-C. Low-Voltage Network Cables," (**No. 31-66**) presented at the Middle Eastern District meeting of the A. I. E. E., Pittsburgh, Pa., March 11-13, 1931.

for test under conditions simulating present underground-network constructions. A total of 86 burn-off tests was made. Two types of multiple-conductor buried non-magnetic sheath cables were tested, each cable containing three No. 4/0 phase conductors, one No. 2/0 neutral conductor, and one No. 6 conductor which would be required in an actual system layout for multiple street lights. Tests were made also on eight types of single-conductor No. 4/0 buried non-magnetic-sheath cables; four types of No. 4/0 non-metallic-sheath cables for duct installation; and one each of No. 4/0 rubber-insulated, 350,000-cir. mil and 500,000-cir. mil paper-insulated lead-covered cables. In addition to these, two tests were made on No. 4/0 bare conductors, spaced and buried in relatively dry soil.

In general, the tests included a wide variety of faults, the insulation and coverings of the cable in most cases being stripped for a length of approximately six inches from the conductors to be short-circuited; the conductors were then forced together for a length of about three inches and bound in that position with friction tape. In some of the tests on multiple-conductor buried cables a large iron clamp was used to force the conductors together. Several investigations were made also on copper-to-copper and copper-to-ground faults of the point-contact class.



Remains of single-conductor non-magnetic-sheath cables and ducts after test

(Left) total current—0 to 5,000 amperes for 11.5 min.; (right) total current — 0 to 3,600 amperes for 21.5 min.

CONCLUSIONS

Results of these tests, together with other information obtained from operating data and previous publications, are summarized in the following general conclusions:

1. Point-contact and conductor-to-sheath faults.

Faults of this type occurring in single-conductor lead-covered cables in 120/208-volt networks usually were cleared within a period of several seconds irrespective of conductor size where the minimum current available was approximately 3,000 amperes.

2. Copper-to-copper faults.

These faults, made as described by taping the bared conductors together for a length of about three inches, will clear at the fault location within one minute's time (usually less) provided certain minimum values of short-circuit current (see accompanying table) are maintained during the entire short-circuit period.

MINIMUM SHORT-CIRCUIT CURRENT FOR CLEARING COPPER-TO-COPPER FAULTS IN SINGLE-CONDUCTOR CABLES

	Short-circuit current in amperes	
Conductor size	Per conductor	Total
No. 4/0	3,000	6,000
350,000 cir. mils	4,000	8,000
500,000 cir. mils	5,000	10,000

3. Faults in buried cables.

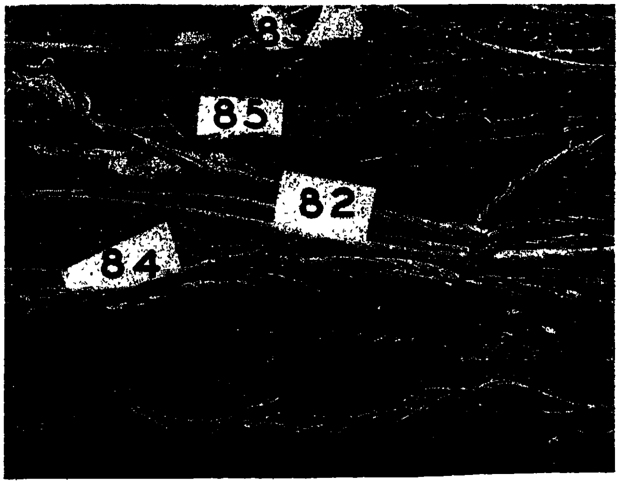
Buried single-conductor non-magnetic-sheath cables when dropped into the trench at random possess approximately the same general burn-off characteristics as do single-conductor cables installed in four-inch non-metallic ducts. These characteristics are improved somewhat by separating the cables.

4. Faults in buried multiple-conductor cables.

Burn-off characteristics of this type of cable with non-magnetic sheath makes it undesirable for low-voltage a-c. network distribution. The better burn-off characteristics of buried single-conductor cables are attributed largely to a wider separation of the conductors, and coverings impregnated with a flameproof compound.

5. Oiled paper *vs.* rubber insulation for buried cables.

In the matter of burn-off characteristics vulcanized sulfinated oiled-paper insulation appears to offer no improvement over ordinary rubber insula-



500,000-cir. mil paper-insulated lead-covered cables removed from ducts after test

Note cables of test No. 83 in which a total current of 10,400 amperes cleared 3-in. contact fault in 1.25 min. Initial current for the remaining cables was from 7,300 to 9,000 amperes tions. Analyses show no appreciable difference in the explosibility and inflammability of gases produced with either type of insulation on lead-covered cables.

6. Time required for fusing.

Assuming current values to be constant calculated values of fusing time are sufficiently accurate for all practical purposes provided total arcing time does not exceed approximately eight minutes.

7. Gases liberated during fault period.

With either oiled-paper or rubber insulation, explosions may occur due to gases liberated by arcing faults in underground cables if these faults persist for more than five minutes.

Analyses of these gases indicate that approximately 50 per cent of the gaseous mixture is combustible; and laboratory tests show that the gases from both types of insulation contain in general the same constituents and are evolved in the same relative quantities. Gases emanating from the burning of fiber duct now used in underground systems do not appear to affect the combustibility of the gaseous mixture from an arcing fault.

As stated, the foregoing conclusions are based upon operating data and results of the tests outlined in this article which were made upon cables buried in both relatively dry and in relatively wet soil, and others installed in relatively dry ducts. In addition to the conclusions already outlined the tests indicate certain other burn-off characteristics desirable in cables for use in a-c. low-voltage underground networks. Development of new insulating materials to provide these cables with such characteristics will require further research and experimentation.

Transient Voltages in Auto-Transformers

Effects of transient voltage phenomena upon auto-transformer design are discussed briefly. Results given are based upon tests.

By
K. K. PALUEFF General Elec. Co.,
Member A. I. E. E. Pittsfield, Mass.

GENERAL PRINCIPLES controlling the high-frequency voltage phenomena within auto-transformer windings are the same as those governing such phenomena in ordinary transformer windings. Since these principles have been discussed previously (A. I. E. E. TRANS., Vol. 38, p. 477; Vol. 48, p. 681; Vol. 48, p. 998; and Vol. 49, p. 1179) this should be looked upon as a continuation of that discussion and as written on the assumption that the reader is thoroughly familiar with the papers mentioned in those references.

To clarify the terms used, it should be noted that here:

1. The transmission line that brings a given surge to an auto-transformer is called the "primary line," while the other line of the auto-transformer is called the "secondary line."

2. The transmission line connected to the highest point of the auto-transformer winding is termed the "high-voltage line," while the line connected to the intermediate point is termed the "low-voltage line."

3. Part of the winding between the high-voltage and low-voltage lines is called the series winding, and the remaining part between the low-voltage line and ground is called the common winding.

ORDINARY AUTO-TRANSFORMER

In an auto-transformer two points of the winding are connected to transmission lines and it is this feature that makes the oscillation of an auto-transformer winding essentially different from that of an ordinary transformer winding. Because of the two independent transmission lines connected to the same winding, four different conditions of surge excitation are possible:

1. Surge arrives from high-voltage line.
2. Surge arrives from low-voltage line.
3. Two surges of the same polarity arrive simultaneously, one from each line.
4. Two surges of opposite polarity arrive simultaneously, one from each line.

The first two cases are the most common; the last two are rare because they may occur in two cases only, (1) when the lines are parallel and (2) when the lightning storm takes place directly over the auto-transformer.

SURGE FROM HIGH-VOLTAGE LINE

It is obvious that when a surge arrives from the high-voltage line the voltage distribution throughout the winding will be influenced by the potential rise of the low-voltage line arising from the surge transmitted through the auto-transformer windings. The magnitude and wave shape of the voltage rise of the secondary line depend upon (1) the shape of the incident wave, (2) the surge impedances of primary and secondary lines, (3) the effective inductance and turn ratio of the auto-transformer, and (4) the length of the secondary line. In most practical cases the rise of potential of the secondary line is slow as compared with the internal oscillation of the auto-transformer windings. Because of the finite length of the incident wave, and the rela-

---

From "Effect of Transient Voltages on Power Transformers—III—Non-Resonating Auto-Transformers," (No. 31-41) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

tion of the surge impedances and inductances found in practise, the ultimate potential of the secondary line is found to be a small fraction of the crest value of the incident wave of the primary line.

For these reasons the phenomena of oscillation of the series winding can be divided conveniently into two parts, (1) the rapid internal oscillations and (2) the relatively slow potential rise of the secondary line terminal. This permits the assumption that in most cases found in practise the secondary line acts as a solid ground for the internal oscillations produced in the windings by lightning disturbances originating on the primary line. Thus it may be said that the part of the winding between the terminals of the two lines oscillates as if the secondary terminal were solidly grounded. The part of the winding between the secondary terminal and neutral oscillates practically as a short-circuited secondary winding of a transformer, while the secondary terminal potential rises above ground at a substantially lower rate.

Practically full voltage of the incident wave appears across the series winding. In case the series winding has substantially fewer turns than the common winding, appreciable internal overvoltage may be created in the common winding by the step-up action due to mutual inductance between series and common windings. This fact is responsible also for the appearance of much higher voltages between turns of the series winding than would be found in transformer windings of the same voltage rating, or in the same auto-transformer with the low-voltage line disconnected. It follows that both of the effects mentioned may be particularly prominent in auto-transformers interconnecting transmission lines of closely similar operating voltages. The foregoing phenomena are characteristic of all auto-transformers.

Both amplitude and shape of secondary-line wave for any shape of incident wave on the primary line may be computed theoretically. Experimental study with different shapes of incident wave has confirmed the calculated results very satisfactorily.

With engineering accuracy it may be stated that, to the greatest part of the lightning wave as transmitted from the primary to the secondary line, an auto-transformer acts as an ordinary inductance connected between the two lines. The value of this inductance may be found by dividing the ohmic short-circuit reactance of the auto-transformer obtained at operating frequency, by 6.28 times the operating frequency.

SURGE FROM LOW-VOLTAGE LINE

In this case an incident wave strikes the series and common windings simultaneously at their point of contact. Since the other end of the common winding is grounded permanently, and that of the series winding is connected to a transmission line, the oscillations of both windings are similar. This similarity, however, disappears in case of a substantial difference in the number of turns in the series and common windings. This happens because of the prominence in such a case of the step-up action referred to before.

SIMULTANEOUS SURGES

Cases of simultaneous surges are very rare; therefore no space will be devoted to their discussion here.

In case the high-voltage line is disconnected, an incident wave from the low-voltage line will cause the common winding to oscillate as a solidly grounded winding, and the series winding to oscillate as a winding completely isolated from ground, as was described in previous Institute papers. In case the low-voltage line is disconnected and the incident wave arrives from the

high-voltage line, the entire winding oscillates as an ordinary transformer winding with solidly grounded neutral.

NON-RESONATING AUTO-TRANSFORMER

To reduce the danger associated with internal voltage oscillations, which cause abnormally high concentration of local stresses, a non-resonating auto-transformer has been developed and applied to practise. Tests have shown that it gives substantially uniform transient-voltage distribution. Underlying principles governing the construction are very similar to those which apply for non-resonating transformers.

The presence of two transmission lines connected to two different points of the winding causes some modification in the proportioning and distribution of shields as compared with that in a non-resonating transformer. In general appearance and construction, however, the non-resonating auto-transformer is very similar to the ordinary non-resonating transformer.

It is the author's opinion that the non-resonating auto-transformer is particularly well adapted to the concentric construction of windings typical of core-type transformers. Its windings are uniform mechanically as well as electrically, and free of the points of discontinuity and breaks which are characteristic features of interleaved windings. These breaks are points of extremely high voltage concentration. In spite of this fact, however, their dielectric strength often is made proportional to the test voltage produced across them during standard A. I. E. E. induced-voltage tests. Such grading of major insulation, of course, is not justified because in an ordinary auto-transformer, as contrasted to the non-resonating auto-transformer, the distribution of transient-voltage stresses does not correspond to the distribution of stresses created by standard low-frequency tests.

CONCLUSIONS

Ordinary Auto-Transformer

1. With only one transmission line connected to an auto-transformer, a traveling wave produces internal oscillations similar to those produced in an ordinary transformer.

2. With both transmission lines connected to their respective terminals, a traveling wave impressed from one line creates two kinds of voltage transients in the windings; the first is relatively slow and responsible for the rise of potential on the secondary line; the second is relatively fast and consists of internal free oscillations in the windings.

3. For the internal free oscillation, a secondary line of sufficient length acts in most cases as a solid ground.

4. Internal stresses, particularly those between turns, are higher in an auto-transformer than in an ordinary transformer of the same voltage rating. This condition becomes aggravated as the auto-transformer voltage ratio approaches unity.

Non-Resonating Auto-Transformer

1. Auto-transformers can be built which are non-resonating for usual conditions of operation.

2. The windings of non-resonating auto-transformers are uniform and free of breaks.

3. Non-resonating auto-transformers are similar to ordinary non-resonating transformers in general appearance and construction.

An Improved Welding Generator

A neutralizing d-c. transformer removes troublesome transients from current output of welding generator.

By
J. H. BLANKENBUEHLER

Westinghouse Elec. & Mfg.
Co., East Pittsburgh, Pa.

TROUBLES most commonly experienced with welding generators of inferior characteristic are (1) fusion of the electrode solidly to the parent metal upon contact and (2) frequent extinction of the arc by slight disturbances.

When contact is made between a new electrode and a cold plate neither should be melted until an arc is drawn; however, if the contact resistance and instantaneous short-circuit current are sufficiently high immediate fusion at the contact point will occur.

From "An Improved Arc-Welding Generator," (No. 31-13) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

Family of curves for a 7.5-kw., 25-volt, 1,750-r.p.m. separately-excited differentially-compounded arc-welding generator

Fig. 1. Output current curves for typical arc-welding generators

With the resistance thereby reduced, the molten spot solidifies and the electrode is "frozen." To obviate this difficulty it is necessary for a generator to have not only a low ratio of short-circuit current to welding current, but also to have no momentary current rise above the stable short-circuit value.

The operator's other annoyance, arc instability, is explained by the fact that in any particular arc there probably is a minimum value of current below which the arc will become extinguished. The actual value of such minimum current is dependent upon arc length, size and material of electrode and welded object, magnetic conditions about the arc, presence of flux or stabilizing gases, velocity of air blowing on the arc, and many other factors. Assuming this minimum current to exist, it can be said that any disturbance at the arc, which reacts on the generator so as to allow the current to drop below the minimum stable arc value, will extinguish the arc. To obviate this difficulty, then, it is apparent that the generator must accommodate changes arising from instantaneous variations in load (arc) resistance without permitting the delivered current to drop even momentarily below the minimum stable value.

Natural reactance within the welding circuit tends to overcome both difficulties by smoothing the welding current, and the addition of sufficient reactance to the circuit of course would approximate the desired results. An adequate reactance, however, would be large and prohibitive in power loss.

Practical experience, extensive tests, and numerous

oscillographic records show conclusively that a generator having the short-circuit characteristics shown by curve B in Fig. 1 (left) and the arc-lengthening characteristics of curve B in Fig. 1 (center) produces a flexible and easily managed arc. The approximate constant-current volt-ampere characteristic best suited to a single-operator welding generator can be obtained most efficiently with a separately-excited differentially-compounded machine. Because of the current in the series field the voltage of this type of generator naturally follows the arc voltage for any given shunt-field current as a result of the inverse action of the series field. Typical curves are given in Fig. 1 (right). As previously implied, however, in addition to the ultimate steady-state condition it is imperative that the response be practically instantaneous in order to obviate the undesirable transients. In the ordinary design such rapidity of response is impossible because of the effects of magnetomotive force interlinkage among generator coils and the resulting transformer action. This delaying effect is demonstrated by the surge of curves A of Fig. 1 (left and center). Elimination of the surges requires that by the time the current builds up to its final value, the flux shall have changed to its final value.

Magnetomotive forces produced by currents induced in every conductor linking the flux retard the requisite change. Extensive tests have shown, however, that from a practical standpoint only the hindering effects developed within the field coils themselves are of sufficient magnitude to be important. Thus the problem reduces to that of preventing the development of undesired induced counter electromotive force within the field coils, or of neutralizing its effect by introducing into the field circuit an opposing voltage approximately equal at every moment to the instantaneous induced voltage.

The logical method of producing the required neutralizing voltage is to use a transformer with its primary in the welding circuit and its secondary in the field circuit as shown in Fig. 2. With the series field and the transformer primary in series, and hence carrying identical currents, any change in current will affect both at the same instant and the transformer secondary voltage will neutralize any voltage induced into the field coils as a result of the change.

Another feature of the system lies in the fact that by the proper proportioning of transformer primary and secondary the field current can be changed to induce a magnetomotive force which will promote the desired flux change; this force can be used to offset any retarding forces arising outside of the field coils. The device is equally effective in neutralizing the retarding effect of the field coils on any type of welding generator whether separately- or self-excited.

In addition to the ease of striking and maintaining a satisfactory arc with the described device, tests show a greatly decreased porosity of weld and improved efficiency in metal deposit.

A Telegraph Testing Machine

Telegraph line efficiencies and signal distortion measurements are only two of th many uses for this unique device. By means of an unusual electrochemical recorder, time intervals of one ten-thousandth of a second in the opening and closing of electrical circuits are graphically recorded.

By
F. B. BRAMHALL
Associate A. I. E. E.

Western Union Telegraph Co. New York

ANY MEASUREMENT of the quality of telegraph transmission is of necessity a measurement of the extent to which the received signaling pulses are distorted from the form in which they were originally transmitted. For the purpose of this article, signal distortion will be defined as the deviation in length and time relationship of the received signal pulses, from the absolute length and time relation of their transmission. This definition confines the measurement of distortion to the measurement of the time relationships which obtain between the signaling pulses as repeated by a relay or other repeating instrument. The unique arrangement of the electrochemical recorder of the transmission testing machine adapts it especially to the measurement of these time relationships.

A conception of the principle of the machine can be formed most readily if it first be considered as arranged for local testing of circuits both ends of which are available at the test point. Referring to Fig. 1, the commutator transmits signals to the circuit or apparatus under test. These signals operate a relay at the receiving end of the test circuit; the relay contacts control the potential applied between a metallic marking needle carried on an arm on the revolving shaft of the machine, and a metallic platen over which a saturated electrochemical recording tape passes. The arm which carries the marking needle revolves on the same shaft with the transmitting brushes, the revolving metallic marking needle making a light contact with the surface of the saturated paper tape. The chemical solution with which the tape is moistened and the material of the

marking needle are such that when the proper polarity of potential is applied to the needle a deep blue mark results from the electrochemical action. If in response to a transmitted signal pulse, the receiving relay energizes the marking needle during the time of its transit across the recording paper, a mark is made continuously until the needle is again deenergized at the termination of that pulse. Thus if transmission over the circuit under test be perfect, the revolving needle draws a line on the paper tape which is a true projection of the arc of the transmitting segment of the commutator. The recording tape moves at a slow rate; just sufficient to separate slightly the succeeding recorded marks.

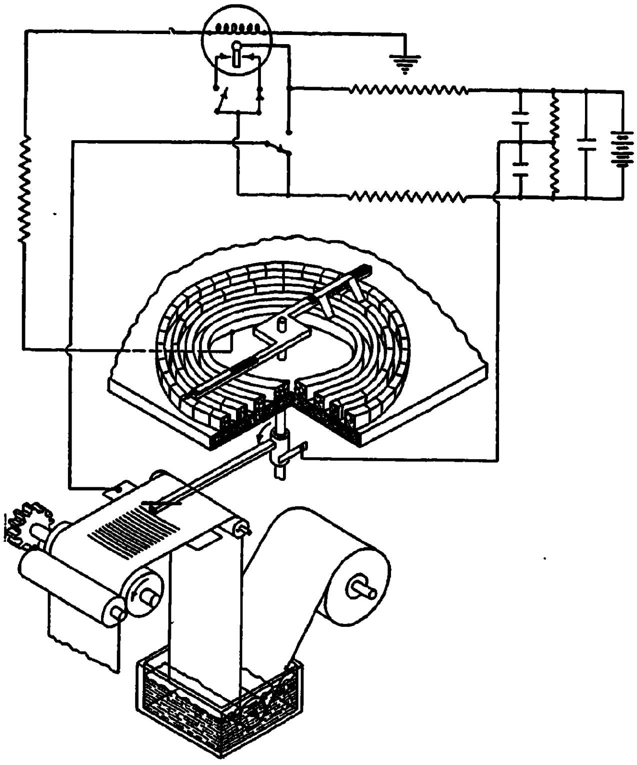

Fig. 1. Details of chemical recording mechanism. Note that recorder needle and commutator arm are mounted on the same shaft

Transmission and reception of signals by a common rotating member is obviously not essential in this method of measuring but may be performed by separate rotating members so long as proper synchronism of rotation is maintained. It is through the use of carefully synchronized transmission and reception that point-to-point testing is done.

In transmission measurement work of any kind it is common to use selected combinations of test signal pulses, either such combinations as represent certain letters in the signaling code or perhaps those which experience has shown are most susceptible to "fortuitous" and "characteristic" distortions. Fortuitous distortion is the shortening or lengthening of signal pulses which results from extraneous disturbing currents in the signaling circuit or from irregular and improper functioning of receiving or repeating instruments. Characteristic distortion is the shortening or lengthening of signal pulses, which is governed by the sequence of the pulses themselves and by the electrical and magnetic characteristics of the signaling circuits and apparatus.

For convenience, the transmission testing machine is equipped with a multi-point rotary switch which quickly sets up on the transmitting commutator any one of a number of predetermined test signal combinations.

Uses of the transmission testing machine in the analysis of signal distortions are most conveniently explained with the aid of sample records. Reproductions of typical records are shown in Figs. 2 to 5. In the more common classes of measuring work two test records are obtained, one showing the repetition from either contact of the receiving instrument. Through comparison of the two, bias of signals is either eliminated or quantitatively determined. Only one record is reproduced here in each case.

local circuit is shown in Fig. 2. At the bottom of this record is shown a short section made with the recording circuit so arranged that the marks are continuous except for the time that the relay tongue is not in contact with either of its stops. In this portion of the record the length of the breaks in the traces made by the recording needle is proportional to the "transit time" of the relay armature.

Typical performance of a poorer repeating relay is shown in Fig. 3. This record illustrates both a "transit time" loss and the loss due to the rebound or "chatter" of the tongue contact against its stop. A common form of characteristic distortion (that caused by a sluggish circuit or instrument) is shown in Fig. 4 together with a typical example of fortuitous distortion caused by a line disturbance. The periodic nature of this disturbance is evident in the regular beats produced in the received signals.

Records of over-all transmission in straightaway and field testing work are made by arranging the recording circuits so that the only traces made by the recording needle are those representing the open-circuit time of the receiving-relay contacts. These "negative" records convey the same information as do those of the other type and in this class of testing are generally preferred. They are desirable particularly where the test pulse combinations are of the nature of "traffic" signals.

The transmission testing machine finds a wide field of usefulness both in the measurement of over-all transmission efficiencies and in the analysis of transmission losses. It may be used as a monitoring recorder to check the distortion of "traffic" signals at either repeater or terminal points. Obviously it is not limited to the polar, two-element, class of signal work chosen for the explanation. It is as readily used for work on ocean-cable circuits employing a three-element code, and on neutral Morse or carrier circuits.

Average-Voltage Method for Transformer-Loss Measurement

By
ARAM BOYAJIAN
Fellow, A. I. E. E.
General Electric Co.
Pittsfield, Mass.

IN THE LATEST issue of the A. I. E. E. STANDARDS (May, 1930), Sec. 13, Par. 13-306, the following appears:

> "The no-load loss of transformers shall be determined preferably with a sine wave of applied voltage; if this is not practicable, the results obtained with a distorted wave of applied voltage shall be corrected to a sine-wave basis." And, foot-note: "For correcting to the sine-wave basis, method based on the measurement of average voltage is recommended."

The reason and basis for the adoption of this rule and recommendation by the A. I. E. E. is explained in the following discussion.

Unlike its load loss, the no-load loss of a transformer is very sensitive to wave shape and different test-voltage wave shapes cause radically different values to be obtained in its measurement. Therefore the no-load loss guarantee on a transformer means little unless the test result is reduced to a sine-wave basis.

Most of the no-load loss in a transformer is hysteresis loss. This is not a function of the *effective value* of the flux density or voltage, but is a function of the peak value of the flux density, which in turn is proportional to the arithmetic *average value* of the voltage. Peaked-voltage waves produce flat-topped flux waves and low-hysteresis loss, whereas flat-topped voltage waves produce peaked-flux waves and high-hysteresis loss. In commercial tests, the voltages usually become peaked and may lead to measurements which often are 10 and occasionally as much as 50 per cent too low. A no-load sine-wave voltage of a generator is no assurance of reliable results, because the distorted exciting current of the transformer under test usually materially distorts the terminal-voltage wave of the generator.

The amount of distortion caused by the transformer exciting current is roughly a function of the ratio of the transformer kva. rating to the generator kva. rating. Other factors that enter in are the percentage synchronous reactance of the generator, percentage field excitation of the generator, and the flux density of the transformer. To avoid objectionable distortion under such a load were no means of reduction to sine-wave basis used, the generator kva. rating would have to be much larger than the transformer rating. (With a dependable method of reduction to sine-wave basis, very much smaller ratios of generator capacity to transformer capacity may be used in such tests.)

Heretofore approximate correction for wave distortion has been made usually by means of a small auxiliary "standard" core calibrated on sine-wave voltage. This standard core is excited from the same source simultaneously with the transformer under test, and with the aid of its calibration curve a correction is applied either to the test voltage or to the wattmeter reading.

This method of correction for wave distortion, though infinitely better than the use of no correction at all, is not very satisfactory, because no standard core could be representative of sheet steel of all grades and types used, nor of the wide range of densities at which different transformers are designed to operate. Under unfavorable conditions the use of a "standard" core has been found to lead to errors of even more than 10 per cent.

Since hysteresis loss is not a fixed known function of density for all kinds of sheet steel at all densities, obviously the only way to assure correctness of the tested value is to maintain the correct maximum flux density. Mathematically it has been proved that the maximum flux density is proportional to the arithmetic *average value* of the voltage, and therefore that with an instrument reading the average value of an alternating voltage instead of its r. m. s. value, correct density in the transformer under test can be preserved irrespective of the voltage wave shape. If an average-reading voltmeter is calibrated on a sine wave or, more conveniently, on a d-c. source, and then is used to determine the test voltage, correct density and hysteresis loss in the transformer are assured. Results are practically independent of the type of core steel used in the transformer, and correction need be made only for the eddy-current component of the no-load loss. This is a relatively small correction and can be made very accurately.

The average-voltage method was not commercially practicable until a few years ago when G. Camilli showed how an average-reading voltmeter could be constructed using a vacuum-tube rectifier and d-c. voltmeter. Since the instrument was to be used for maintaining correct flux in a transformer it was named appropriately a "flux voltmeter." "A Flux Voltmeter for Magnetic Tests," A. I. E. E. Jl., October 1926, p. 989, disc. 1014.) Since then the instrument has been improved further by the use of a small copper-oxide rectifier instead of the vacuum-tube rectifier, and is available commercially.

In addition to the much greater accuracy obtained by the average-voltage method, there is the advantage that a given no-load-loss measurement can be checked very easily even in the field by any one using a flux voltmeter. The calibration of the instrument also is simple; it can be done on direct current.

Suspension Insulator Lifts 20-Ton Load

Westinghouse E. & M. Co. Photo

NEW developments such as railroad electrification with heavy cables tightly strung are demanding mechanical strength in insulators which requires all the designer's skill to furnish. Just as a demonstration of its strength this new 12-in. heavy-duty insulator, which is thought to be the strongest of normal type ever built, may be seen lifting a 20-ton steel car off the rails, trucks and all. The greater strength has been obtained not by using more material but by a more accurate knowledge of materials in general, and a more precise calculation of the distribution and transfer of stresses.

Insulation Research Advances Are Recorded

The quest for a better understanding of important problems underlying the improvement of electrical insulation is proceeding definitely through channels of research into related fundamentals, as outlined in the January issue of ELECTRICAL ENGINEERING (pp. 24-29). During the first half of 1931 some seven papers have been presented before Institute conventions and District meetings covering certain specific efforts in insulation research. Two of these papers concerned themselves with cable oils, two with impregnated paper, and three devoted primary attention to mathematical attacks upon insulation problems. In whole or in part in several instances these same papers were discussed at the Washington, D. C. meeting (Nov. 7-8, 1930) of the National Research Council's electrical insulation committee, which conference was comprehensively reviewed in the January 1931 issue of ELECTRICAL ENGINEERING. All of the papers in question have been reviewed briefly in current news reports appearing in ELECTRICAL ENGINEERING, but because of the importance of the subject and for the benefit of those it may serve, the following group of brief abstracts is published.

The Conductivity of Insulating Oils

By
J. B. WHITEHEAD
Fellow A. I. E. E.
Johns Hopkins University, Baltimore

CONTINUOUS-CURRENT characteristics of several insulating oils are studied for time intervals beginning 0.001 sec. after the application of voltage or short circuit. Essential equipment is the amplifier oscillograph in connection with a quick-acting switch. It is found that in one group of oils there is an initial conductivity which is constant over the period of the first second following the application of the voltage. Thereafter there is a slow decrease of conductivity to a final value much lower than the initial value. It is shown that this initial constant conductivity is sufficient to account for all of the dielectric loss under alternating stress.

In another group of more carefully refined and deaerated oils there is superposed upon the brief initial constant conductivity a still shorter initial evidence of dielectric absorption. During the first few thousandths of a second the charging current decreases sharply; is followed thereafter by a constant conductivity up to about one second, and thereafter decreases further to a much lower value after a long time. The initial absorption period has a corresponding discharge curve on short circuit. The measured value of the alternating loss in this case is completely accounted for by the sum of the loss due to the initial period of absorption in combination with the succeeding short-time-constant conductivity.

Other results are presented on the variations of the initial and final conductivities with the voltage and with temperature. The final currents show saturation characteristics, but the initial high conductivities do not.

Among the conclusions reached are the following:

1. Certain high-grade insulating oils have electrical characteristics similar in type and comparable in magnitude to those of the carefully refined poorly conducting liquids used in physical research.

Conductivities of the order 10^{-15} mhos per cu. cm. are common.

2. In the purest state they show a definite though brief dielectric absorption.

There are in fact three definite stages of conductivity: (A) an initial brief, rapidly descending value with corresponding curves for charge and discharge current, thus indicating the presence of dielectric absorption.

From "The Conductivity of Insulating Oils," (No. 31-40) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

The duration of this phase is of the order of 0.004 sec. (B) An approximately constant value of conductivity within the interval 0.004 to 1 sec. (C) A very slowly decaying conductivity reaching a constant value only after 30 min. or more.

3. Initial dielectric absorption increases with decrease of temperature and thus is associated with the viscosity.

It is difficult to measure at 60 deg. or in an oil slightly deteriorated. In these cases the absorption, if present, is obscured by the greater value of conductivity of stage (B).

4. Dielectric loss under 60 cycles alternating stress is determined definitely by the continuous-current characteristics, within the interval 0 to 0.1 sec.

Loss at the higher temperatures and for oils having high initial conductivity is accounted for completely by the conductivity of stage (B). For the purest and best oils below 60 deg. the alternating loss is accounted for completely by the conductivity of stage (B) plus the loss computed from the curve of dielectric absorption pertaining to stage (A). At 80 deg. this second component may represent 35 per cent of the total loss.

5. Initial absorption, conductivity, and subsequent decay are not completely accounted for by residual impurities, as frequently stated.

It is highly probable that they are due in part to the variety of molecular complexes and groupings occurring in such hydrocarbons, resulting in a heavy slow-moving type of ion which is subject to wide variation in properties with the value of the electric intensity and with other external influence. Thus these ions which give rise to the initial stages of conductivity probably are quite different from those involved in the final conductivity, and which have been used by Jaffe and others for drawing analogies between the conductivity of a liquid and of a gas. In fact there is no immediate evidence that this latter type of ion is involved in the alternating loss at commercial frequencies.

Some Electrical Characteristics of Cable Oils

By
HUBERT H. RACE
Assoc. A. I. E. E.
General Electric Co.
Schenectady, New York

ROUTINE measurements of d-c. resistivity are dealt with in the first part of this paper, along with a description of a quartz-insulated testing cell and a portable testing set for use with it. Absolute resistivity between 1×10^9 and 1×10^{13} ohms can be measured at any temperature up to 150 deg. cent. Among the conclusions are:

1. Data indicate that for comparative resistivity measurements it is necessary that the samples be thoroughly dry and that they be protected from light and heat before the measurements are made.

2. For comparing the electrical characteristics of commercial insulating oils, d-c. conductivity measurements are preferable to low-frequency bridge measurements since they give the same information and are easier to mak.

Variation of apparent d-c. conductivity of a heavy cable oil with potential gradient and with temperature are shown in the second part of this paper. Data show that the conductivity is constant only for very low gradients. An approximate mathematical relation is developed to represent the conductivity both as a function of potential gradient and of temperature. Measurement of the apparent d-c. conductivity of a heavy cable oil as a function of temperature and of potential gradient gave the following results:

1. Potential gradient must be kept below 20 volts per mil to assume constant conductivity for temperatures as high as 100 deg. cent.

2. The lower the temperature the higher the critical gradient below which conductivity is independent of gradient.

3. The lower the temperature the more rapid the increase in conductivity for gradients higher than this critical gradient.

4. Variation of apparent d-c. conductivity with both temperature and potential gradient may be represented approximately by the equation

$$\gamma = \gamma_0 \, \epsilon^{\alpha T} \, \epsilon^{\beta g}$$

in which, for the oil tested,

$\gamma_0 = 3.48 \times 10^{-23}$ mho. per cm.^{3}
$\alpha = 0.0683$ per deg. abs.
$\beta = 12.64\,(100/T)^6$ per volt per mil.
T = temperature in deg. abs.
g = maximum potential gradient in volts per mil.

5. In conducting those experiments, convection currents wer observed in the oil, indicating that the increase in conductivity at high gradients may result from increased mobility of charged aggregates.

Observed variations of dielectric coefficient and dielectric loss with temperature and frequency for a viscous cable oil are summarized in the third part of this paper. Analysis shows the total dielectric loss to be the sum of two components, one due to conduction and the other qualitatively explained by Debye's theory of polar molecules. On the basis of measurements made on carefully refined water-free mineral insulating oil through a temperature range from − 50 to 150 deg. cent. and a frequency range from 300 to 2×10^6 cycles per sec., it is apparent that:

1. At frequencies lower than 300 cycles per sec. and at temperatures greater than 25 deg. cent., the total dielectric loss may be accounted for by conduction only. Thus at 60 cycles per sec. it is only at very high viscosities that there is any appreciable loss except that resulting from conduction. For this reason d-c. conductivity measurements are sufficient in comparing the electrical characteristics of insulating oils, when made according to conditions discussed in Part I of this paper.

2. At higher frequencies and lower temperatures the conduction loss becomes small compared to an a-c. loss which may be qualitatively explained on the basis of Debye's theory of polar molecules. While it is true that Debye's theory has given qualitative agreement with observed data, it is possible that similar relations may be developed on the assumption of the motion of charged particles in an ionic atmosphere.

3. In mineral oils having lower-viscosity, but about the same conductivity, this a-c. loss is negligible at even lower temperatures and higher frequencies than for the more viscous oil.

4. For oils containing larger amounts of polar constituents, such as castor oil or oil-rosin mixtures, this a-c. loss may be appreciable even at commercial frequencies and temperatures.

5. Data indicate that it is dangerous to draw conclusions as to the characteristics of a material from measurements taken only for narrow ranges of experimental conditions. Studies over wide ranges of frequency and temperature may explain apparent discrepancies between results of different experimenters working within different limited ranges of measurement.

From "Some Electrical Characteristics of Cable Oils," (No. 31-47) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

Fundamental Properties of Impregnated Paper

By
J. B. WHITEHEAD
Fellow A. I. E. E.

W. B. KOUWENHOVEN
Member A. I. E. E.

Both of Johns Hopkins University, Baltimore

FIRST results are given in this discussion covering a study of the separate electrical behavior of the paper, the impregnating oil, and the combination thereof which constitutes impregnated insulating paper. Where possible, efforts were made to determine the relationship existing between fundamental and final characteristics.

The materials used constituted two essentially identical paper specimens and two oil specimens drawn from the same batch. The paper samples were carefully dried prior to testing; one of the oil specimens was used "as is" and the other was deteriorated by heating in the presence of air until its dielectric loss and conductivity were approximately double that of the other specimen. All specimens were tested separately; subsequently combinations of the paper specimens with the two different oil samples were tested.

Test procedure involved the use of both continuous and alternating potentials for the determination of temperatures ranging from 30 to 60 deg. cent. Short-time oscillograms and long-time values of charge and discharge currents were measured using continuous potentials; power factor, capacitance, and dielectric loss were determined with alternating potentials. All of the a-c. loss in the paper specimens can be accounted for by absorption, while the dielectric losses in the oils can be accounted for entirely by the short-time conduction and brief initial dielectric absorption.

The two impregnated-paper specimens were found to be alike, in that their voltage-power factor curves were straight lines and that their losses increased in proportion to the square of the test voltage. Some noteworthy differences, however, are worth mentioning:

1. The shape of the loss-temperature curve for the paper specimen impregnated with the poorer oil had a U shape, while the other showed a curve that was falling over the entire range of temperature studied.

2. Although initially both paper specimens had the same capacitance, the one impregnated with the poor oil of high conductivity and lower dielectric constant had a greater resulting capacitance than the other which was impregnated with the good oil of low conductivity, but of greater specific inductive capacity.

3. Dielectric loss in both impregnated specimens was greater than the sum of the individual losses in the paper and oil used in their production and may be completely predicted from the short-time continuous-voltage records.

4. Electrical characteristics of paper are changed by impregnation. The reversible absorption and the irreversible charging current both are increased by the conductivity of the oil.

The differences in the characteristics of the two impregnated specimens were due to the differences in the initial conductivity of the two oil samples. The dielectric loss in the specimens has been analyzed and separated into three components; reversible absorption, irreversible conduction current, and final conductivity. The loss due to short-time conduction may be as high as 30 per cent of the total loss, and 250 times the loss as computed from the final conductivity.

From "Fundamental Properties of Impregnated Paper," (N . 31-45) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

Air and Moisture versus Paper Insulation

By
J. B. WHITEHEAD
Fellow A. I. E. E.

F. HAMBURGER, JR.
Assoc. A. I. E. E.

Both of Johns Hopkins University, Baltimore

THIS is the third of a series of studies into the still open question of the influence of residual air and moisture upon the properties of impregnated-paper insulation. The influence of residual moisture was found to be universally bad and increasing amounts of such moisture are immediately reflected in higher values of power factor and loss and in other evidence of instability. One of the most striking results of the earlier studies was the relatively small effect of residual air upon the shape of the voltage-power factor curves. The shape of these curves was not appreciably affected in the range of evacuation pressure from 1 to 10 cm. Hg. abs. and furthermore the curves were flat up to 300 volts per mil and 50 deg. cent. Only at impregnation pressures above 25 cm. Hg. do the typical rising power factor-voltage curves become evident. Upon dissection, dryness and gas voids always were associated with rising power factor-voltage curves, and apparently-excellent impregnation with the flat curves.

The present paper presents the results of studies of the influence of residual air upon the life of the finished insulation. The value of the pressure of evacuation and impregnation was used as a measure of the amount of residual air. The test sample consisted of a brass tube 1 in. in diameter and 4 ft. long upon which were wrapped 15 layers of 0.0043 in. manila cable paper 1

From "Residual Air and Moisture in Impregnated-Paper Insulation —III," (No. 31-95) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

in. wide. In all respects excepting certain modifications for strengthening the ends to withstand the higher voltages requisite for the accelerated life test, the sample was similar to that used in the earlier studies.

In view of the influence of residual moisture, all the samples were dried to the same standard value of d-c. conductivity before impregnation and then evacuated and impregnated at various values of pressure as a measure of their air content. The usual program in the accelerated life test was to start at 400 volts per mil, followed by 500 and 600 volts per mil at 1-hr. intervals, thereafter advancing to 600 and 650 volts per mil at 10-hr. intervals, followed by 700, 750, 800, 850 volts per mil for increasingly long periods. This program resulted in a life in the neighborhood of 12 hr. for the poorest specimens, but in several cases of better grade, the life reached a week and more without sign of distress at prolonged periods of 850 volts per mil. In these tests the temperature remained constant at 40 deg. cent.

A summary of the conclusions is as follows:

1. The life of impregnated-paper insulation increases steadily with a decrease in the amount of residual air.
2. For impregnating pressures above 2.5 cm. the life decreases rapidly with increasing pressure of impregnation. For pressures below 2.5 cm. the results show an increase of life of from 10 to 50 per cent between 2.5 cm. and 2 mm. impregnating pressure.
3. For impregnating pressures below 2.5 cm. normal variations in material and structure, particularly in the tightness of the structure, may offset the increased life due to decreasing the pressure of impregnation.
4. Cable compound deteriorates if it contains only a small amount of air, even though it is kept in sealed containers at room temperature. Air should be entirely excluded to avoid deterioration.
5. Flat power factor-voltage curves and the absolute value of power factor should not be accepted as indications of long life.
6. Power factor rise due to the initial application of voltage during a life test is indicated as a possible criterion of insulation life.
7. A very satisfactory type of sample and reenforced cable-end for accelerated life tests has been developed.
8. Narrow variations in the quality of both paper and oil may cause wide differences in the electrical characteristics and in the lives of the impregnated products.

Insulation Variability

By
M. C. HOLMES
Assoc. A. I. E. E.

West Virginia University, Morgantown

THIS paper constitutes a theoretical investigation of the effect of insulation variability in determining the breakdown voltage of systems containing large areas of insulation, or large numbers of units of insulation in parallel. It is based upon the idea that a failure in the insulation of a system, like that of a chain, depends upon the strength of the weakest part, or unit; and that the greater the number of units in a system and the greater the variability among the units the greater will be the likelihood of a failure. The analysis, therefore, makes use of the laws of probability which incidentally are more exact and of greater practical importance than is generally believed.

That the results of the investigation may be immediately applied and tested in engineering they are given in the form of two general equations. These two equations give in terms of two parameters either the breakdown voltage of a system or the number of failures to be expected. The parameters are (1) mean breakdown voltage and (2) variability of the units of insulation of which the system is composed, both determined from tests made on samples. The paper shows how the results may be applied to the special case of electric power cables for comparing the relative merits of different cables and for determining the factor of safety required to take account of the inherent variability of the insulation. A graphical method of analysis also is described which makes use of a special kind of graph paper called "probability" paper. In the case of cables the probability coordinate is changed from "per cent" to "failures per 100 miles of cable per year."

The two general equations, and the meetings of the symbols, are as follows:

$$F = N\left[1/2 - \mathrm{erf}\left(\frac{1 - E_o/E_a}{S}\right)\right] \tag{1}$$

and

$$E_b = E_a\,[1 - S\,.\,\mathrm{erf}^{-1}\,(1/2 - 1/(2\,N))\,] \tag{2}$$

The first equation gives the number of failures F to expect in a system containing N units of insulation at an operating voltage E_o, the units being assumed removed from the system upon failure. The two parameters E_a and S may be considered as representing the quality of the insulation as regards resistance to rupture, E_a being the mean breakdown voltage of the units and S the coefficient specifying the variability of the insulation. The second equation gives in terms of the same two parameters the breakdown voltage E_b for a system of N units of insulation connected in parallel.

The symbol *erf* is an operator used to denote the Gaussian error function, the value of which may be obtained from tables similar to tables of sines and cosines. The symbol erf^{-1} represents the inverse operation just as the symbol sin^{-1} represents the inverse of *sin*. Values of $erf(x)$ and $erf^{-1}(x)$ may be obtained from tables, then, just as are values of $sin(x)$ and $sin^{-1}(x)$ The equations therefore are quite simple and easy to apply in spite of their formidable appearance.

The coefficient S, specifying the variability of the insulation, is calculated from the results of breakdown tests on samples. It is the standard deviation, sigma, expressed as a decimal fraction of E_a. Sigma is defined by the following equation:

$$\text{sigma} = \sqrt{\frac{\Sigma\,(\delta)^2}{n}} \tag{3}$$

where $\Sigma\,(\delta)^2$ represents the sum of the squares of the deviations of individual breakdown voltages from their mean, and n is the number of test results considered.

The two equations are entirely general. Specific equations may be obtained from them and applied to all kinds of insulation, either in the form of continuous areas as in cables, or in the form of discrete units as in

---

From "Insulation Variability—Its Influence in Determining Breakdown Voltages," (No. 31-99) presented at the A. I. E. E. summer convention, Asheville, N. C., June 22-26, 1931.

overhead transmission lines. In the former case N represents length of cable measured in terms of some standard test length; in the latter case, N represents the number of units of insulation under voltage stress, for example the number of strings of insulators along an overhead line. In the case of thin sheets of insulation N may be taken to represent electrode area; equation (2) then gives breakdown voltage as a function of electrode area as well as insulation variability. It therefore constitutes a distinct advance over the well-known equation of Milnor's which takes account only of the effect of area.

In the past too much attention has been paid to mean breakdown stresses or to the extremely high stresses exhibited by a few samples of insulation, and not enough to the question of variability. The present paper shows that the variability is at least equally important, and often is the *more* important because it is the strength of the weakest unit—not the mean strength of all the units—which determines the strength of the entire system.

Thermal Breakdown of Solid Dielectrics

By
P. H. MOON
Member A. I. E. E.

Massachusetts Institute of Technology, Cambridge

THE purpose of this paper is to correlate the work which has been done on thermal breakdown and to put it in a form in which it can be used by the electrical engineer in the calculation of breakdown voltage. Besides a treatment of the Fock theory, the paper includes the derivation of new formulas for breakdown of very thin and very thick samples and for internal temperature rise and current.

A startling fact brought out by this analysis is that before breakdown the internal temperature never rises more than about 10 deg. cent. above ambient temperature.

The three Fock tables of breakdown voltage are extended to cover a wider range of temperature and all thicknesses, and the results are put in several forms convenient for numerical calculations. Breakdown voltage hitherto has been calculated by a tedious cut-and-try process using all three tables. In the present paper this has been simplified and the results given in the form of new curves and tables, thus greatly reducing the labor required for breakdown calculations. Experimental data are presented to verify the theory.

Equivalent Circuits of Imperfect Condensers

By
C. L. DAWES
Member A. I. E. E.

W. M. GOODHUE
Non-member

Both of Harvard Engineering School, Cambridge, Massachusetts

IMPERFECT condensers usually are represented by equivalent electrical circuits consisting either of a pure capacitance and a resistance in series or by a pure capacitance and a resistance (or conductance) in parallel. Algebraic relationships existing among these circuit parameters are well known and commonly are used in dielectric study and electric circuit computations. For most dielectrics the equivalent series and parallel capacitances are essentially equal; in this paper examples are given where this is far from true.

The purpose of this paper is primarily to show quantitatively the application of these equivalent series and parallel circuits to composite dielectrics consisting of solid dielectrics and ionized gases in series, and more particularly to high-voltage cables having degrees of ionization varying from practically zero to very high values.

With a composite dielectric consisting of a slab of glass in series with a film of ionized gas the equivalent series resistance for the fundamental component of current varies with the current density and, so far as heretofore has been known, its characteristic was merely a curve more or less indefinite in character. In this paper it is shown that this characteristic is a definite and relatively simple function of the current density and that it has a maximum value which is readily computed from the constants of the composite dielectric.

The characteristics of high-voltage cables hitherto have been given in terms of equivalent series and parallel capacitance and in terms of equivalent parallel resistance. The equivalent series and parallel capacitances in most cases are practically equal; even for

values of power factor as high as 12 per cent they differ by only 1.5 per cent.

The equivalent parallel resistance and conductance and the equivalent series resistance of cables having ionization hitherto have been expressed by curves which seemed to have had no analytical basis. In this paper, however, it is shown that such curves (with the exception of the region of successive ionization) can be expressed by relatively simple analytical equations; also the curves of the equivalent parallel conductance and equivalent series resistance can be analyzed into three simple component curves. Moreover, at the ionization voltage these curves rise rapidly to a maximum and then decrease more slowly. This maximum value and the voltage at which it occurs are readily calculated, being very simple functions of the characteristic cable contants. These curves also are shown to be very similar to the power factor curve and to differ from it by only a coefficient $C\,\omega$ that is nearly constant.

Thus this paper puts on a moderately accurate quantitative and analytical basis what hitherto have been merely cable curves having no apparent relationship to the inherent cable constants.

Equivalent series and parallel parameters of ionized gas films taken by themselves also are analyzed, with only the fundamental component of current considered. It is shown that the equivalent series resistance of such films may be expressed fairly accurately by a simple equation, and that the characteristic has a definite and sharp maximum which is easily computed.

Unlike cables, the equivalent series and parallel capacitance of ionized gas films differ radically from each other in value. At large current densities the value of the equivalent series capacitance may be as high as six times the value of the equivalent parallel capacitance. Hence the two cannot be assumed to be equal as with ordinary cables and other dielectrics. The equations for the characteristics of an equivalent series capacitance can be determined from the characteristic curves themselves, but thus far it has been found impossible to relate them to any fundamental electrical property of the ionized gas.

Oscillograms show that with a sine-wave voltage the current in ionized gas films consists largely of harmonics, particularly those of high frequencies. It is emphasized in the paper that these harmonics render ambiguous many of the definitions which hitherto have been applied to dielectrics. Also most high-voltage bridges measure only the fundamental component of voltage and current. Hence it is recommended that for simplicity both in definition and in measurements, quantities relating to ionized gas films shall be defined for the present with reference only to the fundamental component of the current and voltage waves.

Water Power Exploitation in Switzerland

Switzerland is one of the few countries fortunate in having at its disposal more water power than its inhabitants can use conveniently. Hydroelectric power now is supplied to 90 per cent of the total population and to 98 per cent of all municipalities.

SWITZERLAND'S topographic, geographic, and economic situation contributed to bringing about the early and extensive utilization of the country's electric energy, not only for its railways but for various industrial and other purposes requiring motive power, says Prof. C. Andreae, engineer E. P. F., former rector of the Federal School of Technology at Zurich and now director of the Royal School of Technology at Guiseh (Egypt), in an article published recently in *Swiss Industry and Trade.*

A marked industrial development has taken place during the past century in Switzerland due primarily to the growing inadequacy of agricultural products to provide for the maintenance of its ever increasing population. Switzerland possesses no coal mines. Its rivers and waterfalls, however, are a source of great natural wealth and their exploitation has become a vital economic factor.

The total amount of this natural energy is estimated at 6,000,000 kw. and is capable of producing an annual output of 20,000,000,000 kw-hr. At the present time only 1,550,000 kw. is being utilized, the annual production amounting to 5,968,000,000 kw-hr. Nevertheless, in 1925 consumption had reached 820 kw-hr. per capita of inhabitants, without exports; including the latter the total per capita output exceeded 1,000 kw-hr. As would be expected from these facts there are surprisingly few people in Switzerland who do not enjoy to some extent the benefits of electricity, statistics indicating that 90 per cent of the total population and 98 per cent of all municipalities are supplied with this commodity.

The total area of Switzerland measures only 15,990

Contributed by F. Dossenbach, director of the Official Information Bureau of Switzerland, New York. Not published in pamphlet form.

sq. mi., or about twice the area of the state of New Jersey. This comparatively small area, however, embraces great differences in altitude, the highest point being 15,200 ft. above sea level; the lowest, 646 ft. Consequently declivities are extremely pronounced and stream beds exceedingly abrupt.

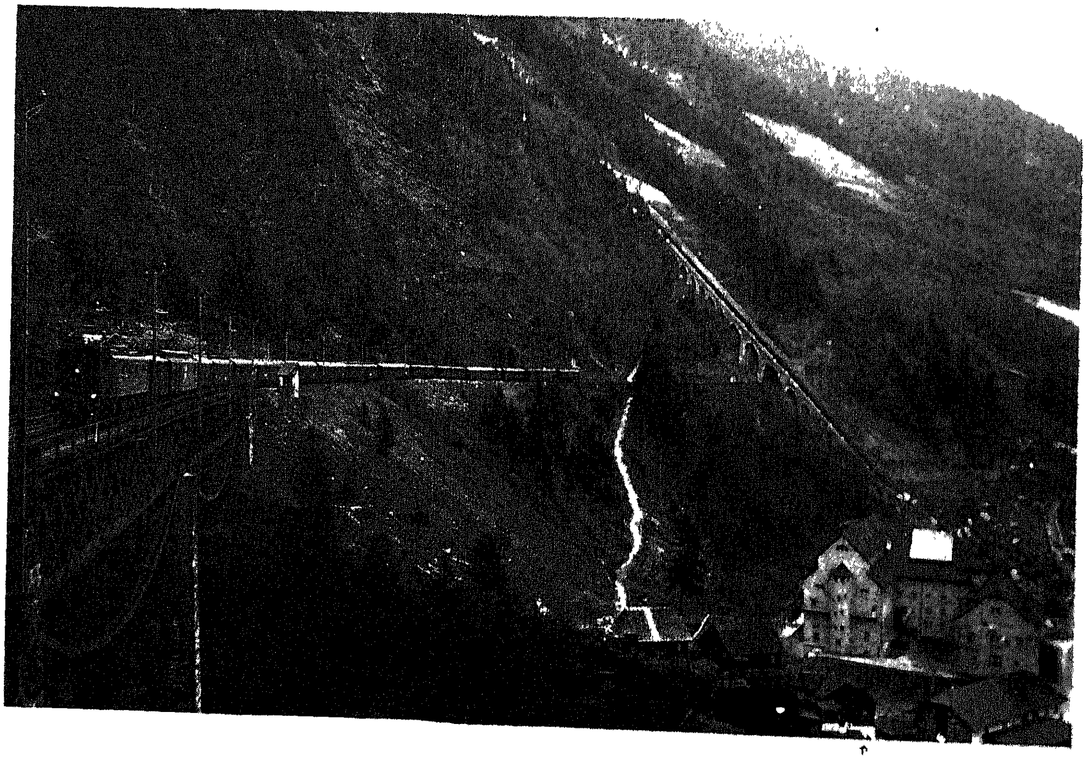
Judging from these facts, the prevalent conditions for hydroelectric development would appear to be favorable and simple. Switzerland's hydrologic régime, however, is peculiar; although 60 per cent of the precipitation occurs during the five winter months (November-March) and only 40 per cent during the seven summer months (April-October), rivers and streams are high in summer and low in winter. This is because winter precipitation takes place generally in the form of snow and remains stationary until the summer months. Consequently the energy produced directly in winter constitutes only one third of that obtained during the summer.

An exactly opposite situation exists as regards consumption and demand. Maximum consumption during a winter day is about 120 per cent of the average daily consumption throughout the year; for a summer day, the maximum is about 80 per cent of the average. An economical exploitation of this natural energy then obviously necessitates some measure to compensate for the divergency between output and consumption. Among the various methods advocated, the system of hydraulic accumulation during the summer, when output exceeds consumption, has proved the most economical and enjoys the greatest popularity.

Similar to the situation existing in the mountainous regions of western United States, accumulation is effectuated by means of dams allowing for the retention of the water during the summer. Accordingly, plants are constructed in the vicinity of the Alps where small streams with high heads produce relatively large quantities of electric energy with comparatively little water. Some plants have been constructed also on the lower portions of rivers and streams to utilize directly the heavy summer stream flow. During the summer months, these plants supply practically all demands, allowing those situated in the higher Alpine regions to fill their accumulation basins in preparation for the annual low-water period.

Considered from economic and financial points of view, these groups of power plants are not all organized upon the same basis. The Swiss Confederation owns the plants which supply tractive power for the state railways only. A small number are owned by the cantons or municipalities while others are operated by private companies. The most important groups, however, are owned by "mixed companies." These are limited companies in which the larger portion of the stock is in the hands of the cantons or municipalities. This combination, wherein private capital cooperates with public effort, has given excellent results in the majority of cases.

What will be the largest "accumulation" plant in all Europe is now under construction on the River Aare at Grimsel Pass. It will have two basins with a total capacity of 91,600 acre-ft. The principal dam will be 361 ft. high. Water is to be utilized in three instalments, with a total fall of 3,940 ft., and the ultimate plant capacity will be 250,000 hp. At present only the first instalment which will aggregate 120,000 hp., is being built. The waterfall for this initial development will be 1,770 ft. high, and the rate of flow, 642 sec-ft.



An excellent example of Switzerland's rugged topography showing a train of the electrified St. Gothard railway approaching the huge Kerstelenbach viaduct. At the right may be seen the Amsteg hydroelectric plant with its three penstocks running down the mountainside

Of Institute and Related Activities

And Next—The Tahoe Convention

The program has been published (pp. 514-6 ELECTRICAL ENGINEERING, July, 1931) and circulated to every member of the Institute; committees have been as busy as the proverbial bees gathering proverbial honey; Tahoe Tavern beckons with special reduced rates; the majestic Sierra Nevada await; Lake Tahoe is ready; and prospective speakers are (or undoubtedly should be) practising before favorite mirrors. In other words, the stage is all set for a most attractive Pacific Coast convention at Lake Tahoe, California, during the last week in August.

As hinted before, the forthcoming events offer opportunities attractively unique in the variety of things those in attendance may do, in addition to participating in a good technical program. Just to mention a few, there's hiking, fishing, boating, swimming, golfing, and Reno. And then there is the fact that transportation rates from many points are the lowest that they ever have been. Last, but not least, there is the cordial invitation of General Chairman A. W. Copley (vice-president-elect) to "come and bring the family."

Kansas City is Host to October Meeting

The South West District No. 7 of the A. I. E. E. will hold a three-day meeting at Kansas City, Missouri, October 22-24.

Four technical sessions have been tentatively scheduled, the first of which will comprise papers on a variety of subjects: building-construction welding, relay operation as affected by wave form, pilot-wire relaying, computing currents in network loops, backfires in rectifiers, overvoltages due to the dropping of load, and surge tests on a distribution substation. The three other sessions will include papers on: St. Louis-Bagnell interconnection, communication, and transmission and distribution. At the interconnection session a three-reel motion picture of the actual construction of the Bagnell dam will be shown.

In addition to the foregoing technical program there will be two student sessions at one of which papers by the students will be presented.

Other features of the program will consist of entertainment, inspection trips, and recreation. These will be announced in detail in a subsequent issue of ELECTRICAL ENGINEERING, together with a full listing of the papers to be presented.

Officers, Delegates, and Members Hold Animated Sessions at Asheville

Following the plan inaugurated in 1930, the conference of officers, delegates, and members, held under the auspices of the Sections committee and the committee on student Branches, met on Monday and Tuesday afternoons, June 22 and 23.

The attendance of official delegates was larger than ever before; representatives included 52 of the 59 Sections, all of the ten District secretaries, and counselor delegates from eight of the nine Districts in which committees on student activities have been organized. Institute and Section officers, Branch counselors, and other members present brought the total attendance to about 110.

After a brief opening session on Monday afternoon, sessions A and B were held in parallel, Everett S. Lee, chairman of the Sections committee, presiding over session A devoted to Section activities, and Prof. W. J. Seeley, a member of the committee on student Branches, presiding over session B which dealt with problems concerning the Branches and enrolled students of the Institute. Tuesday afternoon was devoted to a joint meeting of the two groups to discuss subjects of common interest.

The topics in a conference program, which had been mailed to delegates and others in advance, are given in the following outline:

Monday, June 22, 2 p. m.

1. Opening of conference:
   Announcements by Everett S. Lee, chairman of the Sections committee.
2. Remarks by W. S. Lee, president.
3. Remarks by C. E. Skinner, president-elect.
4. Remarks by F. L. Hutchinson, national secretary.
5. Division into parallel sessions of Section and student Branch delegates and members.

Session A—Sections Meeting—Everett S. Lee presiding.

6. The Institute Membership—J. Allen Johnson, chairman membership committee.
   a. The licensing or registration of engineers.
   b. Establishing a high professional standing of engineers in civic and other affairs.
   c. How to create an interest in members of six or more years standing in transferring to the grade of Member or Fellow.
7. Conduct of Sections—H. H. Henline, assistant national secretary.
   a. Finding new material for officers.
   b. Types of programs and speakers; frequency of meetings.
   c. How to build up and maintain interest of members in sections by technical and entertainment programs, and social features.
8. Finances—A. C. Stevens, secretary, District No. 1.
   a. Financing of Sections and District meetings.
   b. Financing of Section contact with local engineering societies.

Session B—Student Branch and Enrolled Student Meeting—Prof. W. J. Seeley presiding.

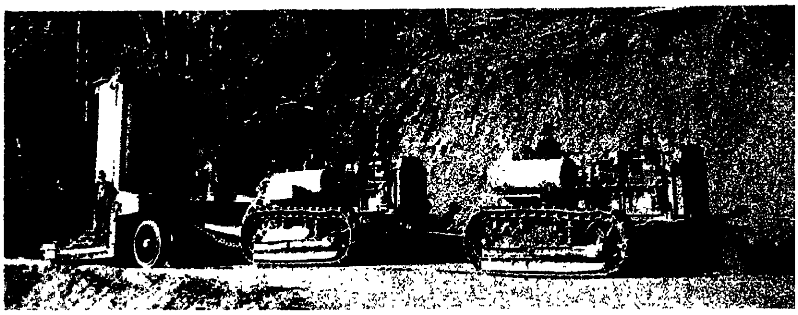
9. The problem of interesting the better high school students in electrical engineering—Prof. W. H. Timbie, chairman committee on student Branches.
10. The most advantageous time of year for holding student conferences—Prof. Joseph Weil, counselor delegate, District No. 4.
11. Coordination between the Branches and Sections, national organization, and practising engineers—Prof. G. H. Sechrist, counselor delegate, District No. 6.
12. Conduct of Branch business—Prof. G. L. Hoard, counselor delegate, District No. 9.
13. Financing the chairmen of the District student Branch committees—Prof. D. C. Jackson, Jr., counselor delegate, District No. 7.

Tuesday, June 23, 2 p. m.

Session C—General—Everett S. Lee presiding.

14. The Institute and the student—Prof. W. H. Timbie, chairman committee on student Branches.

Transportation in Electrical Construction



SINCE those in attendance at the Pacific Coast convention at Lake Tahoe, California, will have the opportunity to visit the recently completed Tiger Creek plant of the Pacific Gas and Electric Company on the Mokelumne River, it is of some interest to note the contrast in transportation facilities available for this latest job as compared with those available for the company's early De Sabla plant built on the same stream in 1904.

- a. How to get the facts regarding the electrical engineering profession before juniors and seniors in high schools.
- b. Cooperation between local Sections and student Branches.
- c. Meetings of local Sections conducted by younger engineers.

15. General.
    - a. The extension of the scope of A. I. E. E. activities to include more of "the economic aspects of engineering" and "engineering views on non-engineering subjects."
    - b. Index of engineering literature as now published in **Electrical Engineering**. To what extent is it used? Should it be extended or condensed?
    - c. Questions and answers in general.

Copies of the annual report on Section and Branch activities for the fiscal year ending April 30, 1931 were distributed. These may be secured without charge to Institute members by applying to headquarters.

During the discussion on Section activities it was agreed that the Sections committee will consider the problems of such Institute members as are interested in a particular Section but located either in the territory of another Section, or outside the territory of any Section.

RECOMMENDATIONS ADOPTED

A resolution was adopted recommending to the board of directors that,

1. A national standing committee on transfers be created consisting of five members.
2. A local committee on transfers of three members be created in each Section.

The conference voted hearty approval of the recommendations of the committee on student Branches as reported by Chairman Timbie, for supplying information regarding electrical engineering as a career to high school teachers and students.

A motion was adopted recommending to the board of directors that the allowance of traveling expenses for visits of the vice-presidents to Sections and Branches in their Districts be increased is feasible, in order that a vice-president may be able to make many visits without incurring a considerable personal expense.

Decisions of the counselor delegates upon subjects not considered by the conference as a whole are summarized below:

The time of year at which District conferences on student activities should be held should be selected by each District according to its needs.

While some outside speakers are desirable, generalizing, the Branches should have very few.

The counselor of each Branch should instruct new officers regarding their duties and should insist that the Branch secretary report all meetings to headquarters.

The appropriation of $200 per year was recommended to defray the expenses of postage, stenographic service, etc., required by the chairmen of the District committees on student activities.

An abstract of the proceedings of the entire conference will be printed in pamphlet form and mailed to all delegates present; also to Institute, Section, and Branch officers. Any member of the Institute may secure a copy without charge by applying to headquarters.

"Slide Rule" for Lamp Calculations

As part of its development and educational campaign directed toward improved illumination efficiency, the Nela Park engineering department of the General Electric Company, Cleveland, Ohio, has issued recently a simple combination celluloid-and-cardboard slide rule. This device is designed to reveal the voltage-operating characteristics of electric lamps and to simplify the analysis of the economics of incandescent lighting. For any voltage condition the calculator makes easy the determination of the quantity of light that will be produced, the quantity of energy consumed, and the lamp life, thus showing at just what point the most light may be obtained for the least total cost.

With the improved quality of lamps now available, and the low prices prevailing, Nela Park states that generally the cost of current represents approximately 90 per cent of the cost of light under average conditions. Thus a variation of 1 per cent in lamp efficiency is as important as a range of 10 per cent in lamp price. The slide rule reveals quickly that operation of an incandescent lamp at slightly under voltage appreciably increases the lamp life, but also reduces lighting efficiency to a point which brings the total cost of illumination to a figure several per cent higher than would prevail if the lamps were operated at rated voltage. The lamp-characteristic calculator is available through the sales offices of the Edison Lamp Works and the National Lamp Works of the General Electric Company.

Summarized Review of Some Summer Convention Discussions

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized; complete discussion together with all of the papers will be published in the Transactions. The titles of the papers and the names of their respective authors were published in Electrical Engineering, May 1931, pp. 370-1.

Communication Services for Electric Utilities

H. S. Phelps, in his discussion of this subject, stressed the importance of high quality of voice transmission on the part of the system devoted to the use of system load dispatchers. He explained also that considerable "transmission margin" should be provided to assure good communication in the event of system expansion or the emergency of rerouting communication circuits.

F. R. Innes discussed the use of a remote metering system, quickly responsive to changing load conditions, to communicate to one point and to one man a complete "picture" of the system load. Such a system would facilitate load division between stations and result in a more stable system operation.

Electrical Machinery

L. P. Shildueck discussed "Reestablishing Excitation of a Loaded Alternator in Parallel with Others," pointing out that to prevent damage to the rotor excitation should be reapplied as soon as possible. He analyzed the conditions resulting when a turbine generator upon loss of excitation runs as an induction generator above synchronous speed at some slip determined by the governor setting. At a condition of 2 per cent slip, rotor losses would be 1,500 per cent of normal and high body currents concentrated at the ends of the machine might burn the rotor wedges and cause considerable damage. For these reasons excitation and operation at synchronous speed should be reestablished very quickly; otherwise the machine should immediately be disconnected from the line.

L. L. Perry discussed this same paper with particular reference to the application of the facts presented to the triple-compound unit comprised of one high-pressure generating unit and two low-pressure units. In the event of accidental opening of the high-pressure generator field the prompt reestablishment of excitation (instead of opening the circuit breaker and admitting high-pressure steam to the low-pressure turbines) would result in considerably less momentary loss to the system and in quicker restoration of the load previously carried.

M. L. Henderson discussed "Calculation of Synchronous-Machine Constants," and analyzed the formula for end-winding leakage which he found yielded results comparable with those obtained by different methods. In conclusion he expressed hope that the nomenclature for machine dimensions, number of phases, number of slots, etc., used by different designers would arrive at a steady state. This would save a great deal of the user's time when comparing with the results of another writer.

H. Poritsky discussed "Field Transients in Magnetic Systems," and suggested an equally illustrative yet simpler example than the one given in the paper. In place of an iron core he suggests a yoke of width w considerably larger than the thickness t. A case is obtained which results in a one-dimensional problem in the heat equation, and from which the Bessel functions would be eliminated in favor of hyperbolic or circular functions.

Automatic Stations

M. E. Reagan discussed "An A-C. Supervisory Control System" and its proposal to use alternating current from the supply lines for supervisory control. This fact resulted in each case in the ultimate abandonment of similar systems proposed during recent years. He believed, however, that the system has several novel features which will tend to increase the reliability factor and that only time will give a true comparison to the storage battery systems.

F. H. Hollister read a discussion by T. G. Robinson on "Automatic Combustion Control," which verified the practise and results given in the paper. It also was explained that of late there has been a desire to eliminate multi-speed induction motors used to drive draft fans. This has led to the application of variable-speed Rossman drives for draft fans. Recent tests and analysis of one boiler installation in the Chicago area indicated an approximate 4 per cent overall increase in efficiency which corroborates the statement in the conclusion of this paper.

I. M. Stein also discussed this subject and made a plea that installations be kept as simple as possible rather than following the tendency to make them complicated just because automatic controls can handle complicated installations. He urged that station auxiliaries should be designed or selected with the requirements of automatic combustion control fully in mind.

M. C. Reagan discussed "Operating Experience with Automatic Control" with reference to the argument in the paper that in general, maintenance charts are not good for getting a complete, accurate record of operation. He believes that this may depend largely upon the type of form used. Some operators have found this to be the one method of obtaining good maintenance records.

One of the points discussed by C. E. Stewart in connection with this paper was the use of the mono-wire or direct-wire system. He believes that this system for short distances over privately owned wires is undoubtedly the most economical in first cost. Whether the sacrifice in flexibility to meet future rearrangement of the supervisory equipment due to changed operating conditions, future growth, etc., offsets this advantage is questionable and must be determined by local conditions. Maintenance of automatic equipment also was ably discussed by Mr. Stewart who pointed out that today more time is spent on preventative maintenance. Mr. Stewart also discussed miniature switchboards stating that considerable advance has been made in the design of suitable control keys and meters so that now the miniature switchboard is considered a standard type of board for installations in power and switching stations. They effect improved operating conditions and economies.

M. C. Reagan discussed miniature switchboards pointing out that the statement regarding increased intervals between maintenance periods corresponds to the experience of a great many operating companies. He cited that where equipment is kept in near-dust-proof cases, less maintenance yields better results.

Symposium on Interconnections

H. K. Sels discussed the papers presented in this symposium and in particular he would like to see the definitions in the paper entitled "Interconnection Services—Their Classification and Evaluation," accepted as standard. He pointed out that one engineer refers to "load diversity" where another calls it "peak diversity;" "economy flow" also is called "dump power." Furthermore, in contractual relations, accepted definitions would provide useful terms in writing contracts which would have a better legal status.

H. G. Harvey discussed the same paper saying that with a few very obvious modifications the main service divisions outlined in the paper could be applied to reactive kva. as well as to true power flow or kilowatts. In further discussion Mr. Harvey called attention to a momentary emergency service caused by a surge originating on one system affecting the other. In some cases this condition has been a source of difficulty, and so far as is known no means have been devised to adjust for it equitably.

M. M. Samuels in discussing the same paper from the executive standpoint emphasized the importance of engineers submitting to executives economic answers rather than engineering answers. He cited and explained five items in systematic form which he thought should be presented to them for each year of each plan after the evaluation studies suggested by the author had been completed.

L. L. Perry in his discussion of "Interconnections" cited some of the advantages which accrue from the operation of widely interconnected systems, such as lower fixed charges, better operating economy, more uniform frequency, lessened voltage fluctuations, and better service reliability. He also expected that rapid developments with simultaneous automatic frequency-control equipment would be made, and he discussed the use of transformer phase-control equipment.

S. S. Seyfert called attention to the economic and social aspect of interconnections. He cited that the numerous interconnections already effected or in the making have created a new situation calling for a fuller degree of integration than now exists. If the public could be educated as to the advantages and attractive possibilities of interconnection and integration, and if the facts of which engineers are aware could be expressed in their own terms without technical language, the public would be influenced to stand behind and support integrated power systems, financially and otherwise, as they have done for other worthy projects in the past.

INTERCONNECTION—NEW ENGLAND DISTRICT

A. H. Sweetnam described several of the interconnections made with the Boston system. All important transformer banks involved in these interconnections now are equipped for tap changing under load and are supplemented by synchronous condensers. Phase-angle control equipment also is being contemplated. Particular emphasis was placed on one of the points mentioned in the paper: the importance (to the successful operation of any interconnection) of a mutual spirit of cooperation and good will regardless of formal contracts.

H. R. Kurth told of the operating problems of the Boston system in relation to its interconnection, and of some of the mutual advantages which accrue from such operation. Interconnections of ample capacity have permitted operation for maximum over-all economy of the several systems without loss of their corporate identities. In conclusion he stated that the spirit of cooperation between the several system operators is paramount in New England.

ELECTRICAL UNITS

H. B. Brooks discussed "Electrical Units and Their Application." He was in agreement with the author that electrical units should not be arbitrary if agreement with the fundamental units is to be maintained. He also told of a development by Doctor Silsbee to meet the demand in the a-c. field for a new type of instrument. It operates directly on the electrodynamic principle and can be wound as wattmeters, ammeters, or voltmeters, with a reading error equivalent to that of a pointer instrument having about 1,250 scale divisions.

In relation to the part of the paper pertaining to length measurement, H. W. Bearce calls attention to an important step taken in 1927 by the international committee on weights and measures by which a supplementary definition of the meter was set up in terms of light waves.

L. T. Robinson in his discussion of the subject expressed gratitude for the degree of precision attained by the Bureau of Standards in the absolute determination of the ohm. He hoped that some equally satisfactory arrangement might be made with regard to the volt.

H. L. Curtis in a discussion for Doctor Brooks summarized information which will probably be available to the international committee at its next meeting in 1933.

STANDARD CELLS

L. T. Robinson commented on the fact brought out in Eppley's paper that the permanence of standard cells is much more satisfactory than their reproducibility in absolute values. If the absolute value of the ohm and the volt is adopted and if such progress is made with the volt as has been made with the ohm, the only requirement for working reference standards will be their permanence and transportability.

W. B. Kouwenhoven explained a simple, inexpensive, and fairly satisfactory method to reduce variations caused in standard cells by unequal temperature changes. They can be protected with heat-insulating material such as a two-inch layer of cork which gives good results.

H. B. Brooks discussed the use of standard cells and means of comparing them. He expressed favor for the opposition method, by which one actually measures only the small difference between the e. m. f. of the cell under test and that of the reference cell. He explained that he had under design special potentiometer for standard-cell comparisons which is based on the opposition method but has novel features which avoid two small inconveniences of the method, mentioned by Doctor Eppley.

DESIGN OF POTENTIOMETERS

G. Thompson discussed the use of low-resistance and high-resistance potentiometers. He pointed out that it would be a mistake to draw the conclusion from the paper "Design of Potentiometers," by I. Melville, that the high-resistance potentiometer no longer has its place in voltage measurements; or even that it is inherently less accurate and reliable than the low-resistance types. Long experience has shown that gradual changes to take place in the resistance of the slide-wire, due to wear from the sliding contact near the ends of the wire. On the other hand, high-resistance potentiometers have retained their initial accuracy without repair.

H. S. Brooks discussed several points brought out in the same paper. He stated that absolute stability in the coils of a potentiometer is unnecessary; the requirement being that the various coils of any given potentiometer should maintain their relative values to a suitably high degree. In connection with taking account of parasitic e. m. f. by using a false zero setting of the galvanometer, as suggested by the author, he points out that there are cases, such as in the comparison of standard cells, where this method is not reliable.

Doctor Eppley discussed this paper and he believed the author had overestimated the difficulty of making 1,000-ohm coils constant to 0.01 per cent, and that he had underestimated the difficulty of making lower-valued coils of the same consistency. He said that he had known sealed 1-ohm coils, so enclosed as to be protected against humidity changes, action of oil, etc., to vary by more than 0.02 per cent; while on the other hand, he had checked many instruments having 1,000-ohm coils of the ordinary non-enclosed type which remained constant to 0.01 per cent.

N. E. Bonn in his discussion of this subject explained why he takes exception also to the author's discussion of the superiority of the low-resistance potentiometer over instruments having a high internal resistance. He also briefly discussed the modification of the White potentiometer shown in Fig. 6 of the paper. In calculating the maximum errors that may arise from the manipulation of dials and switches, he did not believe the author's assumption that compensation would always remain accurate to 0.01 per cent.

Cables

G. B. Shanklin discussed "Economics of High-Voltage Cable" calling attention to the fact that since the paper was written, there has been a still further reduction in the cost of 66-kv. oil-filled lines. This has been accomplished by a reduction of insulation thickness from 0.40 and 0.42 in. to 0.35 and 0.375 in., representing approximately a 25 per cent reduction in the cost of oil reservoirs, and an increase of from 70 to 75 deg. cent. in guaranteed maximum copper temperature.

W. B. Kouwenhoven discussed this paper with reference to the improvement in power factor with time shown in Fig. 31, and the fall in the ionization factor shown in Fig. 32. He explained that in his work improvement in power factor has been noticed following impregnation, which improvement continued over a considerable time before reaching a constant result. This was accounted for by a lowering of the initial conductivity of the impregnated material, possibly due to absorption of ions by the paper or to some other reason not understood.

W. A. Del Mar discussed this subject and called attention to several points made in the paper. With regard to the lower cost of 66-kv. single-conductor oil-filled cables as compared to the cables of the ordinary type, he pointed out that this conclusion applied only to the flat topography of Chicago. Concerning the simplification of oil-filled cable he believed that shipping-reel reservoirs for cables impregnated with liquid oil at the factory constituted an essential feature.

J. B. Whitehead in his discussion of this subject asked Mr. Roper whether credit for increased stability and life of the oil-filled type might not swing the comparison of the 66-kv. single-conductor cable more definitely to the oil-filled type and perhaps extend the economic oil-filled range even lower in the scale of load and voltage values.

Characteristics of Oil-Filled Cable

D. D. Higgins read a discussion of this subject prepared by K. W. Miller and F. O. Wollaston, which gave reasons why they preferred to solve the oil-flow and temperature-transient problem by well-known methods of elementary differential equations instead of the Heaviside operator used by the authors.

W. A. Del Mar discussed the papers on oil-filled cables and stressed the importance of the high dielectric strength over long periods of time rather than the "breathing" property, explaining how this was attained. In conclusion he indicated the two different methods used by the authors to obtain an open passageway between the reservoir and the hollow core without weakening the joint, and stated that the industry will watch with interest the performance of these two ways of solving the problem.

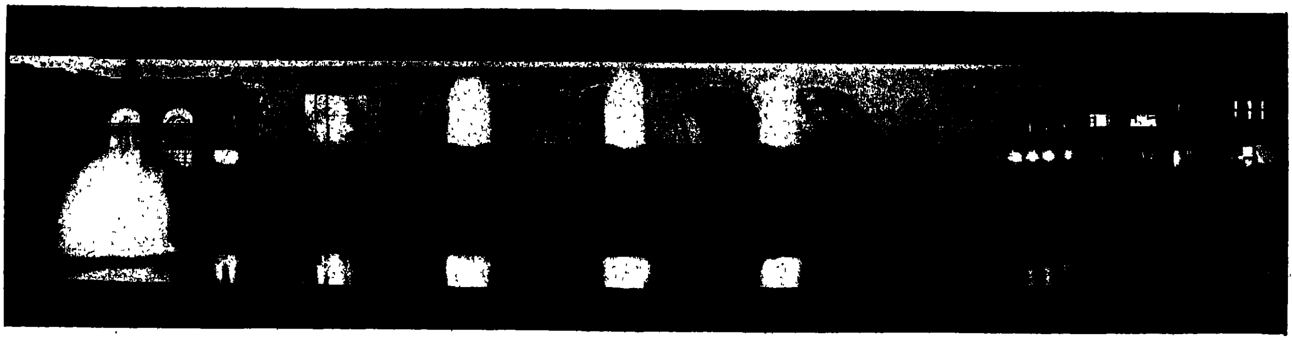
G. B. Shanklin discussed the condenser principle of joint and terminal designs brought out in the paper by Atkinson and Simmons. He believes there are undoubtedly possibilities in the use of this principle. However, to meet existing competition the designs must prove equally good, or better, electrically and mechanically and be of equal or lower cost. Compactness is an important factor to be considered. In his opinion, the condenser principle was more applicable to stop-joints than to normal joints and terminals.

Impregnated-Paper Insulation

G. B. Shanklin discussed the paper on this subject saying that he does not believe the results obtained could be reliably used as a practical guide for factory production methods. He is of the opinion that high vacuum during the drying operations is not the entire answer, as far as the removal of initial factory impurities is concerned.

A part of W. A. Del Mar's discussion in connection with this paper described an investigation made recently by J. H. Palmer showing by means of Lichtenberg figures the effect of corona on test voltage. The results as a whole did not show a definite increase in figure diameter with corona. Deviation from a mean was a maximum at the 60- and 80-kv. points, amounting to 0.04 "and 0.03" respectively, or 3 kv. If the very considerable amount of corona used in these tests had no appreciable effect on the voltage, the shortened cable lives noted by the authors

Spectacular Floodlighting at Wanaque Dam



THIS installation consists of 1,600 ft. of floodlighted dam with a slope of 210 ft. below which five electric fountains play, three of them 35 ft. high and 25 ft. wide studded in red, amber, blue, and green lenses and floodlighted by 36 underwater 1,000-watt projectors grouped twelve to a fountain and two smaller pool fountains 15 ft. high and 10 ft. in diameter, the red, blue, green, and amber lenses floodlighted by ten 500-watt underwater lamps. This is the recently completed Wanaque Dam of the North Jersey District Water Supply Commission, fronting eleven acres of attractively landscaped grounds, the roadway lighted with twelve 1,000-watt projectors effectively mounted on roof corners of the various buildings, the dam itself lighted with fifty 1,000-watt lamps mounted on pump house and service buildings to create an impressive appearance of the eleven massive arches silhouetted against the dark green of the brass beneath them and crowned with the white expanse of the main structure. W. T. Blackwell (A'22) general lighting representative of the Public Service Electric & Gas Company, Newark, N. J. was consulting illuminating engineer in charge for the Commission. (Contributed by G. S. Merrill (M'12) W. T. Blackwell (A'22) Public Service Electric & Gas Company, Newark, N. J., through the A. I. E. E. committee on the production and application of light.)

must be due to some kind of resonance effect.

W. A. Del Mar also read J. H. Palmer's discussion which described the design details of a cable terminal with a reinforced end having a logarithmic flare designed to withstand the higher test voltages.

E. M. Clark's discussion also was read by W. A. Del Mar; several suggestions were offered for consideration. A single stock sample of impregnating liquid of medium viscosity was used for several years, and no deterioration of liquid either in its chemical or physical or electrical properties has been noted. The liquid, however, was protected from light with no special precautions aside from the usual oil drum seal. It was suggested that the authors give further description of the physical and electrical characteristics of the compound which they have used.

H. S. Burd in discussion of this same paper pointed out that impregnation and vacuum pressures used would have to be quite different for cable manufacturing methods where large masses are concerned than where miniature apparatus and small samples are handled. He further indicated methods of improvement for the manufacture of solid types of cable paralleling the improvements in the oil-filled cable.

R. W. Atkinson discussed "Insulation Variability" pointing out that the paper has made the laws of probability conveniently available for use in the study cable insulation. However, in further discussion, limitations of the author's method of attack on practical cases were cited and errors in some of the assumptions indicated.

RESEARCH AND SELECTED SUBJECTS

D. C. Prince discussed "Extinction of Short A-C. Arcs" stating that no mention was made of some prominent arc characteristics, such as the rectifying effect of arcs in general and of metal-vapor arcs in particular. He described phenomena which should tend to explain the marked difference in behavior of low- and high-melting materials noted by the author. He believed the cathode-spot phenomena a predominant role in explaining the behavior of short a-c. arcs.

W. B. Kouwenhoven discussed "A Corona Tube Voltage Regulator" showing that the authors have described a voltage regulator which apparently is quite simple and without moving parts. He asked if it were possible to employ the system for the control of frequency, and requested the authors to give a complete circuit diagram, assuming the source of supply to be a 115-volt a-c. generator driven by a d-c. 230-volt motor.

R. H. Park discussed "Experimental Studies of Arcing Faults" commenting upon the method of measuring voltage. He claimed that with a potentiometer resistance of 500,000 ohms, the instrument itself might have an appreciable effect on the oscillations which develop during the arcing period. Thus the potentiometer may have prevented the occurrence of some of the phenomena which were under investigation.

J. K. Peck in his discussion of this same subject analyzed the results of some tests on a 140-kv. system. Out of eighteen oscillograph operations the highest overvoltages recorded varied from 1.2 to 2.6 times normal peak voltage-to-ground. In no case did cumulative oscillations appear in the voltages during the fault. Oscillation durations ranged from 4 to 112 cycles. A typical oscillogram of one of these faults was shown and it is believed that these records are a valuable supplement to the paper.

COOPERATIVE EDUCATION

W. E. Freeman discussed this subject giving several reasons why it would be undesirable to apply such a system of education to state universities. As influencing difficulties he cited (1) large enrolments where engineering students are given fundamental instruction in other colleges of the university and (2) the usual small-community location of these universities, remote from industry.

S. S. Seyfert discussed the subject inquiring if the courses of the cooperative scheme could not be so planned that the two systems could be economically operated in parallel in a department of moderate size. He also asked about the difficulties encountered when a student desired to transfer from one plan to the other.

D. C. Jackson discussed the subject comprehensively and analyzed the value of the paper. So far as comparative results of the two plans are concerned, he pointed out that because of the many incomparables in the situation it is difficult to draw conclusions. He believes 25 years a suitable period to set up for observation in such educational matters before drawing full, ultimate conclusions.

A. I. E. E. Directors Hold June Meeting at Asheville

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the Grove Park Inn, Asheville, N. C., Wednesday, June 24, 1931, during the annual summer convention of the Institute.

There were present: *President*—W. S. Lee, Charlotte, N. C. *Past-presidents*—R. F. Schuchardt, Chicago, Ill. *Vice-presidents*—H. V. Carpenter, Pullman, Wash.; H. P. Charlesworth, New York, N. Y.; H. S. Evans, Boulder, Colo.; T. N. Lacy, Detroit, Mich.; I. E. Moultrop, Boston, Mass.; W. S. Rodman, Charlottesville, Va.; G. C. Shaad, Lawrence, Kans.; C. E. Sisson, Toronto, Ont. *Directors*—A. E. Bettis, Kansas City, Mo.; F. C. Hanker, East Pittsburgh, Pa.; J. Allen Johnson, Buffalo, N. Y.; A. E. Knowlton, New York, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; E. B. Meyer, Newark, N. J.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y. *National treasurer*—W. I. Slichter, New York, N. Y. *National secretary*—F. L. Hutchinson, New York, N. Y. Also, present by invitation, were: L. T. Robinson, Schenectady, N. Y. *Assistant national secretary*—H. H. Henline, New York, N. Y. *Officers-elect*—C. E. Skinner, East Pittsburgh, Pa.; L. B. Chubbuck, Hamilton, Ont.; W. E. Freeman, Lexington, Ky.; B. D. Hull, Dallas, Tex.; W. B. Kouwenhoven, Baltimore, Md. *Past-presidents*—Dugald C. Jackson, Cambridge, Mass.; P. M. Lincoln, Ithaca, N. Y.; Charles F. Scott, New Haven, Conn.

The minutes of the directors' meeting of May 19, 1931, were approved as previously circulated.

A report was presented and approved of a meeting of the board of examiners held June 5, 1931, and upon the recommendation of that board the following actions were taken upon pending applications: 67 Students were enrolled, 117 Associates and 25 Members were elected, 35 applicants were transferred to the grade of Member, and five to the grade of Fellow.

Approval by the finance committee for payment of monthly bills amounting to $27,132.62 was ratified.

A progress report was presented embodying several recommendations of the special committee on Institute policies which had been appointed in accordance with action taken at the May meeting of the board of directors. (A statement regarding the functions of this committee was published in the July issue of ELECTRICAL ENGINEERING.)

Upon the recommendation of the special committee on Institute policies and with the concurrence of Chairman Kidder of the committee on the engineering profession, a resolution was adopted "that in view of the large number of important matters that would ordinarily come before the committee on the engineering profession, the work should be divided, and the name of that committee should be changed to 'committee on legislation affecting the engineering profession;' also that a new standing 'committee on the economic status of the engineer' should be appointed."

Consideration was given to the draft of a constitution prepared by the electrical advisory committee of the American Standards Association, for an "electrical standards committee," which was proposed by the A. I. E. E. in February 1930 to function as a joint agency in the electrical industry and as an integral part of the American Standards Association, for the purpose of carrying out the standardization activities of that industry. The board voted its approval of the proposed constitution.

The president was authorized to appoint a successor to the late Edward D. Adams as one of the Institute's representatives upon the engineering societies library board.

Recommendations to the board of directors adopted at the conference of officers and delegates held at Asheville, June 22-23, were presented and referred to appropriate committees for consideration.

Upon petition, and with the approval of the chairmen of the Sections and the finance committees, the board authorized the organization of a Montana Section of the Institute.

Consideration was given to a draft of a small pamphlet containing information on electrical engineering for high school students, to assist them in deciding whether or not to prepare to enter this profession, the board at a previous meeting having made an appropriation to cover the cost of printing. It was voted to approve the draft of this pamphlet for printing.

Resolutions were adopted expressing the board's appreciation of the services of the members of the Asheville convention committees; also extending to the newspapers of North Carolina appreciation of the effective publicity given by the press to the Asheville convention.

Other matters were discussed, reference to which may be found in this and future issues of Electrical Engineering.

"American Bells" of Louvain in Summer Concert

The Louvain carillon, of French, English, and American fabrication, and rising 140 ft. above sea level, will celebrate a continuation of the international ceremony by which it was presented July 4, 1928, by a series of concerts during the summer, at which Kamiel Lefavere, Belgian cailloneur of the Riverside Church, New York will officiate. In a letter to Dr. A. D. Flinn, director of Engineering Foundation, Prof. Van Essen, secretary general of the University of Louvain has said, "These bells regulate our academic life as well as that of our citizens . . . through the University's office, they are governing the time-table and occupations of the whole city." Recent appointment of Paul Van Zeeland, professor of economics, University of Louvain, to the American Engineers Memorial Committee has been announced by the Hoover Foundation for the development of the university.

1931 Lamme Medal Nominations Close October 1

In fulfilment of By-Law requirements second posting is hereby given to the necessity of all nominations for the Lamme Medal for 1931 being submitted not later than October 1, 1931. (See Electrical Engineering, June 1931, p. 446.)

Presentation of the 1930 Lamme Medal was duly made to W. J. Foster, consulting engineer, General Electric Company with suitable ceremonies at the opening session of the Institute's recent summer convention, Asheville, N. C.

Library of Congress Available for Wide Service

Collections of matter published in the various branches of science and available for public use in the Library of Congress, Washington, D. C., are far more extensive and comprehensive than seems to be generally understood, according to Dr. H. W. Tyler, consultant in science at that library. Facilities for research by both individuals and groups, a system of inter-library loans, and a card index service covering some 965,000 titles, are among the services available.

In addition to the strictly library service, according to Doctor Tyler there now are seven consultants: one each in science and philosophy, economics, and sociology; and three in literature and history. The function of these consultants is described as "interpretation," and assisting in forming outside contacts with specialists or various authorities in specialized fields. Engineers interested in the possibilities of using the Library of Congress service may obtain information relating to specific fields by corresponding with Doctor Tyler.

A. I. E. E. Lamme Medal Presented at Asheville

In keeping with the established custom the Lamme Medal of the American Institute of Electrical Engineers for 1930 was presented to Dr. William James Foster (F'16) at the summer convention in Asheville, N. C., with appropriate ceremony, Monday morning June 22, 1931. Instead of the custom previously followed of making the presentation in connection with an evening dinner meeting, this year it was made one of the first orders of business at the opening session, an arrangement in keeping with the importance and dignity of the occasion, and meeting with the heartiest approval of assembled delegates. As previously mentioned (Electrical Engineering, March 1931, p. 230 and July 1931, p. 519) the award was made for Doctor Foster's "contributions to the design and development of rotating electrical machinery."

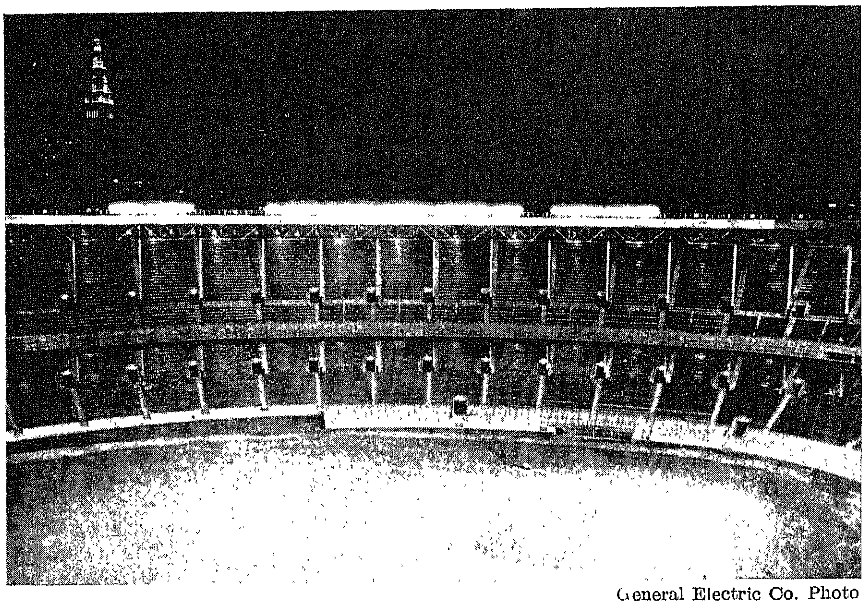
Past-President Charles F. Scott (F'25-HM'29) three-year chairman of the A. I. E. E. Lamme Medal committee and long-term active leader in Institute affairs, presided during the presentation ceremonies. Doctor Scott opened the meeting with a historical sketch covering the life of the founder Benjamin Garver Lamme, and his triplicate bequest to the A. I. E. E., to the Society for the promotion of Engineering Education and to the Ohio State University.

Doctor Scott introduced P. L. Alger, chairman of the A. I. E. E. electric machinery committee, who gave a biographical sketch outlining Doctor Foster's engineering achievements and paying him high tribute, saying, "No one has been more intimately and continuously associated with the development of large electrical machinery during its period of most rapid progress than has Dr. W. J. Foster."

Doctor Scott then called upon W. S. Lee, president of the Institute, to present the medal and certificate to Doctor Foster.

Doctor Foster in his response gave a brief outline of the history of rotating electric machines saying that while "it is possible that the art of designing rotating machines is nearing the climax I see no reason for not expecting still larger generating units. . . . However, it is probable that the outlook for real creative work now is in the line of motors rather than generators."

Cleveland's New Stadium Floodlighted



General Electric Co. Photo

CLEVELAND'S new $3,000,000 municipal stadium, said to be one of the country's best lighted sport arenas, is illuminated by 250 floodlighting projectors each equipped with a 1,000-watt incandescent lamp. These units are mounted along the stadium roof 110 ft. above the ground and arranged to give a normal average intensity of 20-ft. candles over the entire playing field with special provisions for intensities up to 50-ft. candles as required by different branches of sport. In the accompanying night view of one end of the stadium the tower of the new Union Terminal may be seen. Permanent seats are provided for 78,189 spectators.

Shall it be Price or Quality?

Because it reflects a serious condition that by no means is limited to the radio division of the field of electrical apparatus and appliances, and because electrical engineers well can afford to devote serious thought to the problems involved, the following editorial from the July 1931 issue of the McGraw-Hill publication *electronics* is reprinted herewith in full:

"The Blight of Price"

"Radio now faces a new internal competition—the bitter wrangle of price whittling—which is bound to manifest itself as a blight on every part of the industry.

"Former standards of quality are being abandoned in some quarters, in desperate efforts to get prices below competing low standards.

"Conservative factors of safety in set design and set manufacture are being wiped out, and the market is being flooded with receivers which 'just get by'—with prospects of troublesome breakdowns after a few months in the customer's hands.

"Tone quality—a requirement all important if broadcasting is to continue as a dominant musical medium—seems to have been forgotten, in the race to shave costs.

"All along the line, this blight of price is being felt, throughout the trade and industry, and in the associated fields of broadcasting and parts manufacture.

"Makers of components entering into radio sets find that their specifications and prices are being hammered down until price paralysis penetrates even the outermost fringes of parts making.

"Dealers and distributors protest that present low price units give them little on which to operate successful businesses. Broadcasters see the doom of their great new art, if poor radio reproduction is to be the standard,—rather than full fidelity of tone.

"Every group concerned deplores the price situation in which radio finds itself today.

"It is time the radio industry turned about and climbed out of this price morass. Every group is anxious to get back on good firm ground.

"Strong leadership will find an army ready to follow."

"Handbook of Oil Burning" Issued.—Information of practical value to the electrician whose work requires a knowledge of electrically operated oil burners is contained in the new "Handbook of Oil Burning" ($3.00) just published by the American Oil Burner Association, 342 Madison Avenue, New York, N. Y. Besides a thorough treatise on the part played by electricity in the operation of modern oil burning heating or power plants, the book discusses the different oil burner types and principles of construction, oil burner controls and motors, and the wiring of a house or building for an oil burner installation. A wealth of general information such as the fundamentals of heat and heat transfer, the chemistry of combustion and flame, the determination of heating capacity requirements, comparative fuel costs and like subjects is also included. Printed in pocket size for convenience, the new handbook contains 629 pages with 123 tables and 358 illustrations and charts spread over 24 chapters.

I. E. C. Plans for 1932 Paris Congress

The year 1931 represents 50 years of organized international electrical endeavor since that first convention in Paris in 1881, when the principal issue between nations whose delegates were in attendance was a decision on electrical units.

In a desire to make its 1932 congress in Paris particularly momentous the International Electrotechnical Commission has asked its United States national committee to appoint a subcommittee in charge of American participation in this congress. This special committee is now in process of organization; notice of personnel, detail of operation, etc., will be given publicity later. Until more complete plans have been perfected, all inquiries may be addressed to H. S. Osborne, secretary, United States National Committee, Room 1018, Engineering Societies Building, 33 West Thirty-Ninth Street, New York, N. Y.

Lamme Medal Award to C. A. Fieldner

The Lamme Medal award made this year at the Ohio State University was practically in duplicate; it being the first time the ceremony has taken place since the establishment of this special fund. The accumulated amount gave rise to a double presentation.

One of these medals went to C. E. Skinner, president of the Institute, (June, 1931, ELECTRICAL ENGINEERING, p. 524), and the parallel award was made, for like accomplishment—"for meritorious achievement in engineering or the technical arts"—to C. A. Fieldner, chief engineer, U. S. Bureau of Mines, Washington, D. C.

S. A. E. Meeting Discusses Novel Plans

With approximately 700 representative automotive engineers in attendance at its opening session, the summer meeting of the Society of Automotive Engineers convened at White Sulphur Springs, Va., June 14-19, "to solve problems of new designs and increase of production" in automotive industries. Fourteen technical sessions were occupied with subjects such as aircraft, automobiles, the evolution of the Diesel and other automotive engines, Diesel fuels, transportation, the investigation of detonation, the elimination of "vapor-lock," and results obtained by Bureau of Standards research.

Information on the new and unique "tear-drop" automobile body design was presented in a paper by W. T. Fishleigh, consulting engineer of Detroit, and discussed in some interesting detail. The Honorable D. S. Ingalls, Assistant Secretary of the Navy for Aeronautics flew to the convention in an autogiro to be the speaker Thursday evening, June 17, when Dr. G. W. Lewis, of the National Advisory Committee was presiding officer. A diversive program included a water carnival, field day athletics, flying, golf, tennis, archery, and a "grand ball."

Coffin Award Won by Virginia Electric.—The Chas. A. Coffin annual award to "the central station company which has done most for electrical art during the preceding year" was made in June in connection with the 1931 convention of the National Electric Light Association. This award established by the General Electric Company in honor of its founder, carries with it a check for $1,000 to be placed in the winning company's mutual benefit association. The Virginia Electric Light & Power Company received the honor for "increased efficiency of public benefit."

Rear-Mounted Automobile Engine is Predicted

Rear engine mounting for motor cars is a subject which is being seriously considered by the Society of Automotive Engineers. Placing the steering wheel in the center of an automobile and devoting most of the front half to the power plant seems absurd to Herbert Chase, a consulting engineer of New York, who pleads the case for this innovation: "Even a fairly long engine can be placed transversely at the rear of the chassis, and various cylinder arrangements are available that are not feasible for use under a normal hood in front, making the proportional length of chassis occupied by the engine much smaller than in conventional designs.

"Grouping all the mechanism at the rear gives the body designers a free hand; a streamline form becomes possible for the complete vehicle, parts such as lamps and spare tires being enclosed. Larger seating space, a better position for the driver, improved riding-qualities and a saving in weight are held out as objects to be gained by moving the engine from the front to the rear.

"Various forms and arrangements of the mechanical units are available, most of them calling for the engine, transmission and differential in a single, compact unit that is readily accessible and easily adapted for quick removal. Engine cooling and the control connections present two of the more difficult problems."

A. S. T. M. Announces New Officers and Activities

Announcement is made of the following officers of the American Society for Testing Materials for the year 1931: F. O. Clements, technical director, research laboratories, General Motors Corporation, Detroit, president; S. T. Wagner, consulting engineer, Reading Company, Philadelphia, Pa. vice-president; and A. W. Carpenter, manager, testing laboratories, B. F. Goodrich Company, Akron, Ohio, K. B. Cook, technical manager, Manville Jenckes Company, Pawtucket, R. I., J. B. Johnson, Chief, Material Branch, Material Division, U. S. Army Corps, Wright Field, Dayton, Ohio, G. C. D. Lenth, consulting engineer, Chicago, Ill., and O. L. Moore, engineer of tests, Universal Atlas Cement Company, Chicago, Ill., members of the executive committee.

The recently organized International Association for Testing Materials, (W. H. Fulweiler, United Gas Improvement Company, Philadelphia, American representative) holds its first congress September 6-12, 1931. Headquarters will be at the Swiss Federal Polytechnicum, Zurich, Switzerland, and the various countries represented by individuals and by companies will contribute to a technical program divided into four groups: (A) metals; (B) non-metallic organic materials; (C) organic materials; and (D) questions of general importance. Americans, all members of the A. S. T. M. and among them W. A. Slater, research professor of engineering materials, Lehigh University, W. A. Selvig, chemical engineer, U. S. Bureau of Mines, L. T. Work, asst. prof. chemical engineering department, Columbia University and H. F. Moore, professor of engineering materials, University of Illinois, will contribute papers the chief object of the congress being to secure international cooperation, and an exchange of views and experience in all matters incident to the testing of materials. Mr. Fulweiler may be addressed in care of his company or A. S. T. M. headquarters, 1315 Spruce Street, Philadelphia.

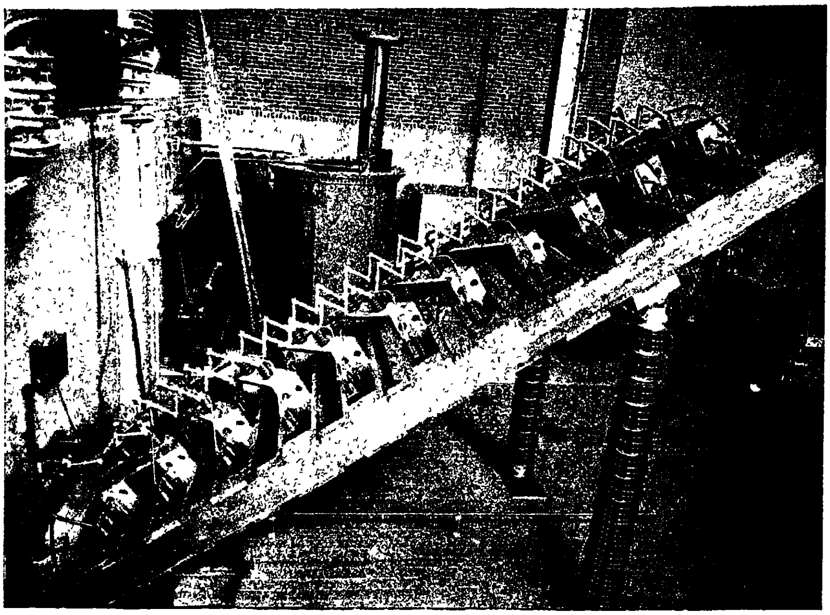
W. L. Saunders Comes to End of Active Life

William Lawrence Saunders, chairman of the board of directors of the Ingersoll-Rand Company, New York, and for most of his 75 years active in engineering and many other fields, died at Teneriffe, Canary Islands, June 25, 1931.

All his life he was ever watchful of opportunities to fill a breach or meet an emergency. As early as the year 1876 while on a newspaper in Philadelphia (perhaps an outgrowth of his having been editor-in-chief of the University of Pennsylvania Magazine, and class poet) he made two balloon ascensions to an altitude of several miles remaining up over night, an evidence of grit and initiative, as were also his courageous experiments in the development of his well-known equipment for rock drilling under water. A warm personal friend has said of him, "He wanted to be in everything, and he got there!"

He was president of his company at the time of its incorporation. During the World War, he was member and then chairman of the Naval Consulting Board, President Wilson giving personal recognition and appreciation of his work. He was past-president of United Engineering Society and of the American Manufacturers Export Association; a fellow of the American Geographical Society; member of the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Mining and Metallurgical Engineers, New York Chamber of Commerce, American Iron and Steel Institute, New Jersey Harbor Commission, and the National Foreign Trade Council; a director of two mining companies and president of *Compressed Air Magazine*. He was a prominent figure in the political life of the State of New Jersey and twice mayor of North Plainfield, his place of residence.

Lightning Generator at Purdue University



FOR studying lightning discharges and their effects upon electrical apparatus, this 1,000,000-volt lightning generator was placed in the engineering experiment station of Purdue University in June 1930. The 44 condensers are charged by subdividing them into eleven parallel groups of four each and applying a d-c. potential of 100-kv. through resistances of 200,000 ohms per bank. Charging potential is obtained from two 150-kv. 250-milliampere kenotrons, and can be varied by means of a full 100-per cent buck or boost regulator connected to the primary winding of the 5-kva. transformer supplying these tubes. The charging apparatus is remote-controlled from a push-button station, while discharge is initiated by a three-electrode and trigger-gap arrangement which makes possible also the synchronizing of a cathode-ray oscillograph with the discharge.

George Washington Bridge (N. Y.-N. J.) to be Well Lighted

Under an arrangement similar to that now in effect in the Holland Tunnel between New York City and New Jersey, the Public Service Electric and Gas Company (New Jersey) and United Electric Light and Power Company (New York) each will furnish half of the electric energy for illuminating the new George Washington Bridge across the Hudson River.

The new span will be lighted by 230 lamps (500-watt each) on 18-ft. standards spaced approximately 90 ft. apart on opposite sides of the roadways. Lights to be serviced by each company will be in staggered arrangement so that if one of the services is interrupted, half of the lights on the bridge still will remain lighted thus providing temporary illumination for the entire length of the roadway. Some 200 lamps (50 watt) suspended from up-stream and down-stream cables, will show these general curves so that at night aviators may avoid them. Because of the width of the roadway at the New Jersey approach, illumination of the bridge will be provided by floodlights mounted on the top of two 100-ft. ornamental towers. On the top of each of the two towers on the bridge there will be installed two Department of Commerce air beacons.

Societies' Library Reports on Service

In recent report, Harrison W. Craver, director of the Engineering Societies Library, states that during the first five months of 1931 there have been added to the library either by gift or purchase, 4,880 books and pamphlets. Of these, 3,030 have increased the main collection which now represents 66,527 titles indexed under 37,100 subjects with 434,326 cards and 135,574 classifications. The budget appropriation for 1931 is $56,653.55. Five months' service record is as follows:

Searches made	42
Articles translated	89
Books loaned to distant members	90
Members served by mail	1,561
Telephone inquiries satisfied	2,553
Number of visitors	12,255
Members served in person	18,726
Photoprints (to 2,136 persons)	21,691
Total, (books and pamphlets)	141,546

So far, the 1931 use of the library shows increase over the 40,000 engineers by whom it was used during 1930.

Dr. Karl T. Compton, president of the Massachusetts Institute of Technology was the recipient of the Rumford Medal, an award made by both the Royal Society and the American Association of Arts and Sciences "for the most important discovery and useful improvement in heat and light." Doctor Compton received it in recognition of his contributions in the field of thermionics by the study of electron emission from hot filaments, and in spectroscopics by the study of matter means of light waves.

Industrial Accident Statistics.—This 1931 edition of the booklet containing a record of injury rates in 28 American industries up to the year 1930, includes compiled from activities of electric railways, automobile production, construction, metallurgical operations and some other less technical occupations. It has just come from the press of the National Safety Council, Inc., 20 North Wacker Drive, Chicago.

Around the World with Light's Golden Jubilee.—An attractive and comprehensive "summary" by the International Committee on Light's Golden Jubilee, containing in alphabetical arrangement by name of country, some 70 pages of cuts and text illustrative of each country's share in this world-wide demonstration, has just come from the publishers. This souvenir booklet has been placed in the Engineering Societies Library, New York, that it may be of ready access to anyone caring to rehearse the pleasures and interest of this epoch-making event—"an extraordinary tribute to a great genius."

Dr. C. M. Slack, research engineer of the Westinghouse Lamp Company, by developing a glass bubble to be used as a window in the Leonard ray tube, won the $500 cash prize offered yearly by the Westinghouse company for "the most important changes either in manufacturing methods or design of a product of the company."

Standards

Graphical Symbols for Electric Traction Proposed

Pamphlet form of a standard proposed for "graphical symbols used for electric traction including railway signaling" (A. I. E. E. Std. No. 17g5) has just become available for suggestion and criticism. This report was prepared by a subcommittee of the Sectional Committee on Scientific and Engineering Symbols and Abbreviations, working under the procedure of the American Standards Committee and sponsored by the Institute and four other organizations. Copies may be had without charge from H. E. Farrer, secretary, Standards Committee, A. I. E. E., 33 West 39th Street, New York, N. Y.

The report is limited to symbols for apparatus generally used for all classes of electric traction and railway signaling, for power houses, substations, transmission systems and distribution systems; electrical equipment of electrically-operated cars and locomotives; and electrical equipment and associated equipment used for railway signaling. In general, these symbols are intended for one-line diagrams of multi-phase a-c. systems, or on complete wiring diagrams of single-phase a-c. and two-wire d-c. systems. Where possible to have these symbols correspond with those in other reports and in other sections of this report, this has been done, but in some cases common agreement could not be obtained. It is hoped, however, that a period of use will bring them into complete harmony.

Engineering Foundation

Foundation Sponsors Publication Program

Initiated by a communication bearing the signatures of the presidents of the four Founder societies and the chairman of The Engineering Foundation, the latter organization has undertaken the publication of a series of articles dealing with various phases of the general subject "has man benefited from engineering progress." The first of these articles introduced by excerpts from the aforementioned communication appears on pages 641-4 of this issue of ELECTRICAL ENGINEERING.

The Foundation's stated aim in this noteworthy project is to "disseminate sound information among the millions of men and women who are vitally concerned" in the hope of "advancing the good of mankind by stimulating resourceful Americans to think their way through the passing months of maladjustment into effective action that will restore our normal state of steadily ascending happiness and freedom." To quote further:

"The Engineering Foundation has requested leaders of thought in many fields to state some of their observations of facts on the benefits which men of our times have obtained through the help of science and engineering. Their answers will be widely published with the intention of making them generally useful in these days when so many persons have had thrust upon their attention the problems of business, economics, social organization, and personal subsistence, which too many persons rarely consider seriously.

"The Engineering Foundation will welcome constructive contributions of additional information or comment from readers of the statements as they appear in newspapers and magazines."

Ambrose Swasey Gives $250,000 More

Another gift, of $250,000, from Mr. Ambrose Swasey (HM' 28) making his contributions total three-quarters of a million, has just been announced by V. N. Dorr, president of United Engineering Trustees, and H. H. Porter (M' 12) chairman of The Engineering Foundation.

At a dinner tendered by Chairman Porter at the University Club, New York, June 30, 1931, at which thirty presidents and former presidents of national engineering societies including the Engineering Trustees and The Engineering Foundation were present, together with other nationally prominent engineers, Mr. Swasey stated that in 1914 he became impressed with the thought that great and far reaching assistance might be rendered by a stimulation of research and development work in the engineering profession. Consequently he was inspired to work for the establishment of The Engineering Foundation, and now, "having a high appreciation of the very practical and helpful results already achieved and believing that the broad and well-laid plans of the Foundation promise even greater service in the future," Mr. Swasey generously makes possible the expansion of these activities by placing in the hands of the United Engineering Trustees this additional fund of $250,000 "for the furtherance of research in science and engineering or for advancement in any other manner of the profession of engineering and the good of mankind."

Mr. Swasey, now approaching 85, survives Mr. Warner in the Cleveland firm of Warner & Swasey, long famous for large telescopes, precision instruments, and machine tools. Doctor Pupin (President '25-'26) has stated that "had it not been for The Engineering Foundation it is quite possible that the National Research Council would not exist" and that therefore "several national problems which men in the united engineering societies, aided by The Engineering Foundation and guided by its ideals, can help to solve" would have had to remain perplexing obstacles to progress.

Personal

Dr. Harris T. Ryan Becomes Emeritus Professor

As of August 31, 1931, Dr. Harris J. Ryan (F'23 and past-president) retires from his long and successful career of active teaching at Stanford University, but in so doing he still retains the dual commission of emeritus professor of electrical engineering and honorary director of the Ryan Research Laboratory. This move is in accord with Stanford's established policy of relieving its professors of active class responsibilities upon the attainment of 65 years of age.

To those who have known and appreciated the diligence and attainment with which Doctor Ryan has labored for the profession, it is gratifying to learn that his plans for the future include a continuation of active research in the field of high voltage where he is looked upon as a worthy authority. For more than a decade his work has pioneered its way through obstacles in the path of electrical progression, and his realizations in connection with electrical application have eclipsed even the hopes of many men of science and the profession. In training his students for their specific work his principle has been always that any researches undertaken should be for maximum value to the engineer in the field; and in the founding (1926) of the Ryan High-Voltage Laboratory at Stanford University, reward for his untiring efforts, in the practical and consistent application of his principle was given concrete form.

His contributions to technical literature are well-known; men of such organizations as the National Academy of Science, The American Physical Society, the American Association for the advancement of Science and others of similar importance representing science, engineering, and industry, have done him homage in friendship as well as in professional relationship. Doctor Ryan's whole career exemplifies fine achievement, cooperative spirit, cordial personality, and unusual ability of execution.

R. A. Millikan (M'22) whose discoveries in the realm of physics have made of him an international figure, has been named to return the visit of Professor Einstein. Only a short time ago Doctor Millikan was introduced to his radio audience by President Hoover, who designated him as "more than a physicist—one of America's leaders in philosophic thought." Recently also he was one of six notable physicists to receive first awards from a $1,000,000 trust fund established by Gustav Oberlaender, manufacturer of Reading, Pa., "to enable mature American citizens to study in Germany" and "increase understanding and good will between the people" of the two countries.

Ralph Kelly (A'12) southwestern district manager of Westinghouse Electric & Manufacturing Company, has just announced the appointment of L. S. Washington (A'19) as manager of the company's northeastern section, and that of E. D. Stewart (A'12) as manager of the southwestern section of his district. For the past several years Mr. Washington has been syndicate representative for Westinghouse in St. Louis and a member of the St. Louis Electrical Board of Trade. Mr. Stewart's new work gives him complete charge of company activities in the Houston, Dallas, San Antonio, and El Paso offices and respective territories.

C. L. Proctor (A'08) since 1925 vice-president and general manager of the Toledo Edison Company, an office which he holds also with the Lake Shore Power Company and the Toledo and Indiana Railroad Company, is now president of the east central division of the National Electric Light Association. He already has served in its midwest and southern divisions as a member of its executive committee. The Oklahoma Utilities Association and the Kansas Utilities Association also lay claim to him in like capacity.

J. A. Darling (A'21) assistant chief system operator, Edison Electric Illuminating Company, Boston, Mass. has been made chairman of the Operators' Association of New England. In token of his extended service with the company he was the honor guest at a complimentary dinner and the recipient of a 30-year service pin and Telechron clock with Westminster and Canterbury chimes from the Company.

H. E. M. Kensit (M'08) after 15 years in the Dominion Civil Service retired August 1, 1931, to enter private practise. Mr. Kensit is a member of the Engineering Institute of Canada and of the Association of Professional Engineers of Ontario. He joined the Institute in 1908 as an Associate but immediately advanced to the grade of Member.

C. H. Champlain (A'28) for the past eight years manager of the Westinghouse works at Sharon now has been made works manager at East Pittsburgh; while A. B. **Raynders** (A'07) in addition to his present duties as works manager, East Springfield, Mass., will assume supervision of operations at the Mansfield, O.

Charles M. Burrill (A'25) who has been broadcast receiver development engineer for the R. C. A. Victor Co., Inc., Camden, N. J., has gone to Ontario, Canada, to become research engineer for the Rogers-Majestic Corporation, Ltd. Mr. Burrill is 1930-31 chairman of the I. R. E. subcommittee on high-frequency receivers.

E. T. Moore (F'21) president of the Power Control Corporation of Syracuse, N. Y., is in Mexico where he will supervise the first installation of his invention the power demand limitator in a Mexican mine at Chihuahua. Later he plans to go to Mexico City, and thence to San Francisco, Los Angeles, Seattle, Salt Lake City, and points in Arizona.

W. M. Abbott (M'22) chairman of the board of directors of the Illinois Bell Telephone Company, on May 1, 1931, at the annual meeting of the Chamber held at Atlantic City received reelection as vice-president of the Chamber of Commerce of the United States for the Northern Central Division.

Frank Thornton, Jr. (F'21) manager of residence engineering, general engineering department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., has been chosen manager of the company's association activities to succeed R. W. E. Moore (M'17) recently resigned.

Frank J. Meyer (M'17) assistant to the general manager, in charge of operation, Oklahoma Gas and Electric Company, Oklahoma City, Oklahoma, now has become its vice-president in charge of operation. Mr. Meyer is chairman of the Institute's Section in Oklahoma City.

Stanley Stokes (F'29) assistant vice-president of the Union Light & Power Company, St. Louis, Mo., has been appointed consulting engineer for that company and its subsidiaries. This new office will permit him to devote his entire attention to major engineering matters.

R. W. Allen (A'23) who has been acting in the capacity of distribution engineer for the South County Public Service Company, Westerly, R. I., recently accepted like position with the New England Power Engineering and Service Corporation, Providence, R. I.

G. F. Chellis (M'16) manager of Ferranti, Inc., New York, N. Y., has severed his connections with the American organization to accept a position with the Whitehall Securities Company, London, England, where he will be associated also with the English Ferranti Company.

Harry Reid (A'22) president of the National Public Service Corporation and the National Electric Power Company, New York, N. Y., and for more than 25 years prominently identified with electric light and power industries, now becomes vice-president of the N. E. L. A.

T. H. Morgan (A'23) has resigned from the office of assistant professor of electrical engineering, Stanford University to become head of the department of electrical engineering at Worcester Polytechnic Institute, Worcester, Mass.

H. T. Edgar (M'28) for the past 32 years associated with Stone & Webster in managerial work throughout the country as a division manager, after 45 years of service in the public utility field has resigned.

W. H. Bliss (A'30) graduate assistant in electrical engineering, Michigan State College, East Lansing, Mich., and designer and constructor of the "Telomat," is now instructor in electrical engineering there.

George Brock (A'19) draftsman for the Edison Electric Appliance Company, Pomona, Calif., has received promotion to the position of cost reduction engineer for his company.

Ralph A. Watson (A'08) consulting engineer of Champaign, Ill., is now on his way to Russia as consulting engineer for Arthur McKee & Company, of Cleveland, Ohio.

W. H. Taubert (A'29) has been placed in charge of sales in the insulation division of the Corning Glass Works, and is removing from New York City to the company's home office at Corning, N. Y.

Obituary

Edward G. Acheson, (M'88 and Member for Life) chairman of the board of the Acheson Oildag Company which he himself founded, died at the home of his daughter New York City July 6, 1931, of pneumonia. As a scientist and inventor he was known internationally and was the recipient of many medals and honors both here and abroad.

He was born at Washington, Pa. in 1856 and passed his youth in the manner of the average country boy, with no particular inclination toward the classics but most pronounced fondness for mathematics. In his first position as time keeper at a blast furnace in Monticello, Pa., he was permitted considerable time for mechanical pursuits, and at the age of seventeen was granted his first U. S. patent on a rock-boring machine. The financial depression of 1874 closed the blast-furnace and Mr. Acheson was compelled to engage in non-technical labor until 1877 when he secured a position with the Alleghany Valley Railroad, which ultimately led to the work of tank gager in the Bradford oil fields. Irregularities of construction at that time greatly complicated capacity calculation, so Acheson promptly set about constructing a set of tables whereby the content of any tank could readily be determined. His efforts however did not meet with the approval of a superior whose business it was to calculate these capacities, and Acheson was dismissed. He entered the service of the Pittsburgh Southern Railroad as assistant to a surveying party; advances in electricity stirred his imagination and in a desire to become actively engaged in what was then a new industry, in 1880 he sought and obtained a position as draftsman with Thomas Edison at Menlo Park. Fortunately for him he was not confined closely to the drafting table but allowed to indulge his inventive genius and in 1881 he produced a graphite loop filament for the preparation of which he received the prize of $100 offered by Mr. Edison. Under date of January 8, 1889 he presented his first paper before the A. I. E. E. on the subject of *Lightning Arresters and a Photographic Study of Self-Induction.* Perhaps one of his greatest contributions to commercial science was his discovery of a new chemical compound produced electrically at the power plant of the Monongahela Electric Light Company which he founded in 1890. While working on the reduction of iron ore, he noticed that clay objects placed within the furnace became impregnated with carbon and as a result, much harder. Experimenting with similar clay-carbon mixtures, he produced a new chemical compound, silicon carbide, commercially known as carborundum. As it was hard enough to surface a diamond, it found ready market with jewelers and the Westinghouse company promptly placed a $7,000 order for 60,000 grinding wheels.

William F. Smith (M'27) assistant superintendent of power, Pacific Electric Railway Company, Los Angeles, Calif., passed away at his home in that city June 14, 1931. He was a native of the state of Missouri (1875) and was educated in the Santa Cruz high school and the correspondence school of Scranton, Pa. From 1894 to 1897 he was occupied with construction and operating work for the Santa Cruz Electric Railway; the next several years were engaged in construction and car house work. He was in charge of the installation of multiple-unit equipment of the North Shore Electric, Sausilito, Calif. and also reconstructed some operations of the Power Development Company, Bakersfield, Calif.; in fact most of his work has been construction and remodeling, including the Central Station of the Los Angeles Railway Company and all high-voltage work in all the stations of the Pacific Electric Railway. His Membership in the Institute dates from 1905, when he joined as an Associate.

Truman P. Gaylord (M'21) acting vice-president of Westinghouse Electric & Mfg. Company, with which he had been connected since 1900, died suddenly of heart disease at the home of his mother in Shelby, Mich., the place of his birth February 15, 1871. As a preparatory school for his later training, he attended the Allen Academy of Chicago, later to enter the University of Michigan, from which he was graduated with a degree in electrical engineering. In 1895 he secured a second degree from Armour Institute of Technology at which he held an associate professorship in electrical engineering 1894-98. The World's Fair at Chicago was starting and Mr. Gaylord engaged with the Fair company as engineer of underground construction, continuing in that capacity until 1893. From 1898 to 1899 he was engineer for the Chicago Edison Company, and July 1899 took his first position with the Westinghouse Electric Company. In 1902 he was appointed its district manager with offices in Chicago, a position which he occupied until he became acting vice-president, August 1914. By the board of directors of the Pittsburgh Chamber of Commerce he was recently elected president; also he was director and member of the executive committee of the Pennsylvania State Chamber of Commerce, and member of the United States Chamber of Commerce, the Duquesne Club of Pittsburgh, and the Pittsburgh Athletic Club. He was in charge of the radio division of the Westinghouse Electric & Mfg. Company, remained active and was apparently in good health up to the day of his death. He joined the Institute in 1902 as Associate.

H. G. Specht (M'23) consulting engineer for Westinghouse Elec. & Mfg. Company, Springfield, Mass., died May 17, 1931. He was a native of Farmsen-Hamburg, Germany (1876) and as a young man served several apprenticeships with German manufacturing interests, among them the Machine Company of Grotkast & Kespohl at Wandsbeck and the Electric Mfg. Company of Klamberg at Hamburg. During the year 1896-97 he was in military service in the Engineering Corps at Berlin after which he studied mechanical and electrical engineering for two years at the university in Braunsweig, Germany. His next work was one of design for steamship and dredging machines in the city engineering department at Hamburg. Continuing his electrical engineering study, in January 1902 he graduated from the University in Karlsruhe with his E. E. degree. His work with Westinghouse dates from 1903, when he came to America and joined the East Pittsburgh office, where his work was chiefly test and the development of test curves in the dynamo test department. By 1905 he was designing special induction motors of all sizes and types. His paper *The Synchronous-Repulsion Motor—A Special Development for the Photophone* formed an integral part of the program at the North Eastern District meeting of the A. I. E. E. held at Springfield, Mass., May 7-10, 1930. His membership in the Institute was endorsed by such men as President C. E. Skinner, B. G. Lamme, C. F. Scott, P. M. Lincoln, and B. A. Behrend, all outstanding in the history of the Institute.

C. M. Rosewell (M'21) electrical engineer, Western Electric Company New York, N. Y., died at the Fairmont Private Hospital, Jersey City, N. J. June 2, 1931. He was 47 years of age and a graduate of the State University of Kentucky, from which he received his degrees in both mechanical and electrical engineering respectively 1908 and 1911. During the summer of 1908 he was operating engineer in charge of the plant of the Jackson Electric & Hydraulic Mfg. Company, Jackson, Ky.; the following year he spent in the test department of the Bullock Electric Company, Cincinnati, Ohio. From 1909 to 1913 he continued his test department work with the General Electric Company in Schenectady, advancing each year, from the test department to d-c. motor and generator design engineering, to central station engineering in the lighting department, to central station engineering and commercial engineering. In 1918 he was appointed engineer of the Appalachian Power Company in charge of practically all of the company's engineering. Bespeaking energy and ambition, while he was regularly busy during the week with other duties he engaged for special Saturday night service as night operator of the General Electric's power house switchboard; he also substituted for the superintendent at the Appalachian Power Company when that executive was off duty. He joined the Institute in 1919 as an Associate but in 1921 was transferred to the grade of full Member.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Bunce, Lewis I., Rocky Hill, Conn.

Cartwright, Kenneth C., Haig Hotel Annex, 2548 Prospect St., Cleveland, Ohio.

Cole, Will G., Box 222, Westwood, Calif.

Corrivbax, F. M., General Electric Co., Schenectady, N. Y.

Deacon, L. O., 6 Ailsa Ave., East Malvern, Melbourne, Australia.

Haggerty, John J., 2849-33rd St., Astoria, N. Y.

McLean, James S., 190 Old Army Road, Scarsdale, N. Y.

Nuber, Frank J., 3831 Rokeby St., Chicago Ill.

O'Shea, V., Jr., 115 Broadway, New York, N. Y.

Pistorius, L. H., 193 Jeppe St., Johannesburg, South Africa.

Prudham, W. M., 100 Biddle St., Wilkinsburg, Pa.

Sullivan, John E., 6320 Kenmore Ave., Chicago, Ill.

Tung, C. T., c/o Stone & Webster Engg. Corp., Hopewell, Va.

Past Section Meetings

Portland Section Meets With O. S. C. Branch

The annual spring joint meeting of the Portland Section and the Oregon State College Branch was held at the college May 23, 1931; attendance 100.

Following a dinner, four technical papers were presented by students:

A Bridge Method of Testing Welds, by J. R. Batcheller.

Weld Strength as Indicated by Relative Conductivity, by Glen Barnett.

Influence of Preservatives on Dielectric Strength of Wood, by C. B. Parsons and M. H. Tiplon.

Moisture Content of Wood and Its Relation to Electric Permittivity, by O. E. Boucher and Hamilton Howell.

Cleveland

Annual dinner meeting at which W. S. Lee, president A. I. E. E., and consulting engineer and president, W. S. Lee Engineering Corporation, Charlotte, N. C., spoke on Doing a Common Thing in an Uncommon Way. Election of officers: G. A. Kositzky, chairman; F. E. Snell, secretary. May 21. Attendance 77.

Columbus

Rhythmic Ramblings through Our National Parks, by Dean Alfred Vivian, Ohio State University. Election of officers: W. L. Everitt, chairman; Roy Mallory, secretary-treasurer. May 28. Attendance 15.

Detroit-Ann Arbor

Golf tournament followed by dinner, Election of officers: Joseph J. Shoemaker. chairman; Raymond Foulkrod, vice-chairman; Oscar E. Hauser, secretary-treasurer. June 20. Attendance 43.

Kansas City

Annual banquet. The Inductive Relations between Power and Telephone Lines, by A. T. Campbell and C. C. Yates, both of the Southwestern Bell Telephone Company. Election of officers: George Fiske, chairman; R. M. Ryan, secretary-treasurer. May 29. Attendance 93.

Madison

Machines, by Prof. C. M. Jansky, University of Wisconsin. Demonstrations at the electrical laboratories followed this talk. Election of officers: Norman H. Blume, chairman; G. F. Tracy, secretary-treasurer. June 3. Attendance 44.

Toledo

Institute Affairs and Activities, by E. C. Stone, The Philadelphia Company, and vice-president, District No. 2, A. I. E. E. Election of officers: J. A. Dinwiddie, chairman; Max Neuber, secretary-treasurer. June 12. Attendance 34.

Urbana

Audible Light, by John B. Taylor, General Electric Company, Schenectady, N. Y. May 26. Attendance 200.

Vancouver

Dinner. Election of officers: G. R. Wright, chairman; C. Arnott, secretary. June 8. Attendance 25.

Worcester

Inspection trip through the Tewksbury substation of the New England Power Association. June 13. Attendance 20.

Past Branch Meetings

University of Colorado

TRANSMISSION CONSIDERATIONS IN CHAIN BROADCASTING, by R. C. Giese, American Tel. & Tel. Company., Denver, Col. May 20. Attendance 45.

Election of officers: Fred W. Cooper, chairman; Sidney Larson, vice-chairman; Wendell C. Spear, secretary, John F. Drescher, treasurer. May 28. Attendance 45.

College of the City of New York

Election of officers: Alexander Rosenberg, chairman; Robert G. Herzog, vice-chairman; I. E. Lawlor, secretary; L. Milstein, treasurer. May 28. Attendance 18.

Lewis Institute

Inspection trip through the Chicago office of the Western Union Telegraph Company. June 12. Attendance 18.

Southern Methodist University

Election of officers: J. V. Melton, president; M. P. Jones, vice-president; Porter Lindsley, secretary-treasurer. June 2. Attendance 8.

Washington State College

Election of officers: D. H. Olney, president; Howard Stingle, vice-president; G. C. O'Brien, secretary; G. Bliesner, treasurer. May 21. Attendance 17.

Employment Notes

Of the Engineering Societies Employment Service

Men Available

ELECTRICAL ENGINEER, 1931, single, 22, available immediately. Desires position in any electrical line with opportunity for advancement. Salary moderate. Has had some experience in public address systems. Location preferred, New York vicinity, but will consider others. C-9432.

GRADUATE ELECTRICAL ENGINEER, 22, single, B. S. in E. E., 1931. One and three-fourth years of practical experience with leading elevator company. Desires position with manufacturing or utility company. Location optional. Excellent references. C-9474.

GRADUATE ELECTRICAL ENGINEER, 1930, single, six months on Westinghouse engineering course covering tests on switchboards, circuit breakers, regulators, motors, generators, etc. Nine months supervising telephone conduit and cable plant construction and telephone cable testing. Excellent physical condition. Desires permanent position with a good future. Location, immaterial. C-9158.

SALES EXECUTIVE ENGINEER, electrical and mechanical training. Seven years' sales experience in bearing field, three years' sales engineering in application of bearings to electrical, mechanical, and automotive fields, four years' in sales management, promotion, and distribution. Would like opportunity to develop or direct sales. C-5431.

PYROMETER ENGINEER, 25, christian, single. Graduate E. E., extension course of Columbia University. Five years' experience as field engineer for well-known manufacturer of industrial instruments. Experienced in construction, application, and selling of pyrometers and automatic valves. C-8647.

GRAUDATE ELECTRICAL ENGINEER, 24, single, B. S. in E. E.; midwest university. One year of G. E. Test. Will consider position offering engineering experience. Location immaterial. Available immediately. C-9451.

GRADUATE ENGINEER, executive and consulting. Degrees E. E. and M. S. in engineering. Licensed professional engineer, New York State; 25 years' electrical-mechanical experience, design, operation, maintenance of power plants, industrial plants, modern production and plant operation. Combustion and heating, air cooled gasoline motors, heat transmission. Available now. B-8170.

GRADUATE ELECTRICAL ENGINEER. B. S. in E. E., 1931, intends to study for M. S. degree at night; 21, single. Desires position in any electrical engineering field including radio or vacuum-tube work. Available at once. Location, New York preferred but not essential. C-9467.

ELECTRICAL ENGINEER, graduate A. I. T., 24, married; eighteen months large utility company previous to college; three summer vacations as laboratory technician for radio condenser manufacturer; one year in electrical maintenance for self. Excellent references. Will accept minimum living salary with reliable concern. Go anywhere except Russia. C-8668,

EXECUTIVE AND GRADUATE MECHANICAL-ELECTRICAL ENGINEER; twelve years' experience in public utility, industrial, and marine fields. Specialized in plant management, economic studies, organization, and power plant design and operation. During the last four years supervised the expenditure of $10,000,000 for public works projects. C-9416.

ELECTRICAL ENGINEER, technical college graduate, 35. Ten to twelve years' mechanical and electrical experience in power plants, substations, and transmission and distribution systems. Work includes G. E. Test and public utility engineering and operation. Desires position on operating staff of power company. Location, not particular. B-9782.

GRADUATE ELECTRICAL MECHANICAL ENGINEER, University Budapest, Hungary; 41, American citizen. Research and development engineer with largest electric companies along manufacturing and insulating electric conductors. Expert knowledge of sound recording. Besides English, speaks German, French, Italian, Spanish, Hungarian. Desires position where also linguistic knowledge useful. Location preferred, California. C-2505.

1931 TECHNICAL GRADUATE of midwestern college, B. S. in E. E. 24, single. One year student engineer on G. E. test. References furnished. Available on two weeks' notice. C-9497.

ENGINEER EXECUTIVE, B. S. degree. twenty years' experience in engineering, contracting, and purchasing. Desires permanent connection with large industrial company or as a local representative. Location, New York City. B-5050.

TELEPHONE ENGINEER, married, 38; eleven years' experience, installation, building, equipment, and traffic engineering. Specialist on automatic equipment problems. Experience covers all types of telephone equipment. In addition to English speaks Scandinavian languages, German, and Spanish. Location immaterial. C-9532.

MECHANICAL ELECTRICAL ENGINEER for mines, or plant engineer for steel mill or allied industry; 42 years old, technical graduate, twenty years' experience. B-8653.

TELEPHONE ENGINEER, 38, married, university graduate, Lieut.-Col.-Officers' Reserve Corps; eleven years Bell System equipment engineering, five years' varied experience in Philippines and Orient. Consider anything offering opportunity for advancement. Specially qualified in planning and supervising economical and efficient provision of customers' telephone facilities. B-9568.

ELECTRICAL ENGINEER, E. E. degree, 36, single, desires position with public utility or engineering concern requiring executive ability and an analytical mind. Fourteen years' experience covering engineering, design, and valuation of power plants, substations, transmission and distribution systems. Available immediately. Location preferred, East. C-9570.

WIRE AND CABLE SALES ENGINEER, graduate electrical engineer who has specialized in electrical wire and cable engineering. Fifteen years represented public utilities and consulting engineers writing specifications, supervising manufacture, expediting, inspecting at manufacturer's plants, supervising installations. Experienced cable engineer for technical sales department of wire and cable manufacturer. B-3625.

GRADUATE ELECTRICAL ENGINEER, B. E. E. degree 1930, 24, single. Eight months on Westinghouse course. Assignments covered motor apparatus testing and refrigeration development work. Desires position with manufacturing concern or public utility. Working knowledge of Spanish. Initial salary and location secondary to opportunity. Reference. Available on short notice. C-9428.

GRADUATE ELECTRICAL ENGINEER, 23, B. S. in E. E. 1929, M. S. in E. E. 1931 from Massachusetts Institute of Technology. General Electric Test experience. Experienced in the design of motors and generators. Available on short notice. Location immaterial. C-9559.

GRADUATE ELECTRICAL ENGINEER, 27, single. Seven years' experience in supervising and laying out of electrical construction work in various industrial plants and buildings. Desires position as superintendent or electrical engineer with contracting or industrial firm or municipality. Available at once. C-9553.

ELECTRICAL-MECHANICAL ENGINEER, 39, married. G. E. student course. Eighteen years' experience sequence-motor-control systems, industrial engineering, sales, patents, investigations and reports, machinery development. Prefers connection as industrial consultant or as sales engineer. C-9552.

GRADUATE of five-year cooperative school, 22, single, B. S. in E. E. in 1931. Eighteen months' experience in the installation and engineering department of a public utility. Desires a position in any electrical line with future and an opportunity for advancement. Available at once. Location immaterial. C-9545.

ELECTRICAL ENGINEER, graduate German technical institute, 31, single. Two and one-half years with German railroad camp in maintenance of rolling stock, two years' practical experience in repair work on freight and passenger cars with American railroad camp and two years electrical inspector. Desires position with railroad camp. C-9519.

ELECTRICAL ENGINEERING GRADUATE desires position as junior engineer with public utilities concern in power plant operations or as junior engineer with construction company specializing in power plant and transmission line construction. Has had two years' experience in power plant construction and operation. C-9406.

ELECTRICAL - MECHANICAL ENGINEER, 31, married, five years' experience with American concern telephone equipment sales in United States and South America, two and a half years radio, movietone, amplifying equipment sales and installations as branch manager in Central America for European manufacturer. Speaks and writes five languages fluently. References. Available immediately. C-9558.

GRADUATE of five-year cooperative school in electrical engineering, 24, speaks Spanish and English fluently, one-year study of production methods and five years' of street railway experience, desires position in any state or nation. Location immaterial. C-9002.

ENGINEERING GRADUATE, 39 years old. Broad experience in design, construction, and operation along both electrical and mechanical lines. Willing to go to any location. Excellent references. B-5471.

ELECTRICAL ENGINEER graduated 1928, 27, married. Has civil engineering and over two years' Westinghouse test course experience. Location immaterial. Now employed by manufacturing corporation. Desires position with a future. C-9568.

ELECTRICAL ENGINEER, 1931 graduate B. S. degree in E. E. from the University of Illinois, 23, single, American. Six months' experience in the engineering department of Illinois Bell Telephone Company. Some experience Thyratron tubes, photoelectric cells. Desires position engineering company, consulting engineers. Location, anywhere in United States, Canada. C-9582.

ELECTRICAL ENGINEER, B. S. and E. E. degrees. Nine years' experience in development and production of static condensers for radio, ignition, and power-factor applications. Some work with X-ray and power-amplifier tubes and associated apparatus. B-9250.

ERECTING ENGINEER, 46, of broad experience in power plant construction, maintenance, and operation. Exceptional ability in the erection and wiring of switchboards, power plant auxiliaries, oil circuit breakers, and high-voltage outdoor substations. Available immediately. C-8702.

GRADUATE ELECTRICAL ENGINEER, age 28, married, with eight years' experience in industrial plant construction and maintenance; railway electrification; power plant design, estimating, and construction. Supervisory experience on construction and costs with contractor. Desires position with utility, manufacturer, or contractor, where ability to handle labor and produce results is a prerequisite. C-4428.

ELECTRICAL ENGINEER, B. S. in E. E., 1927, single, 20 months' experience in design and testing of fractional-hp. motors; two years' manufacturing experience. Familiar with a-c. and d-c. motor and control application. Desires electrical engineering work. Location, immaterial. C-9168.

TECHNICAL GRADUATE, 31, married, eleven years' experience on steam and hydroelectric systems as operator and system operator. Desires position as load dispatcher or system operator. Location, immaterial, but West Coast preferred. C-7267.

INTERNATIONAL OR DOMESTIC BUSINESS, university graduate, 31, thoroughly trained and experienced, seven years' engineering and business United States and abroad; export, power system planning, developments, reports, estimating, organizing; foreign languages, German, Spanish, some French. Desires connecting holding company or trade; will consider representing concern abroad. Available short notice. Personal interview desired. C-3534.

ELECTRICAL ENGINEER, university graduate, 36, married. Background of eight years' experience electrical testing in field and laboratory, also in erecting equipment. Additional three and one-half years' experience in testing and manufacture of radio tubes. Desires position with manufacturer or laboratory. Location preferred Metropolitan New York. Available now. B-8817.

ELECTRICAL-MECHANICAL ENGINEER. Executive. Twenty-three years' diversified experience as an engineer and executive in industrial plant equipment and operation. Particularly successful in present connection along lines of mechanical plant improvement and in obtaining employee cooperation through personnel training. Can refer freely to each connection held. C-7839.

GRADUATE ELECTRICAL ENGINEER, 31, single, eight years' experience, design, and construction of transmission lines, voltages up to and including 220 kv., outdoor and indoor high-voltage substation and distribution networks. Desires position in engineering or construction department of large utility or holding company. Location immaterial. C-3564.

GRADUATE ELECTRICAL ENGINEER, University of Wisconsin, 32, single. Three years' Westinghouse Test. Seven years' supervision, power plant and transmission line construction. Eight years engineer inspector, purchasing, writing specifications, and expediting. Desires position with advancement and opportunities. Location, immaterial. Available August. B-9661.

RELAY ENGINEER, university graduate, ten years' practical experience, thoroughly familiar with all relay applications and testing, short-circuit studies, stability calculations, and all problems connected with system disturbances. Moderate salary. Available at once. C-9291.

GRADUATE ELECTRICAL ENGINEER, 1930, single. One year's experience in test, design, and development of small fractional- and integral-hp. motors. Previous experience with public utilities. Now employed. Position must be permanent and promise a good future. Location a secondary factor. C-9590.

ELECTRICAL ENGINEER, college graduate, married, five years' electrical apparatus design, fifteen years supervisor, high-voltage overhead transmission and distribution lines, substations, estimating design and construction, test field experience. Nine years' practical machine shop. Desires responsible position. C-9257.

ELECTRICAL ENGINEER, 21, single, B. S. degree in E. E., Texas A. & M. College 1931, holder of government broadcast class operator's license. Two years' experience in radio work. Desires position in radio or telephone industries. Available at once. Will go anywhere. C-9588.

ELECTRICAL ENGINEER, 23, single, graduate of five-year cooperative course. Did electrical construction work during course. Desires position with power company, engineering, or contracting firm. Location immaterial; Midwest preferred. Available immediately. C-9586.

1928 GRADUATE ELECTRICAL ENGINEER of recognized university, 26, single. Wishes employment where the following engineering experience may be used to advantage. One year power company test experience, 20 months as special apprentice on large electrified railroad, six months' radio and telephone experience. C-9112.

GRADUATE ENGINEER, B. S. in E. E. from Northern college of cooperative type; 23, single; cooperative experience; six months' production engineering in radio division of Westinghouse; six months power, local cabling drafting, including student course Western Electric; one year student engineer at Weston Electric Instrument Company; excellent references; location immaterial; available two weeks' notice. C-9599.

ELECTRICAL DRAFTSMAN, DESIGNER, five years' experience, supervisory control, wiring diagrams, plant, pole-type metering equipment, building, factory lighting, power plant layout including contracts sales, etc. Experience covers fifteen years wireless telegrapher, a-c. and d-c. motors, generators winding, shop test, repair man for all electrical equipment, lineman, meterman, switchboard repair man, power plant electrician. B-8984.

EXECUTIVE ENGINEER, 31, unmarried, graduate of outstanding engineering institution. One year of postgraduate study and teaching with record in executive capacity. Experienced on communication engineering, telephone, telegraph, radio, sound, television, etc. Speaks several foreign languages. Location, immaterial. Available immediately. C-696.

ENGINEER, Stevens graduate, one and one-half years G. E. Test, with broad knowledge of transmission operation gained during five years with public utility operating in the foreign field, seeks new connection, either domestic or foreign. Would be valuable for the staff of general superintendent being mechanical engineer with electrical experience. C-9177.

GRADUATE ELECTRICAL ENGINEER, 25; two years' experience in power system operation, system planning and development; also experience in distribution and transmission engineering. Desires position in any location with public utility, or in any electrical line offering a future. Available upon short notice. References. C-9281.

ELECTRICAL ENGINEER, 23, single, graduate Georgia School of Technology B. S. degree in E. E., Cooperative Plan 1930; five years' experience railroad shops all departments during cooperative course; one year's experience electrical utility, all branches. Desires position with utility or manufacturing concern. Prefers Southeast. C-9292.

ELECTRICAL ENGINEER, 22, single. E. E. degree, 1929; M. S. in E. E. from M. I. T., 1931; twenty months G. E. Test course. Desires position involving electric design and development. Location preferred, East. Available immediately. C-9462.

GRADUATE ELECTRICAL ENGINEER, 31, married, with seven and one-half years' experience including: 2½ years as engineer with manufacturer's service shop, two years university instructor, two years responsible position in manufacturer's engineering department and one year as electrician on station construction. Desires position with manufacturer, industrial concern, public utility. Available upon short notice. C-1073.

SECRETARY ENGINEER, as assistant to major executive or for promoting publicity with progressive manufacturing r railway industry. Good correspondent. Alert, industrious, reliable, courtous, pleasing, yet forceful personality. Holds B. S. and E. E. degrees from leading institution. Two years' graduate work engineering, business administration. Six years' experience research, development and testing. C-930.

ELECTRICAL ENGINEER, recent graduate, 23, E. E. at Rensselaer Polytechnic Institute; desires engineering work with opportunity for advancement; would like work in communication engineering or radio-tube engineering fields. Location, New York City. C-9605.

Instructors

M. I. T. GRADUATE ELECTRICAL ENGINEER, 35, married. Six years' industrial and teaching experience in electrical engineering. Several years' private research and development work on own initiative. Good ability, integrity, and personality. Desires university teaching position for life work. Location preferred, Middle West or South. C-2826.

PROFESSOR OF ELECTRICAL ENGINEERING, 40, six years' successful experience teaching practically all branches electrical engineering, state school. Considerable experience power, telephone work. One year switchboard engineering department of Westinghouse. B. S. in E. E. and E. E. degrees. Preferred location Rocky Mountains, Pacific Coast States. Available school year 1931-1932. C-5021.

PHYSICIST, middle-aged, experienced in industrial research, supervision of research, executive work and teaching physics for engineering and other classes of students. Advanced degrees in physics from prominent American universities. Emphasis of electrical subjects in training and teaching. Stability and opportunity desired. Available upon short notice. C-7900.

SUPERINTENDENT OF DISTRIBUTION, 43, married, electrical and industrial management. Twenty years' electric utility operating experience in engineering, construction, operation, maintenance of distributing and transmission lines, substations, first-aid, and educational work. Has sufficient public utility operating experience to qualify for position of superintendent. Demonstrated record of executive ability. C-8411.

GRADUATE ELECTRICAL ENGINEER, 25, obtaining Master's degree in June, 1931, desires position as assistant professor or instructor in electrical engineering or as research engineer. Four summers' employment with large utility company. Two years' teaching experience. Has had experience with development of remote-control apparatus. Location, United States. C-8994.

GRADUATE ELECTRICAL ENGINEER, 24, two years' manufacturing experience. Desires position on university staff with opportunity to work on Master's degree. Available September. C-9157.

GRADUATE ELECTRICAL ENGINEER, 23, B. S., M. S. in E. E., desires position, instructor in engineering department of college, university. Has fundamental, practical knowledge d-c., a-c. circuits and machines. Can teach engineering mathematics, physics. Has had some experience teaching, two years research work obtaining degrees. Location, anywhere in United States. C-9214.

ELECTRICAL ENGINEER, 1931 graduate of Colorado University, desires position as junior engineer, sales engineer, or instructor in mathematics or electrical engineering subjects. Has had eighteen months' practical work in electrical service and repair of power equipment prior to college. Location, Southern or Western United States. C-9241.

JUNIOR ENGINEER, 1930 graduate, B. S. degree in E. E., associate member of Sigma XI. Eight months' practical experience in research, design, and testing with large radio concern. Desires position as engineering instructor or in any electrical line offering a future. Eastern location preferred. Salary secondary to opportunity. C-9300.

ELECTRICAL ENGINEER, 28, A. B. E. E. 1926. Two years as emergency man, one year as engineering assistant with a New

York power company. Four years with a telephone company making studies of equipment and operating conditions and on service maintenance. Two years teaching mathematics in evening classes. References. C-9308.

ELECTRICAL ENGINEER, 1930 graduate, 22, single. One year on the Westinghouse student course. Desires position as instructor in electrical engineering. Available school year 1931-1932. References. Location, immaterial. C-9311.

ELECTRICAL ENGINEER, B. S. degree, married, with about fifteen years' successful experience in the design and construction of transmission and distribution lines. Some teaching experience. Employed at present. Desires position as instructor in electrical engineering subjects or physics and mathematics. Excellent references. Location preferred, Middle West or West. C-9339.

ELECTRICAL ENGINEER, 30, married. A. B. '22; B. S. in E. E. '24. (Harvard.) G. E. Test, transformer design, development and technical writing; experience in factory planning, has taught evening classes. Speaks German. Location preferred, East. C-9402.

ELECTRICAL ENGINEER, 1931 graduate from a southern technical institute, desires part or full time position as instructor in mathematics or electrical engineering, with the privilege of carrying graduate work. C-9415.

TEACHER OF ELECTRICAL ENGINEERING, 37, marrried. Thirteen years' teaching experience, many summers spent in practical work. B. S. in E. E. and E. E. degrees. Taught all E. E. subjects, as well as physics, electric thermodynamics, descriptive geometry, mechanical drawing. Sixteen months' general management large college radio station. Available immediately. C-9445.

ELECTRICAL-MECHANICAL ENGINEER, 1931 graduate with experience in central-station equipment testing. Desires position teaching in capacity of instructor or as research engineer to continue with education leading to Master's degree. C-9461.

ELECTRICAL ENGINEER, 22, single. E. E. degree, 1929. M. S. in E. E. from M. I. T., 1931. Twenty months', G. E. Test. Desires position involving electric design and development or as instructor in E. E. Location preferred, East. Available immediately. C-9462.

RECENT COLLEGE GRADUATE, B. S. in E. E., 22, single. Desires position with electrical concern or as instructor in mathematics and electrical engineering. Some maintenance experience. Location preferred, East. C-9406.

INSTRUCTOR, electrical engineer, 31, with nine years' experience with utilities, contractor, consulting engineer, and manufacturers, wishes position as instructor for electrical and mechanical engineering or drafting, mechanics, etc., in trade schools, high schools; speaks and writes German and French. Good references. C-4758.

ELECTRICAL ENGINEER, graduate University of Illinois, 1926. Two years' experience with Westinghouse Elec. & Mfg. Company, two and a half years with public utility in planning division. Available immediately. C-9381.

GRADUATE ELECTRICAL ENGINEER, Lehigh University, 1930, married, 25, ten months' engineering graduate student at Westinghouse, and 22 summer months with National Tube Company. Desires position with public utility of manufacturing company where analytical and research ability is prime prerequisite. Available upon two weeks' notice. Location, East or Middlewest. C-9395.

ELECTRICAL ENGINEER, graduate 1931, single. Three years' cooperative experience in public utility maintenance work. Four summers' experience in ice-cream industry. Desires opening offering steady work and possibility of advancement. Location and type of work secondary. Available at once. C-9418.

GRADUATE ENGINEER, B. S. in E. E., 1928, 25, single. Fifteen months' G. E. Test course, including six months in vacuum-tube-department. Sixteen months' development engineering of electrical aircraft instruments, control devices, and naval ordinance control. Also some testing laboratory experience. Available at once. Location preferred, East. C-9483.

MECHANICAL-ELECTRICAL ENGINEER, B. in M. E. and E. E. and Master degree in E. E. General Electric Test. Fifteen years' broad experience teaching, research, development, designing, and manufacturing plant management. Position desired teaching mechanical, electrical, or industrial engineering subjects; or part time teaching and management of university plant. Location, immaterial. C-4440.

GRADUATE ELECTRICAL ENGINEER, B. S. in E. E. 1929, single, 24. Twenty-one months' Westinghouse Test on rotating machinery and control apparatus. One year of advanced physics at Carnegie Tech. night school. Desires position as instructor in engineering subjects. Eastern location preferred. C-8966.

ELECTRICAL ENGINEER, B. S. in 1929 from M. I. T. Desires connection to teach engineering subjects. Practical experience in the paper-making and insulated-wire business as an industrial engineer. Able to handle men. Locate anywhere. C-9331.

GRADUATE ELECTRICAL ENGINEER, 24, B. S. in E. E. Knowledge of design, construction of indicating instruments; also knowledge of electron tube. Two year cooperative course with Weston Electrical Instrument Corporation. (32 departments including shop, office, and engineering work.) Three years' industrial work before college. Available immediately. Location, United States, Canada. C-9585.

ASSISTANT PROFESSOR INSTRUCTOR, 39, Cornell graduate, two and one-half years' teaching experience; will bring to the faculty first-hand knowledge of the latest practise in industrial work. Thoroughly familiar with practical requirements for design and installation of mechanical and electrical equipment for industrial plants, power stations, and boiler houses. A-3702.

1929 GRADUATE ELECTRICAL ENGINEER, 25, single. Fourteen months G. E. Test course including thorough experience with illuminating equipment. Also experienced in electrical maintenance, construction in manufacturing plant. Desires electrical, illuminating engineering position with future manufacturing utility company, or teaching position. Prefers Middle Western or Eastern location. Available at once. C-9560.

ELECTRICAL ENGINEER, M. I. T. graduate, with practical experience in design, construction and teaching, author of reference books in electrical and mechanical engineering, is open for teaching position. Well qualified to take charge of engineering and general courses such as mathematics, physics, drawing practical electricity, etc., in vocational and preparatory schools. B-4022.

ELECTRICAL ENGINEER, with Master's degree, desires position of professor of E. E. at a progressive university. Age 34, married. Five years with large electrical manufacturer, three years teaching electrical engineering and four years electrical engineer of an electric utility company. Available upon reasonable notice. C-1118.

RESEARCH AND DESIGN OR INSTRUCTOR, transportation field, manufacturer operating company or technical school. Five years' experience Westinghouse Electric design, manufacture and installation of control apparatus for electric cars and trolley coaches, and research and development on transportation problems. Graduate, University of Wisconsin, 1926. Age 29, single, Protestant. C-9475.

GRADUATE ELECTRICAL ENGINEER, western university, age 26. Two years with public utility company, one year's experience assistant instructor in large university in E. E. department. Operating experience with electric railroad and two years' experience in engineering professional photography. Wishes location in engineering or teaching fields. Excellent references available. Location immaterial. C-9525.

ELECTRICAL ENGINEER, B. S. degree in E. E. 1925. Two years' experience switchboard design, two years' industrial control, two years' teaching experience. Natural talent for teaching. Desires teaching position in engineering college. Location preferred, Middle West or West. C-9577.

GRADUATE ELECTRICAL ENGINEER, class 1929, age 26, single, nine months on Westinghouse graduate student course, thirteen months on transformer design. Desires position in engineering department of public utility or instructor of electrical engineering and mathematics. Location, Middle West or East. Available upon short notice. C-9549.

ASSISTANT PROFESSOR OF ELECTRICAL ENGINEERING, three years' research training and advanced study. Two years' teaching experience. Background of American and foreign utility work. Research and patents in high voltage insulation. Specialties, hydroelectric generation, transmission, radio and communication theory, transients. Best references regarding health, personality, and teaching ability. Location, immaterial. C-9813.

ELECTRICAL ENGINEERING GRADUATE, inexperienced, but with a sincere interest in teaching as a career wishes a position as instructor in electrical engineering, mathematics or physics in college or technical school; mathematics or physics in secondary school. Age 26, single. C-9205.

MECHANICAL ENGINEER, Purdue graduate, many years' experience in boiler work from fireman to plant engineer and manager of boiler shop. Interested in opening with power company or engineering department of industrial company, or with plate or structural shop. Experienced business manager and executive. Will consider teaching mathematics or structural design. B-5551.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.	205 West Wacker Drive	31 West 39th St.
San Francisco	Chicago	New York
N. D. Cook, Manager	A. K. Krauser, Manager	W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

Membership

Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before August 31, 1931.

Appel, I., New York City Board of Transportation, New York, N. Y.

ORDER FORM FOR REPRINTS OF FULL PAPERS ABRIDGED IN THIS ISSUE OF *ELECTRICAL ENGINEERING**

(August 1931) Number	Author	Title
☐ 31-13	J. H. Blankenbuehler	An Improved Arc-Welding Generator
☐ 31-17	F. B. Bramhall	Telegraph Transmission Testing Machine
☐ 31-40	J. B. Whitehead	The Conductivity of Insulating Oils
☐ 31-41	K. K. Palueff	Effect of Transient Voltages on Power Transformers—III—Non-Resonating Auto-Transformers
☐ 31-46	J. B. Whitehead and W. B. Kouwenhoven	Fundamental Properties of Impregnated Paper
☐ 31-47	H. H. Race	Some Electrical Characteristics of Cable Oils
☐ 31-63	F. C. Hanker (Chairman Subject Committee on Grounding)	Present Day Practise in Grounding of Transmission Systems—Second Report of Subject Committee on Grounding
☐ 31-66	G. Sutherland and D. S. MacCorkle	Burn-Off Characteristics of A-C. Low-Voltage Network Cables
☐ 31-74	C. L. Dawes and W. M. Goodhue	Equivalent Circuits of Imperfect Condensers
☐ 31-83	P. H. Moon	The Theory of Thermal Breakdown of Solid Dielectrics
☐ 31-95	J. B. Whitehead and F. Hamburger, Jr	Residual Air and Moisture in Impregnated-Paper Insulations—III
☐ 31-99	M. C. Holmes	Insulation Variability—Its Influence in Determining Breakdown Voltages
☐ 31-124	H. H. Skilling	Tuned Power Lines
☐ 31M2	S. B. Clark	A-C. Networks in Portland, Oregon
☐ 31M3	C. F. Green	Electrical Solutions of Problems of Regular Scheduled Flight

*Members, Enrolled Students and subscribers are entitled t one complete copy of any paper abridged if it is requested within one year from date of its publication in Electrical Engineering. Thereafter a charge of twenty-five cents per complete copy will obtain.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at hte Engineering Societies Library, New York, during June are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

Business Administration. By W. Wissler. N. Y., McGraw-Hill Book Co., 1931. 897 pp., diagrs., charts, tables, maps, 9 x 6 in., cloth, $5.00.——An interesting, readable presentation of the various factors that affect the problems which confront the administrator of business enterprises. Money, markets, men, machines, materials and methods are examined, and their relations to each other are discussed. A critical inquiry into the nature and ends of business as a complex institution aims to show executives where business stands today and the line along which it is developing.

Electric Clocks. By F. Hope-Jones. Lond., N. A. G. Press, 1931. 261 pp., diagrs., 9 x 6 in., cloth, 12s. 6d.——A combination historical and technical account of the evolution of the electric clock. Starting with Alexander Bain's patent of 1840, the author describes and criticizes the efforts of successive inventors and illustrates the steps that have led to the highly accurate devices of today. Numerous diagrams add to the usefulness of the book.

High-Speed Internal-Combustion Engine. By H. R. Ricardo. Lond. & Glasgow, Blackie & Son, Ltd., 1931. 435 pp., illus., diagrs., charts, tables, 10 x 7 in., cloth, 30 s.—A thorough analysis of the scientific basis of design, based upon extensive research and experimentation. General principles, rather than specific designs, are discussed in this important work, which will interest every designer. This is a new edition of the second volume of the internal-combustion engine. The principal change is the addition of a chapter on the high-speed Diesel engine.

Logic of Science. By Harold R. Smart. Lond. & N. Y., D. Appleton & Co., 1931. 237 pp., 9 x 5 in., cloth, 8 s 6 d.——A systematic discussion of the problems that lie on the borderland between science and philosophy, which endeavors to show what scientific concepts have to contribute to the philosophic problems of existence, value, mind and reality, and to apply the logical principles developed by philosophy to the discussion of scientific ideas. The aims and scope of natural science are examined, the relation of each science to its neighbors is shown, the emergence of the major problems is traced, and the proposed solutions are indicated.

Metallkeramik. By F. Skaupy. Berlin, Verlag Chemie, 1930. 60 pp., illus., diagrs., charts, 10 x 6 in., paper, 6-r. m.——This little book is the first to describe systematically the manufacture of articles from powdered metal by molding and sintering it. The preparation and properties of powdered metal and of articles made from it are first described generally. The manufacture of wire, sheet and molded articles from powdered tungsten, molybdenum, tantalum and other infusible metals is then treated. This is followed by a section on carbaloy and similar hard alloys. An appendix discusses some other possibilities of the process.

Principles of City Planning. By K. B. Lohmann. N. Y., McGraw-Hill Book Co., 1931. 395 pp., illus., diagrs., charts, maps, 10 x 6 in., cloth, $4.00.——Aims to give, in a single volume, an account of the whole subject of city planning. The elements and principles of the various branches are presented, and such general matters as the scope and importance of the work, its possibilities and the means of its accomplishment are discussed. City planning in the United States is stressed. Both the design of new cities and the improvement of existing ones are considered.

Relativity. By M. Palmieri. Los Angeles, Cal., Forbush Publ. Co., 1931. 87 pp., 11 x 8 in., cloth, no price indicated. ——A brief non-mathematical presentation of the theory of relativity, intended for lay readers who wish to understand its principles and consequences.

Die Werkstoffdämpfung bei Dreh- und Biegeschwingungsbeanspruchung. (Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, Heft 335.) By O. Föppl and G. Schaaf. Berlin, VDI-Verlag, 1930. 27 pp., charts, diagrs., 12 x 8 in., paper, 4.50-r. m.——Presents the results of an investigation of the damping properties of various metals when subjected to different stresses. Tests of each metal were made by different methods and compared.

Jet-Wave Rectifier. (Ingeniorvidenskabelige Skrifter, A Nr. 24). By J. Hartmann. Kobenhavn, Danmarks Naturvidenskabelige Samfund, 1931. 300 pp., illus., diagrs., charts, tables, 11 x 7 in., paper, price not given. (Published in English.)——This is a mechanical rectifier based upon a principle invented by Mr. Hartmann in 1907. Between the years 1919 and 1929 he was actively engaged in developing the apparatus for high-power rectification. We have here a detailed account of the work done during this period and of the results that have been attained, both experimentally and in practise. The rectifier is quite distinct in character from the mercury-arc rectifier but may be used for similar duties.

Mitteilungen aus den Forschunganstalten Ghh-Konzern, Bd. 1, Heft 3, pp. 45-68, February 1931. Berlin, V.D.I. Verlag, 12 x 8 in., paper, 3-r. m.——Four investigations are reported: the effect of surface condition upon the durability of various steels: a critical investigation of the standard method for dynamic tests; recent advances in welding and cutting cast iron and cast steel; and the measurement of fluids in motion by means of nozzles.

Patent Law for Chemists, Engineers and Executives. By F. H. Rhodes. N. Y., McGraw-Hill Book Co., 1931. 207 pp., 8 x 6 in., cloth, $2.50.——This book, written for engineers and business men, discusses the questions of interest to men engaged in technical and administrative work. The law of patents, the requirements for a patentable invention, the rights that a United States patent confers, and similar general matters are explained and illustrated by citations from court decisions.

Industrieöfen, v. 2. Bau und Betrieb. By W. Trinks. Berlin, V. D. I. Verlag, 1931. 398 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, 20-r. m.——This is the final volume of the German translation of the valuable book on industrial furnaces, the original of which is well-known to American engineers.

Royal Technical College Journal, Glasgow, January, 1931, Vol. 2, Part 3, pp. 371-566, paper, 10 x 7 in., 10s 6d.——Describes work in the fields of chemistry and engineering. Among the subjects investigated were the magnetostriction of overstrained materials, th transmission of heat in a fluid in turbulent motion, the rotating wheel with disk of constant stress ratio, pressure strains in non-circular drums, the influence of direct and shear stresses on the end constraints of curved bars, a standard of roughness for steam nozzles, torsional rigidity and web torque of crankshaft units and the effect of journal clearance, heat transmission coefficients for superheated steam, fuel pipe effects in mechanical-injection oil engines, the lubricating properties of mineral, vegetable and fatty oils, the wave form of the mercury-arc power rectifier, and the radiant efficiency and heat distribution of electric fires.

Underground Systems Reference Book. By National Electric Light Association. N. Y., The Association, 1931. 377 pp., illus., diagrs., charts, tables, 12 x 9 in., $4.00.——A number of leading American authorities has assisted in editing this description of accepted practise in the design, construction, and operation of underground systems of electric distribution. Cables and their insulation, conduit and manhole design and construction, cable installation, splices and terminals, cable operation, miscellaneous equipment and safety practises are discussed in detail. A bibliography of over 4,000 references is appended to the report.

Annual Survey of American Chemistry, vol 5, 1930. Edit. by C. J. West. N. Y., Chemical Catalog Co., 1931. 629 pp., diagrs., tables, 9 x 5 in., cloth, $5.00.——A concise summary of the progress in pure and applied chemistry made in America during 1930. This valuable review contains much to interest engineers, especially in the sections upon the X-ray examination of metals, the metallurgy of iron and steel, water, sewage, cement and concrete, coal, petroleum, gaseous fuels, and paints. The references to sources are very extensive and complete.

Selected Items From

Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Alloys

MAGNETIC. Nickel-Iron Alloys and Their Application to Instrument Construction, F. E. J. Ockenden. *Jl. Sci. Instruments*, vol. 8, no. 4, Apr. 1931, pp. 113-117, 3 figs. Investigation into magnetic properties of nickel-iron series has resulted in production of new class of magnetic materials, these materials having characteristics which render them superior to more usual silicon steels when used at inductions of less than 5,000 lines per sq. cm.; composition giving highest possible initial permeability is very closely 78 per cent nickel, 22 per cent iron; magnetizing and core loss curves. Bibliography.

MAGNETIC—HIPERNIK. Permeability of Hipernik Reaches 167,000, T. D. Yensen. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 386-388, 8 figs. To give electrical engineer data from which he can judge or calculate relative advantages obtainable by using hipernik, representative curves are given for hipernik and for 4 per cent silicon iron.

Alternators

COOLING. Systéme de protection pour alternateurs ventilés en circuit fermé (Protective Devices for Alternators with Circulating Air Ventilation), E. Haveaux. *Science et Industrie*, vol. 15, no. 208, May 1931, pp. 220-222, 4 figs. Review of increasingly severe conditions that high capacity turbo-alternators have to withstand and reasons why closed circulation ventilation is more and more applied; deficiency of actual protective devices in event of accidental failure in supply of air cooling water; simple device adapted to Valenciennes power plant alternators which, while consuming no auxiliary power, automatically converts ventilation into open circuit circulation.

Arcs

On the Theory of the Mercury Arc, K. T. Compton. *Phys. Rev.*, vol. 37, no. 9, May 1931, pp. 1077-1090, 4 figs. Theory of heat balance at cathode is extended by introduction of accommodation coefficient of neutralized ions, by evaluation of all processes which absorb energy gained by electrons in cathode fall space, and by correction of previous assumption that fields sufficient to extract electrons will affect heat of neutralization of positive ions at surface.

Potential Drop and Ionization at Mercury Arc Cathode, E. S. Lamar, and K. T. Compton. *Phys. Rev.*, vol. 37, no. 9, May 1931, pp. 1069-1076, 4 figs. By means of movable Langmuir collector, potential, ion concentration and electron temperature were measured at various distances from stationary mercury cathode spot, at various arc currents; results indicated cathode drop of 10.0 volts, and small negative potential gradient beyond fall space which was more pronounced at larger currents.

Cables

SHEATHS. Cable Sheath Damage and Protection. *Nat. Elec. Light Assn.—Pub.*, no. 127, May 1931, 17 pp., 17 figs. 35 operating companies contributed information on operating experiences; recent trend is indicated toward use of combination of asbestos and cement fireproofing; corrosion damage by d-c. electrolysis due to stray currents is in most cases being effectively combatted; much corrosion has been found in "green" concrete ducts due to chemical action of hydroxides in cement; remedial actions are suggested.

UNDERGROUND. Oil Reservoirs and Accessories for Underground Cables. *Nat. Elec. Light Assn.—Pub.*, no. 119, May 1931, 12 pp., 19 figs. Companies using oil reservoirs in which air or gas is in contact with oil under pressure report satisfactory operation; various types of reservoirs manufactured have proved satisfactory; some companies have found some of bellows type reservoirs to have rather short, useful life; in few cases, accessories and fittings have become defective in service.

Circuit Breakers

Fundamentals the Essence in Circuit Interruption, J. D. Hilliard. *Elec. World*, vol. 97, no. 18, May 2, 1931, pp. 809-811, 1 fig. Phenomena in oil circuit breakers are admittedly complex, but clarity will result if fundamental happenings in all types of breakers are segregated from those which make one type behave differently from another and even one model from another of same general type; much of confusion surrounding subject of circuit interruption results from failure to recognize common elements of all methods of circuit breaking as distinct from factors introduced by variations in design.

The Expansion Circuit Breaker, F. Kesselring. *Elec. Rev.*, vol. 108, no. 2791, May 22, 1931, pp. 859-861, 12 figs. Underlying principles; characteristic curves showing breaking distance; abiadatic expansion; entropy; saturated water-vapor pressure temperature; circuit rupture oscillograms; transportable wall-mounting, and outdoor types of expansion circuit breakers; illustrated comparison as to size between expansion and oil breaker chambers.

Conductors

IRON AND STEEL PLANTS. Conductors of Heavy Alternating Currents, D. I. Bohn and H. W. Pabst. *Iron and Steel Eng.*, vol. 8, no. 6, June 1931, pp. 253-256, 7 figs. Design data and curves for heavy a-c. conductors in steel mills; it is desirable to limit conductor temperature rise to 3 deg. cent., largely to assist in maintaining reasonable temperatures of connected equipment; pipe size of tubular copper and aluminum conductors with capacities for 30-deg. cent. rise at 60 cycles; channel conductor ratings for pairs of aluminum channels arranged to form square, temperature rise 30 deg. cent. over 40-deg. cent. ambient, at 60 cycles.

Dielectrics

Dielectric Properties of Matter, S. O. Morgan. *Bell Laboratories Rec.*, vol. 9, no. 10, June 1931, pp. 462-469, 7 figs. Molecular study, it is shown that methane is symmetrical and therefore non-polar; that in non-polar molecule centers of opposite charge coincide, in polar molecule they do not; potential applied to polar substance tends to shift its molecules from their random orientations; tetrachloromethane is symmetrical and therefore non polar, etc.

BREAKDOWN. Breakdown Voltage as a Function of Electrode Area and Dielectric Homogeneity, M. O. Holmes. *Franklin Inst.—Jl.*, vol. 211, no. 6, June 1931, pp. 777-779. If number of samples of insulation, all apparently similar as regards composition, thickness and area, are subjected to breakdown tests made under identical test conditions, they will not all fail at same value of voltage but, due to inherent inhomogeneities in composition of individual samples, will show variations in breakdown voltage; number of tests made in samples of unit area; voltage distribution of results represented is analyzed.

Education

ILLUMINATING ENGINEERING. Educational Training in the Lighting Art, P. S. Millar. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 5, May 1931, pp. 415-423. Paper was prepared at request of committee which organized present symposium on training for lighting work; it puts forward writers view that scope of lighting art is so broad that it requires of successful practitioner, a comprehensive acquaintance with fundamentals of science and of art with broad cultural background; without discussing in detail procedure in lighting education, it offers suggestion that models may be employed advantageously in such training.

Electric Drive

IRON AND STEEL PLANTS. Electrical Auxiliaries in Steel Mills, D. W. Dean. *Iron and Steel Engr.*, vol. 8, no. 6, June 1931, pp. 199-208, 9 figs. Successful steel plant of future will be one that maintains well planned program for improvements in their auxiliary drives, as well as for their main drives below 30 hp.; matter seems of minor importance, but when we consider that total investment in electrical auxiliaries usually exceeds total investment in main drives it becomes apparent that careful consideration is justified.

How to Get the Most Out of Control in Steel Mills, P. B. Harwood. *Maintenance Eng.*, vol. 89, no. 6, June 1931, pp. 294-296, 3 figs. Requirements for maximum service are select control designed to meet conditions of installation; apply proper motor and control for drive; install equipment properly; maintain it adequately.

LOOMS. The Individual-Motor Loom Drive as Viewed Today, W. A. Mayor. *Textile World*, vol. 79, no. 24, June 13, 1931, pp. 32-33, 3 figs. Advantages of individual drive.

OIL WELL PUMPING. Electrical Installation of Motors and Transformers, E. L. Spaugh. *Oil Weekly*, vol. 61, no. 4, Apr. 10, 1931, pp. 39-41 and 44, 5 figs. Notes on equipment of Rio Bravo Oil Co., in Guffey, Humble, Luling, Pierce Junction and Saratoga oil fields; outline of approved practise; motor housing, foundation, and installation; transformers; power lines for pumping circuit; lighting circuit; general maintenance; hazards of electrical work.

Electric Equipment

IRON AND STEEL PLANTS. Electrical Developments Committee Report—1930-1931, W. H. Burr. *Iron and Steel Engr.*, vol. 8, no. 6, June 1931, pp. 233-240, 12 figs. During year 1930, 109 main roll drives of 300-hp. or over were installed as compared with total of 201 during previous year; total hp. in main roll drives installed during year was 158,440 as compared with total of 313,000 during previous year; charts showing installed power in various types of mills.

Electric Power

BUILDINGS. Tradition Broken with All-Electric Building, H. T. Crane. *Elec. West*, vol. 66, no. 5, May 1, 1931, pp. 228-232, 17 figs. New headquarters of Southern California Edison Co., Ltd., embody practical application of electricity for all requirements of modern office structure; complete building equipment designed for 100 per cent utilization of electric energy; system and equipment is described.

LUMBER INDUSTRY. Electric Power in the Lumber Industry, A. H. Onstad. *Timberman*, vol. 32, no. 7, May 1931, pp. 36-39 and 42, 9 figs. Highly specialized applications of motor drives evolved for western sawmill and logging service; review of specific application of electric power and equipment.

Elevators

ELECTRIC. Miniature Elevator Enters the Home, C. C. Crispen. *Elec. Jl.*, vol. 28, no. 6, June 1931, p. 379, 4 figs. Latest device for household, called "Inclinator," is traveling car or chain mounted on roller truck running in steel channel alone one side the stairway; when not in use platform and two seats fold up in single movement against metal back, requiring only five in. of space; car designed for vertical ascent is used when stairs are winding.

Engineering

A Half Century of Electrical Engineering, C. F. Scott. *Engrs' Soc. West. Pa.—Proc.*, vol. 47, no. 4, Apr. 1931, pp. 224-225, 16 figs. Historical review of development; conditions 50 years ago; electricity in steel industry; mining and transportation; communication; electricity supplants muscle, skill, and judgment; tools, methods, and men; data regarding electrical development; new industrial revolution; problems created by electricity; chronological review of telephone with special reference to Pittsburgh district.

INFLUENCE ON CIVILIZATION. The Engineer—His Part in Present and Future Civilization, S. S. Arentz. *Professional Engr.*, vol. 16, no. 5, May 1931, pp. 4-6. It is claimed that, just as engineer is leader in bringing about mass production, and invention of labor-saving devices, he can with equal effect bring about solution of problems that must be solved in order to eliminate repetition of such times as world is passing through today. Before Am. Assn. Engrs.

Engineers

What the Engineers Are Doing, A. D. Bailey. *Elec. World*, vol. 97, no. 24, June 13, 1931, pp. 1146-1147. As our industry develops, as our service expands in its present fields and extends into new, technical details involved and problems to be met are bound to increase rather than to diminish both in number and importance; engineers will be needed who not only possess high technical qualifications but who are blessed with ambition and imagination as well; men who are trained to analyze and to think straight. Before Nat. Elec. Light Assn. Annual Convention.

Gages

PIEZOELECTRIC. Piezo-Electric Gage and Amplifier, R. A. Webster. *Franklin Inst.—Jl.*, vol. 211, no. 5, May 1931, pp. 607-616, 7 figs. Pressure gage was designed and built using cartridge of pure bakelite; within this was placed pile of 21 quartz crystals, each 0.69 in. sq. by 0.053 in. thick, they being separated by platinum electrodes; screwed brass ends held them in cartridge which was then sealed with beeswax; 3/8-in. piston bore upon this pile; this gage has given very good service and although few of crystals cracked, no loss in sensitivity has been noticed.

Galvanometers

SUSPENSIONS. Note on Julius Suspensions, M. J. Brevoort. *U. S. Bur. Mines—Report of Investigations*, no. R. I. 3086, Mar. 1931, 2 pp., 1 fig. on supp. plate; see also *Instruments*, vol. 4, no. 5, May 1931, pp. 277-278, 1 fig. Research work in Bureau of Mines cryogenic laboratory requires use of high-sensitivity galvanometers of d'Arsonval type in building that is subject to unusually severe vibrations; modified form of galvanometer suspension described by Julius in Annalen Physikalische Chemie of 1895, has damped vibrations successfully.

Generators

D-C. DESIGN. Relation of Coil and Brush Current in a Direct-Current Machine, R. M. Baker. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 383-386, 3 figs. General expression for current and voltage relations in armature coil; magnitude of circulating current in brushes; effect of over-compensation.

WATERWHEEL. A Comparison of Exciters for Waterwheel Generators, T. J. Woth. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 343-344, 3 figs. There are three principal types of exciters for waterwheel generators; direct-connected, separate turbine driven, and motor-generator set; advantages and disadvantages of each have important bearing on design and cost of complete station.

Heating

HEAT STORAGE. Solid-Core Thermal-Storage Heating Units, L. G. A. Sims and K. R. Sturley. *Engineering*, vol. 131, nos. 3407 and 3410, May 1, 1931, pp. 561-564, and May 22, pp. 664-665, 23 figs. Systems heretofore employed in Great Britain are not convenient in cases where single small rooms and single offices have to be heated; for this purpose, unit type of heater is needed, having loading of few kilowatts only, capable of being installed without alteration to structure of building; results of experiments made in Electrical Engineering Department of University of Birmingham on one of best Continental heaters, and development of greatly improved design.

Hoover Dam

Hoover Dam Will Provide 1,000,000 Hp. *Power Plant Eng.*, vol. 35, no. 12, June 15, 1931, pp. 643-645, 2 figs. Great project of Bureau of Reclamation includes dam 730 ft. high at Black Canyon on Colorado River, power plant, diversion and water control works and other features; general plan and section of Hoover dam, showing cofferdams and diversion tunnels.

Hydroelectric

POWER DEVELOPMENTS. A Power Development on the Columbia River, T. B. Parker. *Stone and Webster Jl.*, vol. 48, no. 5, May 1931, pp. 331-345, 7 figs. Rock Island hydroelectric development on Columbia River 12 mi. downstream from City of Wenatchee, Washington is built for Puget Sound Power and Light Co.; development will have several novel features, and will be first large low head development in Northwest it will be designed for ultimate capacity of 150,000 kw. under normal head of 48 ft.; initial installation will be 60,000 kw.

Power Plants

PUMPED STORAGE. Pumped Storage for Regeneration, L. F. Harza. *Power Plant Eng.*, vol. 35, no. 2, June 1, 1931, pp. 597-601, 4 figs. Methods of storing energy on large commercial scale; European practise of pumped storage power; pump-fed storage plants in Germany; design and operation features of several large plants in Germany; list of advantages and disadvantages of hydraulic storage; efficiency of conversion; economical capital expenditure limit.

REMOTE CONTROL. Automatic and Remotely Controlled Hydro-Power Plant. *AEG Progress*, vol. 7, no. 5-6, May-June 1931, pp. 99-106, 8 figs. Review of automatic and remotely controlled plant on basis of experience accumulated by AEG is construction of numerous automatic hydro-power stations for output totalling well over 100,000 kw.; important factors requiring study when planning electrical section of small and medium sized stations.

Insulating Materials

RUBBER. Rubber for Electrical Uses, A. R. Dunton and A. W. Muir. *Elecn.*, vol. 106, no. 2762, May 8, 1931, pp. 679-681, 1 fig. Vulcanization; tapes, flexible wire and cable insulation; ebonite and vulcanite; molding difficulties.

SPECIFICATIONS. Report of Committee D-9 on Electrical Insulating Materials. *Am. Soc. Testing Mills—Advance Paper*, no. 74, for mtg. June 22-26, 1931, 25 pp., 3 figs. Recommendations affecting standards and tentative standards; subcommittee I on insulating varnishes; subcommittee II on molded insulating materials; subcommittee on sheet insulation; subcommittee IV on liquid insulation; subcommittee VII on electrical tests; section A, of subcommittee IV, on neutralization methods for electrical insulating oils; electrometric methods for determination of neutralization number of mineral insulating oils.

Lamps

INCANDESCENT. Report of the Lamp Committee—June, 1931. *Nat. Elec. Light Assn.—Pub.*, no. 136, June 1931, 8 pp., 10 figs. Statistical data, covering incandescent-lamp industry; lamp developments that have taken place during year; importance of applying proper voltage lamp to obtain most economical and best results.

TUNGSTEN. Production of Color from Tungsten Lamps, M. Luckiesh. *Elec. World*, vol. 97, no. 14, Apr. 4, 1931, p. 645. Amount of light emitted in each of spectral regions by various sizes of tungsten lamps is listed.

Lighting

The Art of Illumination—II, J. W. T. Walsh. *Illum. Engr.*, vol. 24, May 1931, pp. 111-114. Specimen installations in many different classes of lighting problems ordinarily met with in practise.

AUTOMATIC CONTROL. The Automatic Control of Lighting Installations, E. H. Vedder and S. G. Hibben. *Illum. Eng. Soc.—Trans.*, vol. 26, no. 5, May 1931, pp. 517-523 and (discussion) 523-525, 8 figs. on supp. plates. Changing customs and requirements that impose more difficult demands upon manual control of many lighting circuits, have brought about logical development of automatic light-sensitive switching devices; photoelectric tube constitutes foundation of automatic control units, which, with its accessories and typical assembly, is described briefly; several actual and some suggested applications are mentioned, that seem destined to widen service to which artificial light will soon be put.

BUILDINGS. Electric Light on Metal in Architecture, E. Clute. *Elec. Specifications*, vol. 3, no. 5, May 1931, pp. 14-22, 11 figs. First of series of articles on materials in combination with electricity; examples showing effects of amber light on nickel grill and aluminum leaf of recessed light source, walls of black marble of light on nickel-chrome steel of reflector casings, crestings of store fronts and doors, red marble walls with buff veining on corrugated white metal backing of recess, grille of carved satinwood painted in polychrome; lighting and floodlighting features of various outstanding buildings of recent date are illustrated.

Lightning Arresters

TESTING. Cathode-Ray Oscillograph Tests Arrester Production, O. A. Ackermann. *Elec. World*, vol. 97, no. 19, May 9, 1931, p. 866, 2 figs. Criterion for acceptability of unit blocks which make up autovalve lightning arrester is volt-ampere curve; Westinghouse Electric & Manufacturing Company is using cathode-ray oscillograph in connection with surge generator for purpose of testing; oscillograph used for this purpose is of glass tube type, developed in Westinghouse Company originally for television purposes.

Lightning Protection

HIGH TENSION LINES. 220-Kv. Arrester on Long Line, G. C. Dill. *Elec. World*, vol. 97, no. 18, May 2, 1931, pp. 804-806, 6 figs. Hydro-electric power commission of Ontario recently has placed on 220-kv. side of Leaside substation near Toronto unique and notable installation of four 3-phase SV autovalve lightning arresters; protection problem was difficult; it would require 22 units to handle these dynamic over-voltage conditions of 266 kv. line to ground; arresters that were decided upon meet these two requirements by new and very unique design.

Loud Speakers

A Loud Speaker Good to Twelve Thousand Cycles, L. G. Bostwick. *Bell Laboratories Rec.*, vol. 9, no. 9, May 1931, pp. 433-436, 5 figs. In loud speaker under discussion, factors that usually cause high frequencies to be suppressed have been taken into consideration; diaphragm is made of .002-in. duralumin and is little over one inch in diameter; moving coil of aluminum ribbon wound edgewise is attached to diaphragm at periphery of embossed section and vibrates in very strong magnetic field in usual way; diaphragm and moving coil weigh together but 160 mg.

MOVING COIL. The Moving Coil Loud Speaker, H. M. Clarke. *Experimental Wireless*, vol. 8, no. 93, June 1931, pp. 304-306, 2 figs. If no allowance is made for possible change in electrical constants, dynamic impedance attributed to moving system and measured by difference of input resistance and reactance of system when in motion, from those of system at rest, may be considerably in error; with view to observing possible existence of such changes, author has carried out experiments.

Magnetic Hardening

METALS. Hardening Metals by Rotating Magnetic Fields, E. G. Herbert. *Metallurgia*, vol. 3, no. 18, Apr. 1931, pp. 219-221, 8 figs. Author describes his discovery of remarkable changes produced in metals by action of rotating magnetic field; hardening of alloy steels; application to non-ferrous metals, such as duralumin, rod brass and brass sheet.

Hardening Metals by Rotating Magnetic Fields, E. G. Herbert. *Metallurgia*, vol. 4, no. 19, May 1931, pp. 9-13, 17 figs. New developed magnetic phenomena is applicable to hardening of tools of any type or design; treatment occupies not more than two minutes at temperatures not exceeding 200 deg. cent.; data on experiment with alloy steels, duralumin and brass; graphs indicating results and comparison with other hardening processes. Bibliography.

Magnetic Testing

IRON AND STEEL. Relation Between Magnetic Properties, Impact Strength and Hardness, H. Styri. *Am. Soc. Testing Matls.—Advance Paper*, no. 33, for mtg. June 22-26, 1931, 12 pp., 4 figs. Results of investigation of subcommittee of Society's Committee A-8 on magnetic analysis, formed to investigate relationship between magnetic testing and impact strength and hardness; results are summarized in graphical form.

Magnets

DESIGN. Permanent Magnets for Electronic Instruments, W. H. Hoppe. *Electronics*, vol. 2, no. 5, May 1931, pp. 636-638, 3 figs. Permanent magnets represent inconspicuous but important part of many electronic devices, *e. g.*, measuring instruments, sound pickups and other well-known apparatus; principles of design of such magnets are described.

Measurements

Accurate Measurement of Small Electric Charges by a Null Method, L. S. Taylor. *U. S. Bur. Standards—Jl. Research*, vol. 6, no. 5, May 1931, pp. 807-818, 5 figs. partly on supp. plate. New method for calibrating null system in such manner that capacity of leads does not enter and which, therefore, permits reduction in calibration error to one-tenth; when system is once calibrated in manner described, any unknown capacity whatever may be added to leads without affecting measurement of desired quantities; applications to measurements of current, charge and capacity.

Measuring Instruments

Electrical Maintenance Instruments, A. I. Greenwood. *Power Plant Eng.*, vol. 35, no. 12, June 15, 1931, pp. 669-670, 4 figs. Grounds and insulation tests with discussion of methods and instruments used in making them; accurate resistance measurement.

Metering

THREE-PHASE. The Metering of Three-Phase Supplies, O. Howarth. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 413, May 1931, pp. 637-646, 3 figs. Discussion by A. E. Moore, A. E. Jepson, A. M. Strickland and others, of paper previously indexed from issue of Mar. 1931; also reply by author.

Meters

Meter Committee Reports. *Elec. West.*, vol. 66, no. 6, May 15, 1931, pp. 385-401, 25 figs. Reports of Pacific Coast Electric Association on meter obsolescence; reactive kva. metering; special tests and investigations; determining ground resistance; calibration of high voltage potential transformers using standard of different voltage rating; oscillographic measurement of time intervals; tests on various forms of relays; operating problems of meter department.

Motors

CAPACITOR. The Design of Capacitor Motors for Best Starting Performance, B. F. Bailey. *Univ. Mich.—Dept. Eng. Research—Eng. Research Bul.*, no. 19, Apr. 1931, 23 pp., 12 figs. Having been called upon to design large number of capacitor motors, writer has endeavored to simplify fundamental theory and methods of making necessary computations; portion of theory which relates to locked or starting torque of capacitor motors is presented in its simplified form.

SQUIRREL CAGE. Full-Voltage Starting Simplifies A-C. Motor Applications, E. W. Henderson. *Power*, vol. 73, no. 20, May 19, 1931, pp. 770-772, 7 figs. Squirrel-cage motors have been developed that can be started by connecting them directly to line and yet maintain inrush current within N.E.L.A. recommendations; these motors have full-speed characteristics practically as good as those started on reduced voltage, and employ much simpler and less expensive starting equipment.

THREE-PHASE. Three-Phase Commutator Motors for Outputs Up to 16-5 kw., M. Mogensen. *Brown Boveri Rev.*, vol. 18, no. 6, June 1931, pp. 187-195, 22 figs. For many years Brown, Boveri & Co., have made complete range of three-phase commutator motors intended for textile industry for variable speed individual drive of ring spinning and twisting frames; they have also found many other fields of application; range of motors has undergone repeated improvements; new series of three-phase commutator motors thus formed is described in greater detail.

Networks

CURRENT CONVERSION. Planning Successive Steps in Network Cut-over, C. W. Evans. *Elec. World*, vol. 97, no. 20, May 16, 1931, p. 909, 1 fig. 13-kv. feeders formed nucleus from which small sections were gradually enlarged until two or three sections could meet and merge into one; this gradual expanding of smaller section was greatly simplified by secondary junction boxes, which were already installed in most manholes; since these boxes are provided with links it was simple matter to sectionalize new system from old.

DESIGN. A Non-Mathematical Analysis of the Measurement of Symmetrical Components, A. P. Hayward. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 351-357, 17 figs. Simple, non-mathematical analysis of physical basis of measurement. Bibliography.

OVERVOLTAGES. Over-Voltage Problems, A. H. Von Altmann. *Engineer*, vol. 151, no. 3934, June 5, 1931, pp. 634-635, 5 figs. Attempt is made to show that most dangerous over-voltages are caused by direct lightning strokes; proposals submitted in recent years for protecting overhead lines and plant; apparatus used for combating overvoltage phenomena.

UNDERGROUND. Underground Systems Reference Book. National Electric Light Association. N. Y., The Association, 1931, 377 pp., illus., diagrs., charts, tables, $4.00. Number of leading American authorities have assisted in editing this description of accepted practise in design, construction and operation of underground systems of electric distribution; cables and their insulation, conduit and manhole design and construction, cable installation, splices and terminals, cable operation, miscellaneous equipment and safety practises are discussed in detail. Bibliography of over 4,000 references. Eng. Soc. Lib., N. Y.

Ohmmeters

VACUUM TUBE. A Thermionic Megger with Linear Scale, O. Stuhlman. *Franklin Inst.—Jl.*, vol. 211, no. 5, May 1931, pp. 617-625, 5 figs. Writer proposes to use any tube with dynatron characteristics; if change in slope of given phase of characteristic can be shown to change in proportion to change in external resistance it should follow that for predetermined current, voltmeter recording potential across filament and plate can then be calibrated to read resistances directly; voltmeter's linear scale is then direct reading megohmmeter.

Photoelectric Cells

Concerning the Grid-Leak of a Grid-Photoelectric Tube, T. Asada and K. Hagita. *Inst. Elec. Engrs., Japan—Jl.*, vol. 51, no. 2, Feb. 1931, pp. 99-102, 5 figs. In previous paper on "Supersensitive Photoelectric Tube," it is reported that so-called grid-photoelectric tube or grid-tube is much more sensitive than other ordinary photoelectric tubes, and it has no phenomena of time-lag and fatigue; in this paper it is reported that this connection of grid with filament through a high resistance, which is similar to grid-leak of a triode, is very important for grid-tube. (In Japanese with English abstract on pp. 17-19.)

INDUSTRIAL APPLICATIONS. Power Control by Means of Phototubes, W. R. G. Baker, A. S. Fitzgerald and C. F. Whitney. *Electronics*, vol. 2, no. 5, May 1931, pp. 632-633, 6 figs. Use of phototube in various fields; wiring diagrams of light-operated relay circuit, system controlling power by light beams, Selenium-Thyratron system for illuminating control and smoke-density recorder circuit; color comparator by which phototube matches roast of coffee.

Power Factor

IMPROVEMENT. Alignment Charts for Power Factor Improvement, W. A. Barclay. *Elec. Engr. Australia and New Zealand*, vol. 8, no. 1, Apr. 15, 1931, pp. 19-22, 3 figs. Use of two charts, which author has drawn up, in determining size of condenser required for correcting power factor of circuit by specified amount; charts bring calculation of corrective kva. to simplest possible terms.

Power-Factor Correction Cuts Costs, J. F. Wulfetange, Jr. *Elec. World*, vol. 97, no. 14, Apr. 1931, pp. 628-631, 3 figs. Industrial plants in Pittsburgh, Pa., are encouraged to correct power factor by new "W" rate of Duquesne Light Co., offering low energy rates for high power factor demands; capacitors have proved economical, effective means of raising kw./kva. ratio either in supplementing or in substitution for synchronous machines.

Protection

HIGH TENSION LINES. The Petersen Coil for Power System Arc Suppression, W. F. Mainguy. *Elec. News*, vol. 40, no. 10, May 15, 1931, pp. 47-49 and 58, 3 figs. Short review of European development; notes on principle of coil which is applicable only to ungrounded system; solidly grounded neutral system; isolated neutral system; size of coil; connection of coil.

Radio

AMPLIFIERS—COUPLING. Theory and Operation of Tuned Radio-Frequency Coupling Systems, H. A. Wheeler and W. A. MacDonald. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 5, May 1931, pp. 738-803 and (discussion) pp. 804-805. Gain of amplifier can be held uniform or made to vary with frequency in any desired manner consistent with amplifying ability of tube and tuned secondary circuit, and without appreciable loss of selectivity; large variety of these improved coupling circuits is shown and classified in terms of fixed and varying components of equivalent mutual inductance; number of these coupling systems from commercial receivers are described in terms of coil structure, electrical constants, and performance.

BROADCASTING. Radio Network Broadcasting, R. H. Owen and W. G. Rubel. *Engrs. Bul.*, vol. 15, no. 4, Apr. 1931, pp. 5, 28-29 and 35, 2 figs. Discussion is intended to give more or less comprehensive idea of what is involved in connection with network broadcasting; present day program transmission circuits in United States are on "voice frequency basis"; in transmitting programs over wire network, it is important that volume range be held within proper limits; it is one of obligations of one who handles program pick-up to hold his range of volume between proper limits.

BROADCASTING, LONG WAVE. Low-Frequency High Power Broadcasting as Applied to National Coverage in the United States, W. H. Wenstrom. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 6, June 1931, pp. 971-983, 3 figs. With P. P. Eckersley's general theory derived from north European practise as starting point, possibilities of broadcasting in United States on frequencies around 200 kc. are examined from viewpoint of national coverage; it is shown that under specified conditions Eckersley's curves can be applied approximately to American terrain.

DIRECTION FINDING. The Practical Correction of a Wireless Direction-finder for Deviations due to the Metalwork of a Ship, C. E. Horton. *Experimental Wireless*, vol. 8, no. 91, Apr. 1931, pp. 195-198, 11 figs. Brief review of errors that may occur was due to immediate surroundings of direction-finder as in a ship. Before Inst. Elec. Engrs.

TELEPHONE, SHORT WAVE. Single Side Band Short-Wave Wireless Telephony. *Engineer*, vol. 51, no. 3932, May 22, 1931, pp. 570-571, 4 figs. New system of radio telephony in which single side band is applied to short-wave transmission, was demonstrated at experimental radio station of Matérial Téléphonique at Trappes, near Paris; results represent reward of long search for means of applying single side-band method, with its well-known advantages, to short-wave radio transmission, problem that has hitherto presented almost insurmountable difficulties.

ULTRA-SHORT WAVE. Communication on the quasi-optical frequencies, E. Karplus. *Electronics*, vol. 2, no. 6, June 1931, pp. 666-667, 4 figs. Problems in communication waves in Barkhausen and Kurz range; various laboratory equipment; transmitter and receiver by I. T. & T. experiments across English Channel on wavelength of 18 cm.; notes on problems of reception; ultra-high frequency wavemeters.

Railroads

AUTOMATIC CONTROL. Automatic Operation at the Cleveland Union Terminals, F. E. Jaquay. *Gen. Elec. Rev.*, vol. 34, no. 6, June 1931, pp. 350-356, 9 figs. Automatic and supervisory control which has now been in successful operation for nearly a year on Cleveland Union Terminal Electrification is very important part of this project which, at time of placing in service, was first application of 3,000 volts d-c. for heavy electric traction in east; electrified zone includes total of approximately 17 mi. of route and some 60 mi. of single track; importance of 100 per cent reliability in operation of this system handling between 100 and 150 trains daily is stressed.

REGENERATIVE CONTROL. Railway Regenerative Braking, J. A. Colaco. *Elec. Rev.*, vol. 108, no 2793, June 5, 1931, pp. 945-946, 4 figs. General improvement in operating conditions, more than saving in energy consumption, has justified adoption of system on Great Indian Peninsula railway.

SIGNALS AND SIGNALING. The Effect of Signalling on Track Capacity, C. R. Byrom. *Inst. Transport—Jl.*, vol. 12, no. 7, May 1931, pp. 326-340 and (discussion) 340-347, 8 figs. Historical review of signal developments; automatic signals; route indicators; manual versus automatic signaling.

SIGNALS AND SIGNALING, AUTOMATIC. N. Y. C. Re-Signals Tracks Entering Grand Central Terminal. *Ry. Age*, vol. 90, no. 18, May 2, 1931, pp. 856-858, 3 figs. Train operation in either direction on each of four tracks facilitates traffic and increases track capacity; track and signal plan of territory between Grand Central Terminal and Mott Haven; outline of new signaling system.

TRAIN CONTROL—CAB SIGNALING. Taking the Flicker Out of Cab Signal Lights. *Ry. Elec. Engr.*, vol. 22, no. 5, May 1931, pp. 119-121, 5 figs. Both track and locomotive irregularities may result in fluctuating indications; close attention to relay pick-up values and track circuit conditions will remedy trouble causes of fluctuating indications; typical 60-cycle loop system of continuous control, double track; typical coder continuous track circuits, track d-c. control and a-c. signal circuit.

UNITED STATES. 1930 a Difficult Year for the Electric Railways, E. J. Murphy. *Aera*, vol. 22, no. 5, May 1931, pp. 260-266. Sharp reduction in traffic and revenues produced by business depression severely taxed resources of industry in 1930; only by again stepping up operating efficiency and, in addition, closely adjusting service to reduced volume of business were they able to meet all obligations; tabular review of combined operations of electric railroad companies for 1929 and 1930.

Rate Making

POWER INDUSTRY. More Equitable Rate Forms an Industry Obligation, T. O. Kennedy. *Elec. World*, vol. 97, no. 22, May 30, 1931, p. 1008. With rate schedules based on rate per kw-hr. it is only natural that our customers should look upon electricity as commodity, whereas it can equitably be sold and charged for only as service; it is obligation of our commercial departments to promote adoption of more equitable type of rate.

Reactive Power

METERING. Reactive Kva. Metering—VIII, E. C. Goodale. *Elec. West.*, vol. 66, no. 5, May 1, 1931, pp. 233-234, 3 figs. Three-element meters give accurate registration of reactive Kva. on four-wire circuits if voltages are balanced.

Rectifiers

MERCURY-ARC. Mercury-Arc Power Rectifiers—Their Construction and Operation, W. E. Gutzwiller. *Power*, vol. 73, no. 24, June 16, 1931, pp. 950-953, 7 figs. Mercury-arc power rectifiers have in few years been developed to where they are now keen competitor of rotary converters and motor-generator sets; built in siz up to 6,000 kw., for voltages up to 3,000 and to supply all kinds of d-c. loads; cross-section through large mercury-arc power rectifier; diagram of connections for 6-phase manually operated rectifier unit.

Mercury Arc Rectifier for Electric Railroads, L. G. Raschkovsky. *Electriichestvo*, no. 9, May 1931, pp. 466-469, 5 figs. Characteristic properties; advantages over synchronous con verters; application on electric locomotives.

3,000-Volt Traction Rectifiers. *Engineer*, vol. 151, no. 3933, May 29, 1931, pp. 606-607, 2 figs. In electrification program by Delaware, Lackawanna and Western Railway, for converting 60-cycle a-c. into 3,000-volt d-c., mercury-arc rectifiers were chosen, in preference to motor-generators, because of their relatively low first cost, high efficiency, and ability to carry heavy overloads without injury; other advantages are small floor space and simple foundations. From article, by E. L. Moreland, previously indexed from Gen. Elec. Rev., Mar. 1931, under classification of Railroad Electrification—United States.

Relays

HIGH TENSION LINES. Theory and Application of Relay Systems—Ground-Fault Protection of Loop Systems—I, P. H. Robinson and I. T. Monseth. *Elec., Jl.*, vol. 28, no. 6, June 1931, pp. 375-378, 5 figs. For simple loop system consisting of one generating station and having transformer neutrals grounded at only this one point, impedance or directional-overcurrent ground relays are most frequently applied; more complicated systems require use of other types of relays; loop system with one grounded neutral point discussed.

TESTING. Some New Information Regarding the Installation and Testing of Brown Boveri Distance Relays, J. Stoecklin. *Brown Boveri Rev.*, vol. 18, no. 5, May 1931, pp. 175-179, 7 figs. Brown Boveri distance relay protection has been adopted to great extent in short time, and valuable suggestions have more than once been made by users with view to simplifying installation of relays, and also to render possible carrying out of periodical tests.

Remote Metering

The Midworth Distant Repeater. *Elec. Engr. Australia and New Zealand*, vol. 8, no. 1, Apr. 15, 1931, pp. 22-24, 4 figs. Instrument for providing remote indication of various values, and of its application for measuring bulk electricity supplied to Melbourne city council.

Substations

Laconia Avenue Distribution Station of the Bronx Gas and Electric Company, S. Wilder. *Gen. Elec. Rev.*, vol. 34, no. 6, June 1931, pp. 374-376, 5 figs. Purpose of article is not to present details of design or operation of automatic supervisory equipment but rather to describe briefly typical substation, furnished with such equipment, and to give some operating data in regard to installation; electrical energy purchased from United Electric Light and Power Co. is supplied over 13,200-volt feeders from this company's Sherman Creek and Hell Gate stations.

Switchboards

MINIATURE. Miniature Switchboards: A New Type of Control Switchboard for Electric Power Stations and Substations, P. Sporn. *Gen. Elec. Rev.*, vol. 34, no. 6, June 1931, pp. 336-342, 10 figs. Purpose and development of miniature switchboard; description of board and equipment; installations; advantages; experience in service.

Switchgear

Substation Switchgear, F. C. Orchard. *Elec. Times*, vol. 79, no. 2066, May 28, 1931, pp. 963-964, 3 figs. Main principles underlying design of substation are that apparatus shall be of sound design and construction so that breakdown is infrequent and apparatus shall be arranged so that it can operate under conditions for which it is designed; design of switchgear, which is most important apparatus in substation, is very largely effected by characteristics of high voltage system and not entirely by service to be given by substation.

AUTOMATIC. Automatic Switching Equipment in Industry, F. P. Brightman. *Gen. Elec. Rev.*, vol. 34, no. 5, May 1931, pp. 284-287, 4 figs. Applications in mines, steel mills, paper mills, and glass industry preferred-emergency service; advantages derived from use of automatic equipment are elimination of full time operator, of difficulties attributable to inefficient manual operation; reduction in feeder losses; reduction in number and duration of outage.

METAL CLAD. Metal Clad Switchgear. *Elec. West*, vol. 66, no. 6, May 15, 1931, pp. 334-339, 9 figs. "Report on types used and typical installations by Electrical Apparatus Committee of Pacific Coast Electric Association.

Telephone

Recent Development in Telephony, E. H. Colpitts. *Military Engr.*, vol. 23, no. 129, May-June 1931, pp. 247-254, 9 figs. Growth and improvements in toll circuits; toll cable improvements; gas pressure testing of cable; open-wire circuits and voice-frequency use; open-wire carrier circuits; program translation; Cuba-Key West cables; radio telephone; improvements in wire insulation; private branch exchange telephone system; new order receiving equipment.

CARRIER CURRENT. Current Carrier Telephony, A. C. Timmis. *Instn. Post Office Elec. Engrs.—Paper*, no. 131, for mtg. Feb. 11, 1930, 47 pp., 23 figs. Carrier telephony over transmission lines with particular reference to lines used primarily for ordinary telephone circuits; general principles; transmission; present state of art in various countries; future development.

INDUCTIVE INTERFERENCE. Foreign Systems Co-ordination Committee Reports. *Elec. West*, vol. 6, May 15, 1931, pp. 342-360, 23 figs. Report of Pacific Coast Electric Association on inductive coordination of Hoover Dam transmission line; Serjdetour telephone protector; power company telephone line protection; tests on soldered sleeve joints in telephone line construction; sleeve rolling tool and single tube sleeve; remote alarms over telephone circuits; radio coordination; common neutral.

Inductive Coordination Laboratory, E. L. Fisher. *Bell Laboratories Rec.*, vol. 9, no. 10, June 1931, pp. 481-485, 7 figs. To study under fully controlled conditions some of various effects of voltages induced in telephone lines by disturbances in neighboring power circuits, assembly of equipment has been made in laboratories.

LONG DISTANCE—TOLL SYSTEM. Standard Switching Plan for Telephone Toll Service, H. S. Osborne. *Commercial Standards Monthly*, vol. 7, no. 11, May 1931, pp. 351-352. Efficiency increased through improved coordination in planning, designing, and arrangement of toll plant; general plant described as comprehensive countrywide network of toll circuit facilities connecting important switching offices over which practically all traffic, not handled by direct circuits, will be routed.

Teletypes

The Engineering and Traffic Aspects of Teleprinter Development, A. P. Ogilvie and F. W. Dopson. *Telegraph and Telephone Jl.*, vol. 17, no. 194, May 1931, pp. 176-178, 7 figs. Type of apparatus that is being installed and general effect of its adoption on telegraph service as whole. Before Telephone and Telegraph Soc., Lond.

Testing

HIGH TENSION LINES. Fault Currents on 110-kv. Line Checked by Service Tests, L. M. Robertson. *Elec. West*, vol. 66, no. 5, May 1, 1931, p. 235, 2 figs. Measuring false currents, potential gradients, and telephone interference on its new 110-kv. wood-pole, H-frame transmission line of Public Service Co. of Colorado, are described; two types of structures were tested, one, with all insular and crossarm hardware bonded and grounded and connected to overhead wire, other type made full use of wood for insulation.

Transients

HIGH TENSION LINES. Automatic Recording of System Disturbances, J. T. Johnson, Jr. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 335-339, 12 figs. With Osiso, records of transients on system of Alabama Power C . have been recorded automatically which showed clearly and sharply all but first cycle; Osiso was mounted on portable wooden base containing all accessories necessary for automatic operation and then used for taking hundreds of records in score of different studies.

Transmission Lines

DESIGN. Transmission Line Built Across 53 Others, F. Curtis, *Elec. West*, vol. 66, no. 7, June 1, 1931, pp. 616-617, 5 figs. Design of 62-mi. 110-kv. interconnection over 53 power lines, some of 66-kv. potential, 44 telephone lines, two trolley lines, 17 railroads, two state highways, 50-ft. water tower and seven houses between San Bernardino substation of Southern Sierras Power Co. and Los Angeles Gas and Elec. Corp., Seal Beach steam electric plant.

Welding

ARC. Research Covering Alternating Current Arc Welding, G. A. Hughes and R. C. McBridge. *Iron and Steel Engr.*, vol. 8, no. 6, June 1931, pp. 241-246, 12 figs. Possibilities of a-c. arc welding, *i. e.*: chemical analysis of metal deposited, rate of deposit, ductility, tensile strength, penetration, non-ferrous metal, electrical characteristics, and bare and coated electrodes, are investigated; test results are given.

Study of Variables the Basis of Progress in Fusion Welding, C. A. Adams. *Power*, vol. 73, no. 21, May 26, 1931, pp. 813-814, 1 fig. Research has disclosed importance of understanding effects of metallurgical, chemical, mechanical and electrical variables on art of fusion welding, and has made possible its application to power plant equipment.

CAST IRON. Cast Iron To-day, A. B. Everest. *Welding Jl.*, vol. 28, nos. 330 and 331, Mar. 1931, pp. 80-83 and Apr., pp. 102-106 and (discussion) 106-109, 15 figs. Paper is presented in belief that welding engineers to-day are becoming increasingly interested in application of their art to all engineering structures, among them castings, and therefore are interested in structure and nature of commonest metal used for cast structures. Before Instn. Welding Engrs.

ELECTRODES. A New Improved Electrode for Arc Welding Stainless Steel. *Welding Jl.*, vol. 28, no. 331, Apr. 1931, pp. 118 and 120, 5 figs. New, improved electrode for arc welding of stainless steel has been recently developed by Lincoln Research Laboratories and is now being manufactured by Lincoln Electric Co., Cleveland, Ohio.

IRON AND STEEL PLANTS. Maintenance Welding in Steel Plant is Essential, E. L. Quinn. *Welding*, vol. 2, no. 5, May 1931, pp. 320-324 and 331. Application of thermit, electric arc and oxyacetylene welding to various types of repair work; procedure in welding of steel, cast iron, bronze welding of cast iron; surface hardening alloys; qualification of operators.

PIPE LINES. Progress in Arc Welded Construction of Oil Pipe Lines, J. F. Lincoln. *Oil Weekly*, vol. 61, no. 8, May 8, 1931, pp. 67-68, 72 and 76, 10 figs. Review of development in 1930; physical properties of welded joints; resistance to corrosion; ductility; welding procedure; tacking; rolling welds; tie-in welds; speed of welding; equipment; oil-carrying pip lines welded by new shielded arc process; 1010 mi. of pipe line containing 106,885 joints fabricated or now under construction.

PRESSURE VESSELS. Electric Welding Applications to Steam Pressure Vessels. *Power Plant Eng.*, vol. 35, no. 12, June 15, 1931, pp. 667, 4 figs. Electric welding of steam piping and directly fired steam drums has now passed experimental stage of development and during past year and half number of noteworthy applications have been made in power plant field; review of outstanding applications.

UNITED STATES. Some Achievements in Arc Welding in the United States During 1930, L. D. Meeker. *Sheet Metal Industries*, vol. 5, no. 1, May 1931, pp. 49-50. Welded steel structures built in 1930; automatic welding machines; atomic-hydrogen welding.

Welds

TESTING. Testing Butt Welds by Magnetic Methods, T. R. Watts. *Elec. Jl.*, vol. 28, no. 6, June 1931, pp. 389-391, 6 figs. In magnetic testing of butt welds in steel, faults are detected because of their higher reluctanc ; means of detecting regions of abnormally high reluctance, that is, faults, may be classified as "magnetrographic inspection" and measurements of leakage flux by means of weld-test meters.

Industrial Notes

American Insulators for Egypt.—The Ohio Brass Company, of Mansfield, Ohio has received a third order for insulators and transmission line hardware to be used in connection with the extensive electrification projects of the Egyptian government, now nearing completion in the Nile Valley. This most recent order for suspension insulators and hardware fittings amounts to approximately $79,000 and brings the total volume of orders received during the past twelve months for this project to $250,000.

General Electric Reports Decreased Sales.—Orders received by the General Electric Company for the first six months of 1931 amounted to $141,428,978, compared with $190,313,758 for the corresponding period last year, Gerard Swope, president, announced today. Sales billed for the six months of 1931 amounted to $141,180,091.13, compared with $197,229,346.82 for the corresponding period last year.

The National Electric Products Corporation, Pittsburgh, announces the opening of its own branch at 400 Potrero Street, San Francisco, taking over the stocks and active operations for the company on the Pacific Coast. Garnett Young & Company, who have for many years represented the National Company, resigned April 8 to take effect July 15.

The Square D Company of Texas, a subsidiary of the Square D Company, Detroit, recently opened its new factory at 3111 Polk Avenue, Houston, to service the southwest's electric equipment requirements. The Square D Company of Texas was organized in 1928 to serve the southwest with special switchboards, lighting and power panelboards, special motor control and standard Diamond E material. Branches are operated in Little Rock, Ark., Dallas and Houston, Texas.

A New Safety Switch.—The Rowan Controller Company, Baltimore, manufacturer of completely oil immersed control equipment, has recently introduced a combination safety switch and magnetic contactor for use with small alternating-current motors. The equipment can be furnished up to and including 5 horsepower, 220, 440 or 550 volts. The unit is compactly built so that it occupies a minimum of wall space, and the fact that it is completely oil-immersed makes it vapor-proof, weather-proof, and dust-tight.

New Motor Starter.—The Electric Controller & Manufacturing Company, Cleveland, Ohio, announces a new line of explosion-proof motor starters, type ZS, across-the-line, providing for full voltage starting of squirrel cage motors. These starters may also be used with an automatic field switching panel for synchronous motors and for the control of the primary of slip-ring motors. An oil tank which contains the main line contactor, is equipped with a sight oil gage to indicate the oil level inside the tank. Bolted to the rear of the tank is an explosion-proof case which contains the overload relay panel and which also serves as a conduit connection box. Maintenance is greatly reduced, because the operating mechanism is always well protected against moisture and corrosion.

Recent Westinghouse Orders.—The Westinghouse Electric & Manufacturing Company announces recent orders that include a 25-kva. synchronous condenser and automatic control switching equipment for the Puget Sound Power & Light Company. An order from the Management & Engineering Corporation, of Chicago, covers eight 2,500-kva. and seven 1,667-kva. transformers to be used to increase the capacity of the Indianapolis Power & Light Company 33,000-volt load. The Commonwealth Edison Company has ordered the first alternating-current calculating board for commercial use at a cost of approximately $50,000. The board will be located at Chicago and will be used to determine system operating conditions under various loads and schemes of operation. Only two other alternating-current calculating boards are in use,— one is at the Westinghouse plant in East Pittsburgh and the other at the Massachusetts Institute of Technology, Cambridge, Mass.

Burgess Radiovisor Bridge.—The Radiovisor Division of the Burgess Battery Company, 295 Madison Ave., New York, has announced a new light-sensitive cell representing the original development of British scientists, followed by the ingenious applications by German technicians, and finally the adaptation of the cell and its circuit to American practise. The new cell or bridge consists of a tall glass tube with a three-pronged base similar in general appearance to an ordinary radio tube. Inside the bulb and supported by two heavy lead-in wires is a plate of glass on the front side of which are two interlocking comb-like electrodes of gold leaf fused in place. Covering these electrodes is a thin layer of light-sensitive enamel derived from selenium. Extreme ruggedness is claimed for the new light-sensitive device, including the capability of handling relatively heavy current. Each bridge has maximum rating of 0.15 watt for 1.5 sq. in. of sensitized surface. The bridge is rated as possessing a high ratio of dark resistance to resistance when subjected to an illumination of 10-ft. candles, and is practically independent of voltage.

Trade Literature

Transformers.—Bulletin 170, 64 pp. Describes Wagner power transformers. Wagner Electric Corporation, 6400 Plymouth Street, St. Louis.

Safety Switches.—Catalog 100-A. Describes Wadsworth safety switches and distribution panels. Wadsworth Electric & Manufacturing Company, Covington, Ky.

Transformers.—Bulletin 3006, 8 pp. Describes a new transformer for rural line service. Allis-Chalmers Manufacturing Company, Milwaukee.

Illumination. — Bulletin "Outdoor Sports Lighting," 16 pp. Includes specifications and photographs of typical installations. General Electric Company, Nela Park, Cleveland.

Motors.—Bulletin 520, 20 pp. Describes Ideal synchronous motors, 1 to 3,000 horsepower. Illustrations, application data and dimension charts are given covering the Ideal flywheel type synchronous motor (patented) and six other standard types of synchronous motors. A rather unusual method of giving dimensions is used whereby the approximate dimensions of any of the various types of motors for any horsepower and speed rating may be obtained. The Ideal Electric & Manufacturing Company, Mansfield, O.

Resistors.—Bulletin 19, 2 pp. Describes "Ribflex" vitreous enameled resistors. These resistance units consist of a metal alloy resistance ribbon, reflexed, wound on edge on a ceramic tube and banded at each end with heavy duty terminals. The entire unit is then covered with a fired-on vitreous enamel. The advantages claimed for this type of construction over any other form of tube resistor include—greater area for heat dissipation due to flat reflexed form of resistor element, wound on edge; high wattage for continuous duty; higher wattage for intermittent duty; easily assembled in associated apparatus due to individual units being available in low values of resistance; rugged terminals fitted with screws and nuts permit mounting by the terminals; classified as bare resistor under NEMA and Underwriters' rules. Ward Leonard Electric Company, Mount Vernon, N. Y.

The Mokelumne Hydroelectric Project

California's latest hydroelectric development activities are centered in the Mokelumne River property of the Pacific Gas and Electric Company. This project involves the complete redevelopment of the river, from water surveys to power distribution, and will make available a billion kilowatt-hours annually, ten times the output of a 1902 development on the same stream.

By
E. A. CRELLIN
Fellow A. I. E. E.
Pacific Gas and Electric Company, San Francisco

NOT OFTEN does an addition of generating equipment to an operating system involve all of the features of a complete power system, from the study of water storage and usage, all the way through generation and transmission to the step-down substations. It is this aspect of the Mokelumne River development of the Pacific Gas and Electric Company (Calif.) which seems to make it of more than passing interest. Hydroelectric features are treated in this article; a companion article (see pp. 713-718) discusses the transmission and distribution problems.

The Mokelumne River is one of the pioneer power streams of California. Its source is in Alpine County approximately 20 mi. south of Lake Tahoe at El. 9,700 whence it flows in a general southwesterly direction for some 120 mi. to a point where its waters join the San Joaquin River on their way to the Pacific Ocean through San Francisco Bay. The lower 60 mi. of the river is quite flat, lying at an elevation of less than 200 ft. above sea level.

The discovery of gold and its accompanying need for water for mining operations brought about the first developments on the Mokelumne River in the fall of 1857. A company formed in that year, and its successors continued in the water supply business until the properties were acquired by the Standard Electric Company of California in the late nineties for the purpose of generating power for transmission to San Francisco, 110 mi. away. Electra power house and its associated 60-kv. transmission line were placed in service May 6, 1902, one of the pioneer hydroelectric and high-voltage transmission projects of the world. In 1907 the original installation of five 2,000-kw. units was increased by the addition of two 5,000-kw. generators; for the past 29 years the plant has been in continuous operation.

Water storage facilities on the upper reaches of the Mokelumne totaled approximately 25,000 acre-ft. divided among several small reservoirs at relatively high altitudes. This water released as needed to augment the natural flow of the river was diverted in the vicinity of the junction of Tiger Creek and the Mokelumne River into two canals (each approximately 20 mi. long and with a combined capacity of some 200 sec-ft.) for delivery into the forebays above Electra power house. The annual output of power from the system was approximately 100,000,000 kw-hr. The foregoing introductory remarks are intended to

Plan and profile of Mokelumne River Development of the Pacific Gas and Electric Company (Calif.)

disclose the conditions existing at the time studies for the development of additional power on the Mokelumne River were begun.

Water Supply Development

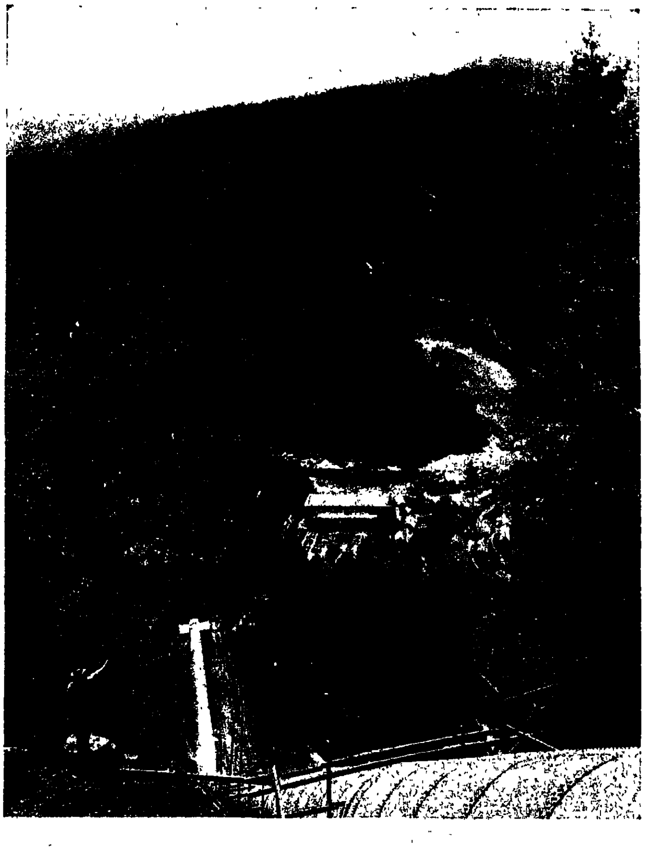
The upper portion of the Mokelumne River was relatively inaccessible and as a result, actual water record data for the upper portion of the water shed were not available. From 1906 to the present time, complete records of stream flow have been kept of readings taken at gaging stations located near the diversion into the conduits supplying water to Electra power house; and beginning with the early spring of 1924, additional gaging stations were installed at strategic locations on the upper river and certain tributary streams. The information obtained from these later stations was studied in connection with the long-time record of the original stations and runoff and storage possibilities were analyzed for 24 consecutive seasons. Runoff characteristics for the upper and lower portions of the river vary during the different months of the year. During the winter and early spring precipitation on most of the upper basin is in the form snow, while that on the lower portion of the development is rain. From the extensive water supply studies and accurate topographic maps it was possible to determine the most advantageous storage sites and to plan a comprehensive development for the most economical utilization of the water. A tabulation was prepared to show the probable use of storage water in maintaining a more or less uniformly regulated flow at the forebays of the various plants. Calculations of energy output showed that the average year would yield approximately 913,000,000 kw-hr., with 1,038,000,000 for a year of full supply and 489,000,000 for the dry-year period.

Consideration was given to the necessity of having peak output sufficient to meet system load conditions at all times, it being assumed that for dry years the peaks would be met by hydro power with steam power carrying the base load. Economic studies showed that the Mokelumne River development required back-up steam capacity of about 35 per cent of the peak, the hydro capacity representing 65 per cent of the peak. Likewise consideration was given to providing for the maximum release of stored water during the summer months (for the benefit of irrigation interests on the lower reaches of the river) which was consistent with maintaining peak demand throughout the late fall and winter. When the project is entirely completed it will involve a total water storage of some 200,000 acre-ft. and the generation of 1,000,000,000 kw-hr. annually, a tenfold increase over the original Electra development.

Two major storage reservoirs, the one on the Mokelumne River known as Salt Springs reservoir, the other on one of the principal upper tributaries and known as lower Bear River reservoir, will impound the runoff waters from their respective drainage areas. The regulation of flow in the Mokelumne River made possible by these two storage reservoirs together with the smaller reservoirs already in service, is the principal factor contributing to the increased power output. The spillway at Salt Springs dam is at El. 3,947; that of the Bear River dam at El. 5,816. The center-line elevation of the nozzles of the waterwheel units to be installed in the proposed rebuilding of Electra power house is at El. 685. Thus there is provided a total gross head of 3,262 ft. and 5,131 ft. respectively from the two main sources of storage, which head will be utilized in four steps by four power houses.

SALT SPRINGS DAM

The rock-fill dam chosen for the major Mokelumne development is believed to be one of the safest kinds of dam that can be built. (This type of dam has been very successful in California.) The canyon which is of solid granite made available at the dam site ample material for its construction. The inaccessible nature of the location necessitated the construction of approximately 50 mi. of roadway suitable for heavy trucking, and required the hauling of all materials involved over this entire distance by motor transport. The high cost of concrete materials at such a site made the estimated cost of a rock-fill dam approximately $2,000,000 less than would have been the case for a suitable concrete dam. Modern large-scale construction equipment was used on the job, including electrically operated shovels to load the rock cars and storage-battery locomotives to haul them.



Looking down the penstock toward Tiger Creek power house. The transmission line right-of-way may be discerned on the mountains opposite

Rock for the dam was obtained from quarries at different levels near the north abutment of the dam and from the spillway excavation on the south bank. The usual quarrying methods followed featured several "big shots," each of which required in excess of 50 tons of powder and brought down approximately 200,000 cu. yd. of granite.

The dam rises 328 ft. above the stream bed, has a crest length of 1,300 ft., is 900 ft. thick at the base, and contains approximately 3,000,000 cu. yd. of material. Approximately 225,000 cu. yd. of rock were derrick-placed to a uniform thickness of 15 ft. over the entire upstream face of the dam. This placed rock forms a foundation for an outer facing of reinforced concrete which covers the entire upstream slope, varying in thickness from 36 in. at the bottom to 12 in. at the top. Concrete was placed in continuously poured 60 x 60 ft. panels of heavily reinforced concrete, each completely isolated from its neighbors by expansion or contraction joints fitted with copper water seals. The horizontal joints were poured concrete-to-concrete except for a coating of asphaltic material; vertical joints were provided with a 1-in. spacing which was filled with asphaltic compounds to permit lateral movement.

To compensate for probable settling the crest of the dam was crowned to a maximum of from 6 to 7 ft. above the theoretical crest line. To take care of down-

Maximum cross-section of Salt Springs dam

stream settling resulting from reservoir water pressure the upstream face was designed and constructed with an upstream convexity in plan. For similar reasons and to prevent possible buckling of the concrete face, the face was concave to the water surface in vertical section. The facing contains about 30,000 cu. yd. of concrete, has an area of about 9.2 acres, and is anchored to concrete cut-off walls extending vertically from 5 to 25 ft. into solid granite. Grout holes extend some 50 ft. below the bottom of the cut-off wall.

Salt Springs reservoir has a capacity of 130,000 acre-ft., is 4 mi. long, has a maximum width of 0.75 mi. and floods 925 acres. A spillway with a crest length of 625 ft., channeled in the south side of the gorge adjacent to the dam, has a capacity of 48,000 sec-ft., providing a capacity of 300 sec-ft. per sq. mi. of drainage area with a freeboard of 8 ft.

Outlet works at the north end of the dam consist of two 10-ft. steel pipes inserted into the downstream end of a 19-ft. concrete-lined tunnel, built originally as a diversion tunnel to facilitate construction of the dam. Each pipe is provided with a 129-in. hydraulically operated butterfly valve and then is extended on into the river channel where it ends in a 78-in. butterfly valve designed for free discharge. These valves are provided to permit unwatering the reservoir at the rate of approximately 10,000 acre-ft. per day in case of emergency, and are designed for a maximum head of 275 ft., making them the highest-head free-discharge butterfly valves yet installed.

A branch from one of these pipes forms the 8-ft. penstock to the generating unit installed in Salt Springs power house a few hundred feet downstream from the dam. A branch from the other pipe ends in a 54-in. needle valve in which is incorporated an energy absorber of the through-baffle type which discharges into the power house tailrace forming a bypass to supply water to the Tiger Creek conduit, (which heads in the tailrace) when the Salt Springs unit is shut down or when it is operating under reduced head.

Bear River Water Supply

Bear River, one of the principal tributaries of the Mokelumne River, falls at a very rapid rate from a drainage basin high in elevation, the fall in the last 6 mi. above its junction with the Mokelumne being more than 2,500 ft. A projected 200-ft. dam will form a new Bear River reservoir, adding 34,000 acre-ft. to the storage capacity. Through a tunnel approximately 2.5 mi. in length this will serve a generating unit to be placed in the Salt Springs power house. The junction of the penstock and tunnel will be formed in a surge chamber to be excavated in solid rock, with a crest elevation above high water in the projected lower Bear River reservoir just mentioned. This will permit the water from Cold Creek, (a stream adjacent and similar to Bear River but lacking in storage sites) to be diverted through this surge chamber to serve either the Salt Springs unit or for storage in the lower Bear River reservoir. Any spill from these sources may be stored in Salt Springs reservoir. The arrangement is ideal from the standpoint of ease in using the runoff from the different sources and insures complete conservation of all water resources for maximum usage.

Salt Springs Power House

Salt Springs power house will be unique in that its two generating units will be radically different in design. Two sources of water are available to this plant: the water released from storage in Salt Springs dam under a static head of 244.5 ft., and water released from storage in lower Bear River reservoir under a static head of 2,089 ft. In the first case the head and water quantities require the installation of a Francis-type turbine, while the latter can be utilized only through an impulse wheel. In general, a vertical turbine with its draft-tube setting requires a power-house floor level considerably higher above tail-water elevation than is desirable with an impulse-wheel installation; hence, to maintain the power house floor on a single level, the cooperation of the turbine builder was sought in the final designs and the unit was constructed to permit its setting at an elevation which also would accommodate the impulse wheel. Although the high-head unit will be installed at a future date considerable progress in the preliminary design of the impulse-wheel unit was required to determine with some degree of accuracy what its probable dimensions would be. This also required cooperation with the waterwheel builders. Preliminary designs were all based on the desire to secure a plant which would make for convenience in operation.

The Francis-type turbine is a vertical-shaft unit designed to pass 550 sec-ft. at heads as low as 175 ft. in order to accommodate the lowered level of water behind the dam as storage is withdrawn. In effect, to maintain full load on the generator this requires a turbine which must be operated at part gate under maximum head conditions and with gate openings increasing as the head falls. At heads less than 175 ft., water will be bypassed around the turbine into the tailrace to maintain the conduit flow at full capacity. The turbine is rated at 13,500 hp., 300 r. p. m., and drives a vertical-shaft waterwheel generator rated at 11,000 kva., 11 kv., 60 cycle, 0.85 power factor. The generator is mounted on a concrete pedestal above the turbine and is totally enclosed with surface air coolers arranged at four points around its circumference. Contrasted to this will be the horizontal shaft unit installed to utilize the water from Bear River, an overhung impulse unit capable of developing approximately 35,000 hp. at 300 r. p. m. to drive a generator having a probable rating of 30,000 kva., 11 kv., 60 cycles, 0.85 power factor.

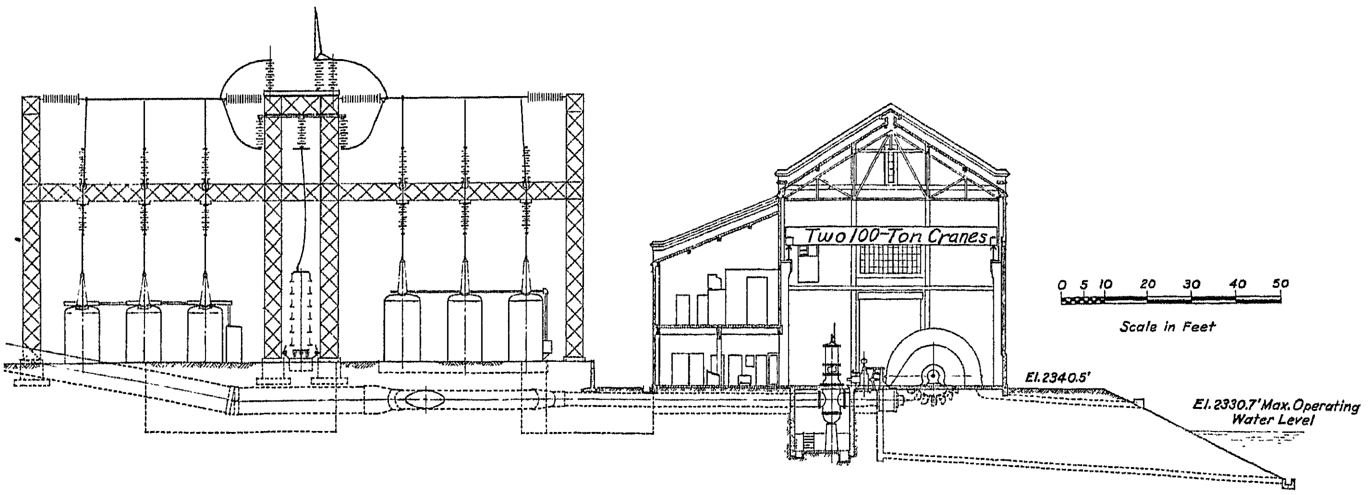
Both units will discharge into the same tailrace which forms the intake for the conduit supplying water to Tiger Creek power house. The capacity of the Tiger Creek conduit is 550 sec-ft. and it is desired to maintain this flow practically constant to supply water to Tiger Creek power house downstream. At full load the Salt Springs turbine unit will pass 550 sec-ft. and deliver power up to the 11,000-kva. rating of its generator, while the impulse unit will pass approximately 180 sec-ft. and deliver power up to the full rating of its generator, about 30,000 kva. Thus it is seen that by properly adjusting the load between the two generating units in the plant it will be possible to maintain a constant flow in the conduit at plant outputs which will vary between the limits of 11,000 kva., or less, and 37,500 kva.

At Salt Springs each generator is connected to a main bus through a single truck-type oil circuit breaker. Two similar breakers, so arranged as to be interchangeable with the main generator breakers, feed power from the main bus into the station power transformer bank. The added cost of the extra large breakers thus required for the service demands was greatly offset by the simplicity of the arrangement and the possibility of taking any oil circuit breaker out of service for inspection or repairs without any loss in plant output. From the main 11-kv. bus, leads run direct to a bank of three 12,000-kva., 11/110-kv. water-cooled transformers. A spare transformer may be substituted for any unit in the bank by means of air-break selector switches. Output from bank is fed through a 115-kv. oil circuit breaker into a single-circuit steel tower transmission line for delivery to the main 220-kv. transformer banks at Tiger Creek power house.

Tiger Creek Conduit

The 17.3-mi. Tiger Creek Conduit terminates in a regulating reservoir on Tiger Creek from which a 625-sec-ft. conduit extends 2.6 mi. to a 40-acre-ft. forebay at the head of the Tiger Creek penstock. The conduit is composed chiefly of a reinforced concrete flume with a water section of 84 sq. ft. and a water depth of 6 ft. In addition to the flume there are two 93-in. steel siphons totaling 0.23 mi. in length, and 2.5 mi. of 10 x 11.3-ft. unlined tunnel.

Topography in the vicinity of the site chosen for



Section through Tiger Creek power house parallel to penstock the Tiger Creek power house did not offer any suitable location for a forebay of sufficient capacity for the regulation of flow in the conduit and the carrying of peaks of short duration. Accordingly, a compromise was made by the creation of a pond known as the Tiger Creek regulator, about 2.6 mi. upstream from the forebay site, formed by a buttressed-slab concrete dam approximately 100 ft. high on Tiger Creek. The upper 18 ft. of the reservoir thus formed provides a storage capacity of about 175 acre-ft., sufficient to permit peaking Tiger Creek plant for 20 hr. each day when full diversion is being made into the head of the Tiger Creek conduit. About 30 min. are required for water released at the regulator to reach the forebay, and the available capacity in the forebay is sufficient to provide peaking during this interval.

Automatic gates at the outlet of the regulator reservoir maintain a constant flow in the conduit regardless of the height of water behind the gates discharging into the canal. Leads from the float controls have been carried to the switchboard room in Tiger Creek power house, enabling the operator to maintain any desired rate of flow between the regulator and forebay. The design of this automatic gate control equipment was perfected several years ago in connection with the control of water discharged from the afterbay at Pit River No. 3 power house where it has performed in every respect exactly as planned.

TIGER CREEK POWER HOUSE

The penstock consists of a single 4,750-ft. steel pipe varying in diameter from 102 in. at the top to 72 in. at the Y outside the power house. About 4,000 ft. of the upper portion of the pipe is of riveted steel with rivets countersunk on the inside of the pipe; the lower portion is seamless. At the Y the pipe branches into two 52-in. lines and again into four 36-in. lines to serve the four impulse wheels of the two double-overhung units.

Tiger Creek power house is the controlling station for the 220-kv. transmission lines constructed to receive the power generated by the waters of the Mokelumne River and to transmit it to the load centers at Newark and Herndon. To charge the 109-mi. 220-kv. line between Tiger Creek and Newark requires approximately 25,000 kva. which made desirable a minimum capacity for each generator of not less than that amount. Experience has indicated that it is much better to be able to charge a transmission line with a single unit than to attempt this function with two units in parallel. The extremely low excitation of the generator at times of charging an unloaded transmission line renders the parallel operation of generators unstable and makes their control exceedingly difficult. For this reason plant operation is very greatly facilitated if a line which is taken out of service for any reason can be charged from a single unit. Also it renders unnecessary the unloading of a second unit in order to make it available for line-charging purposes.

Static head and water quantities available at Tiger Creek indicated that the plant should have approximately 60,000 kva. in generator capacity, indicating at once that a two-unit layout was the proper one. Each waterwheel unit was designed to deliver 36,000 hp. at 225 r. p. m. under a net effective head of 1,190 ft. Generators are rated 30,000 kva., 11 kv., 60 cycles, 0.85 power factor. These waterwheel units are well up towards the maximum size practical for the head and water quantities available at Tiger Creek and in physical dimensions rank among the largest impulse wheels ever constructed.

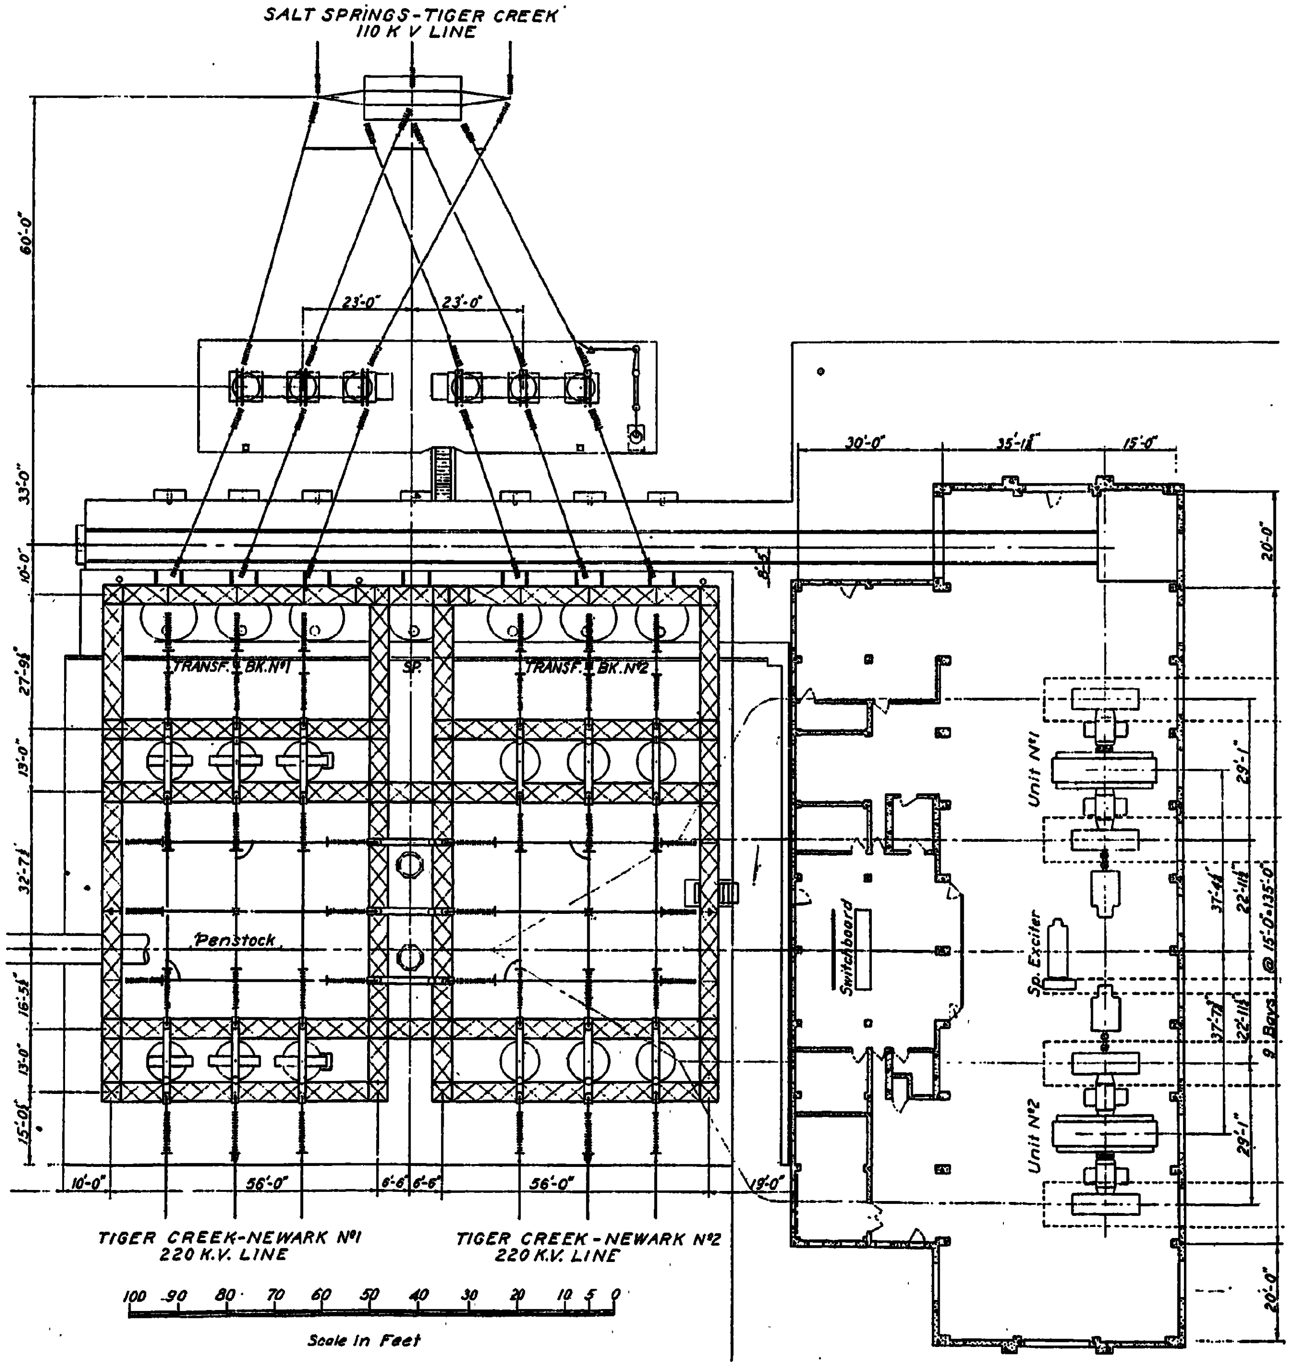
Many refinements have been incorporated in the design of the wheels. A straight-flow needle nozzle has been designed introducing into the water flow a minimum disturbance, thus giving a uniform, compact jet delivering maximum power to the waterwheel buckets. The power needles are operated by the governor servomotors and, as a water conservation measure, are arranged for slow closure upon load rejection in much the same manner that the relief valve closes on a large hydraulic turbine installation. Linked with the governor and needle-operating mechanism is a jet deflector in the form of a collar surrounding the jet which operates to remove water from the wheel instantly upon load rejection. The combination of jet deflector and slow-closing needle is ideal for an impulse-wheel installation in that it makes possible the quick diversion of water from the wheel without disturbing the flow in the penstock with its attendant surge. This permits economies in the installation through reduced penstock cost and the omission of a surge chamber.

Simplicity of plant layout was the aim throughout the design of Tiger Creek power house. Each generator with its associated step-up transformer bank is considered as a unit; there is no oil circuit breaker between the generator and the low-voltage side of the transformer. The electrical connections are extremely simple. A steel bus structure containing four 11-kv. truck-type oil circuit breakers is installed in the bus room, two of the breakers serving to connect the generators to an 11-kv. bus for the purpose of synchronizing before closing the main 220-kv. breakers. When the units are in parallel on the high-voltage side of the transformers, one of these breakers is opened separating the units on the generator side; the other remains closed to supply power for station requirements. The remaining two truck-type breakers are for the station power transformer bank. As at Salt Springs, these four breakers are interchangeable.

Each generator is provided with a direct-connected exciter and pilot exciter both controlled by voltage regulators. A spare exciter set is installed between the main generating units and arranged to be driven either by an impulse waterwheel or an induction motor. Each waterwheel has its individual governor oil pressure system with duplicate oil pumps, one motor driven and the other driven by a small impulse wheel. For normal operation the motor-driven pump maintains the oil pressure, but suitable controls have been provided so that any failure of supply from the motor-driven pump automatically will start the water-driven pump to reestablish governor oil pressure.

The switchboard is in the switch and bus section of the power house on the level of the generator floor and midway between the units. To facilitate operation all equipment requiring frequent attention has been installed on the main power house floor, and considerable thought has been given to the convenience of the location of equipment from an operating standpoint. Equipment requiring infrequent inspection has been placed on the second floor of the power house and the general layout of the plant has followed the idea of making operation possible with a normal shift consisting of a first and second operator. The duty of the first operator will be the switchboard, while the second operator will be available for oiling and operation of the disconnecting switches in the outdoor switch yard.

The two banks of step-up transformers have combined double and auto-transformer windings, each



Plan of Tiger Creek power house and bus structure

bank providing both a 30,000-kva. capacity for stepping up the incoming power from Salt Springs power house from 107.5 to 215 kv., and a 30,000-kva. tertiary capacity sufficient to care for one Tiger Creek generator. The transformer banks therefore will have a total capacity of 60,000 kva. each. A spare unit is arranged for emergency substitution in place of any of the six regular units.

To regulate water discharge from Tiger Creek plant for diversion to the next lower plant, an afterbay has been provided by constructing in the Mokelumne River some 2 mi. below the plant a concrete arch dam about 100 ft. high. This dam caused the flooding of about 100 acres, creating a reservoir of 300-acre-ft. capacity in the top 3 ft.

West Point Power House

The last of the four power houses in the Mokelumne project, but the one immediately downstream from Tiger Creek, will be known as West Point power house, the location and construction of which was influenced by the existence of the present Electra power house. Diversion of water for West Point will be made from Tiger Creek afterbay about 3 ft. from the top of the dam into a 4-mi. conduit which will connect with the West Point penstock providing a 285-ft. static head. No forebay facilities being available, the plant will be designed to operate at 100 per cent load factor with a maximum flow of 575 sec-ft. A single vertical turbine driving a 15,000-kva., 11-kv. generator will be installed and the plant will be laid out for full automatic operation, with certain controls carried back to Tiger Creek power house. Generated power will be stepped up to 60 kv. to supply the demands now served by the present Electra plant, making West Point the only plant on the Mokelumne system not regularly feeding into the 220-kv. transmission system.

Electra Power House

Construction of the new Electra power house and conduit will follow immediately upon the completion of the Salt Springs-Tiger Creek development—probably in the fall of 1931. The static head to be developed at Electra is 1,265 ft. and the water flow 575 sec-ft. The two waterwheels will have a slightly greater horsepower rating than Tiger Creek, 37,500 hp. each at 225 r. p. m., but their almost identical physical dimensions will permit the construction of a duplicate power house. One factor is present in the Electra designs which was not at Tiger Creek; the presence of an excellent 1,158-acre-ft. forebay in Lake Tabeaud. This will permit considerable peaking at Electra and all designs are being made so that a third unit for peaking may be added later.

Power generated at Electra will be stepped up through two banks of transformers to 220 kv. for connection to the Tiger Creek-Newark transmission lines. It will be necessary also to provide for supplying power to the 60-kv. and 17-kv. systems now taking the output from the present Electra plant.

General

The peak load on the system of the Pacific Gas and Electric Company and associated companies reached 853,300 kw. July 1930. In the decade 1920-1930 the load on the system has grown at the average annual rate of 7.25 per cent, requiring the addition of some 40,000 kw. of new generating capacity each year. The new capacity was provided partly in steam-driven units and partly in hydro, the ratio of the two types of prime movers for the entire system up to 1930 being approximately two to five.

Prior to the advent of natural gas as a fuel in central California, and before the recent great increased steam plant economies, hydroelectric plants with their relatively long transmission lines were able to deliver power to the consumer at prices which made the development of the hydro resources of the state economically attractive. Now the picture has changed and natural gas has placed the cost of power from the two sources approximately on a par. A relatively slight variation either way in the cost of fuel may have great influence on the type of future generating equipment.

The power peak growth of the system for the next five years will approximate 50,000 kw. annually. This is favorable to hydroelectric power in that it permits full development of a river over a short period of time, thus dividing the cost of water storage among all plants on the stream and reducing the fixed charges per kw-hr. generated. In order to produce hydroelectric power on the most economical basis, hydro plants in California must operate on the highest possible load factor. The average annual load factor for the system of the Pacific Gas and Electric Company is approximately 62 per cent and all studies for the plants on the Mokelumne River, with the exception of the 100 per cent load factor plant at West Point, were on the basis of 85 per cent load factor. Such operation will be possible in each year with normal or above normal rainfall. Studies of runoff over a 24-year period have indicated that the average annual output will be 88 per cent of the maximum possible during the wettest year recorded, with a 47 per cent output during the extreme dry year. On the Mokelumne River normal plant operation will be on base load with system peaks carried by steam. This condition may be reversed on extreme dry years when the economic use of stored water dictates its use for the carrying of peak loads.

The total cost of the Mokelumne River development as here outlined, including transmission and the increased capacity at Newark Substation, is practically $39,000,000. The entire design and construction of the project have been carried out by the regular personnel of the Pacific Gas and Electric Company.

Power Distribution from Mokelumne Plants

To carry 150,000 kw. of hydroelectric energy from the mountains of California to the San Francisco Bay area and there distribute it, required the construction of an entirely new 220-kv. transmission system and the development of a one-time 60-kv. substation into a major system switching center interconnecting 60-, 110-, and 220-kv. lines.

Both of the
Pacific Gas and Electric
Company, San Francisco

As INDICATED in the preceding article which describes the power development features of the Mokelumne River project of the Pacific Gas & Electric Company (Calif.) one of the most unique features of the project was the fact that it required the building of practically a complete new system within a system already operating. The transmission and distribution phase of the project involved the construction of 17 mi. of 110-kv. single-circuit line to interconnect the upper two generating plants; the construction of 109 mi. of twin-circuit 220-kv. transmission line to a San Francisco Bay terminal station, the stringing of a 100-mi. 220-kv. intersystem tie line (on existing towers) and the creation of a 249,000-kva. dual terminal station providing intrasystem ties; and accommodating the two 220-kv. Mokelumne line, sixteen 110-kv. circuits, and three 60-kv. circuits.

In developing this dual substation, which is located at Newark, an unusual situation was involved. Other stations previously chosen as transmission line centers and designed with the idea of future expansion in many cases had failed to develop their expected importance due to the shifting of load centers or to changes in transmission voltage. Although not originally considered as likely to be greatly expanded, Newark station has grown through a step-by-step process (including the Mokelumne River project as a major part) into the largest and most important transmission center on the entire system. It is worthy of comment that in spite of the many additions and the changing importance of its position, the flexibility of the unit structures used has allowed it to develop into a rational arrangement.

As a result of an extended economics study and a review of the operating facilities involved, a nominal line voltage of 220 kv. was adopted. To facilitate future interconnection with the Vaca-Dixon substation (southern terminus of the company's 220-kv. Pit River system) the receiving voltage at Newark substation (the San Francisco Bay terminal station) was set at 200 kv. To enable the generators to operate at unity or lagging power factor and thereby require the high excitation essential for good stability, the voltage at the Tiger Creek end of the line was set at 215 kv., thus providing for charging current to be supplied from the receiving end.

TOWER DESIGN

The 220-kv. Mokelumne River transmission line starts from Tiger Creek power house switchyard at El. 2,400, terminates at Newark substation at El. 7, and in general involves two types of towers, two types of conductors, three different loading zones, and three zones of insulation.

In the heavy loading area, including the first 16 mi. of line out from Tiger Creek, there are two lines of single-circuit snow-type towers set in concrete foundations. These towers accommodate a horizontal configuration providing a 20-ft. spacing between conductors, and are designed for a loading of ½ in. of ice, and a wind loading of 6 lb. per sq. ft. at 0 deg. fahr. (Fig. 2.)

The next 11 mi. of line through the lower foot-hills are designed for a medium loading of ¼ in. of ice and a wind load of 6 lb. per sq. ft. at 0 deg. fahr. In that section of the line there are twin-circuit steel towers set in concrete foundations. These towers permit a semi-vertical configuration for both circuits, providing a 15-ft. vertical clearance between conductors, a 28-ft. horizontal separation between the top wires and the bottom wires of the two circuits, and a 38-ft. separation between the center wires. (Fig. 3–left.)

The remaining 82 mi. of line comprises the light-loading area where the design is based upon a wind load of 8 lb. per sq. ft. and 25 deg. fahr. In the upper 53 mi. section of this portion of the line, which crosses California's great central valley of the San Joaquin, the towers used are the same as in the previous 11-mi. section except that the middle conductors are not offset, the configuration being strictly vertical. The remaining 29-mi. section of line traverses a hilly country which is considered to be a fog area. In this lower section of the line the tower structures have the same steel below the crossarms as in the two-circuit structures of the previous section. With the upper tower design modified to provide a vertical separation of 18 ft.

From "Power Transmission and Distribution From the Mokelumne River Development of the Pacific Gas and Electric Company," (No. 31-131) presented at the A. I. E. E. Pacific Coast convention, Lake Tahoe, Calif., August 25-28, 1931.

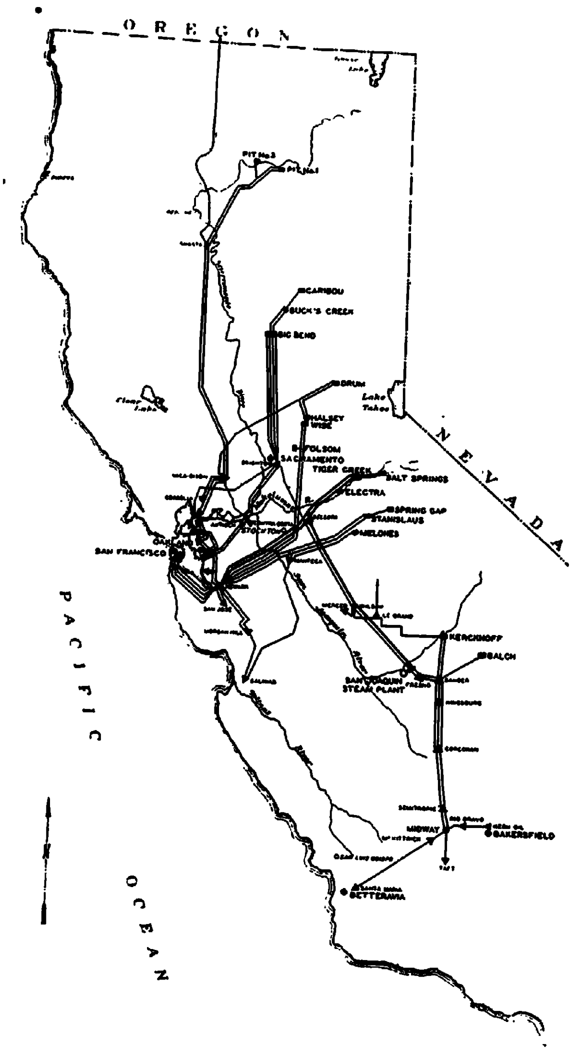

Fig. 1. Map showing the 110-, 165-, and 220-kv. transmission system of the Pacific Gas and Electric Company and the San Joaquin Light & Power Corporation

The Mokelumne circuits may be traced as the heavy lines starting at Salt Springs. The triangles indicate substations; the solid circles, major steam plants; the heavy open circles, proposed steam plants. Distances may be scaled at about 98 mi. per in. as shown

between conductors and a horizontal separation of 33 ft. between circuits. These larger spacings are used to permit the required increase in insulation. (Fig. 3-right.)

In the 17 mi. of 110-kv. line which interconnects the Salt Springs power house with the Tiger Creek power house, single-circuit snow-type towers set in concrete foundations accommodate a flat configuration of conductors providing a 14.5-ft. horizontal spacing between conductors. This line starts at El. 3,800, reaches El. 5,000 at about its midpoint, and terminates at Tiger Creek at El. 2,400.

Normal spans on the 110-kv. line are 600 ft. although there are several long spans ranging between 1,500 and 2,100 ft. On the 220-kv. main transmission line the normal span for snow-type towers is 600 ft.; for the twin-circuit towers 800 ft. Extra long spans in the 220-kv. line range from 1,000 to 1,800 ft. in length.

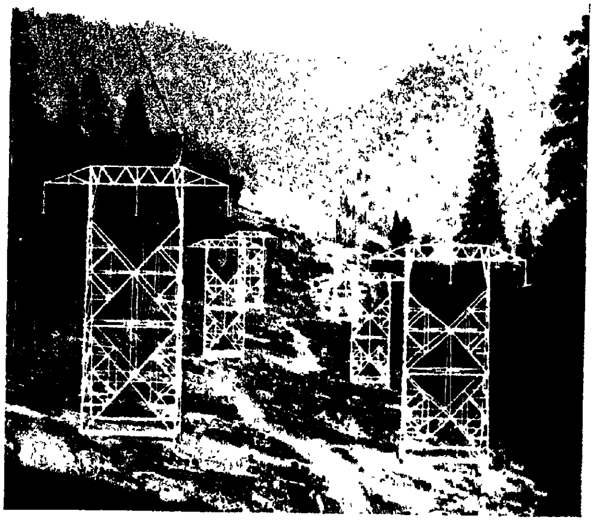

Fig. 2. 220-kv. tower line near Tiger Creek power house

Towers of the same type but of increased strength are used where necessity requires it, but no dead-ends or semi-strains are used unless required for angles, upstrains, or crossings. Transposition throughout are of the rolling type without dead-ends. (See Fig. 4.)

CONDUCTORS

As a result of extensive tests made at the Ryan laboratory, Stanford University (Calif.) two different standard types of cables were chosen for the 220-kv. line. Throughout the heavy- and medium-loading area comprising the upper 27 mi. of the line, 518,000-cir. mil steel-reinforced aluminum cable, having an outside diameter of 1 in., was selected. The stranded steel core in this cable is approximately 5/8 in. in diameter. In the lower 82-mi. section of the line where conductivity as well as corona loss were of primary importance, 500,000-cir. mil hollow-core copper conductor of 1-in. outside diameter was chosen. This cable consists of two layers of wires laid over a twisted copper I-beam.

With the aluminum cable, standard compression joints designed by the cable manufacturer were used, pressed on in the field for all splices. For the copper cable, screw joint splices were used comprising threaded lugs drawn on the end of the conductor at the factory, and connected in the field by means of a sleeve nut reverse threaded to obviate twisting the cable.

Standard bolted *J*- and *U*-bolt clamps were used on both the aluminum and copper, and both for section and dead-end construction, thus eliminating any cutting of the wires. Particular attention was paid to the choice of clamps for the aluminum conductor so that they would fit the conductor as closely as possible for not less than 80 per cent of its total circumference.

On the 17-mi. 110-kv. line above Tiger Creek plant, the normal conductor is 4/0, 7-strand medium-hard-drawn bare copper, except in some long spans where 4/0 "Hitenso" copper is used to meet strength requirements. All splices are of the drawn-joint type and were put on in the field with a portable draw-bench built for the purpose.

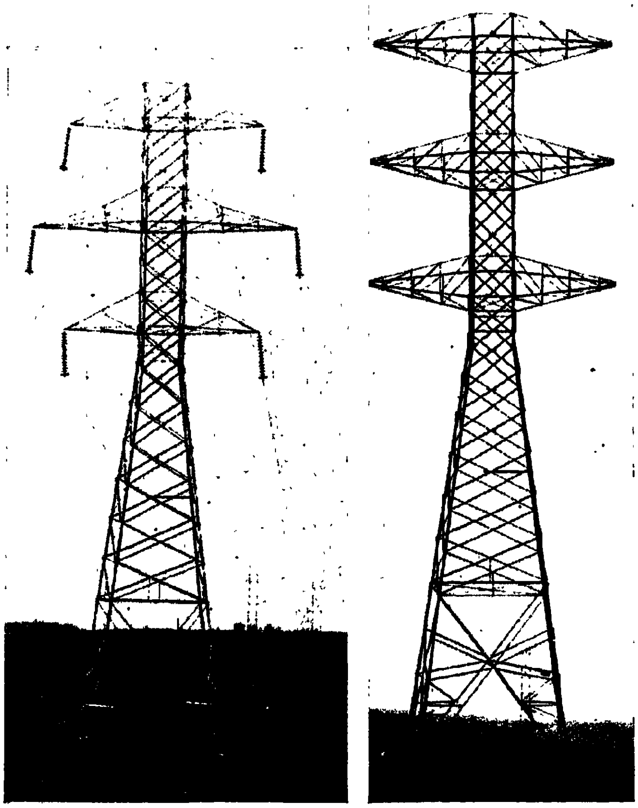

Fig. 3. Typical 220-kv. towers for medium-load area (left) and for fog area (right)

These have been reproduced approximately to scale to show the differences in relative dimensions. Careful scrutiny may reveal transposition towers in the distance (left)

INSULATION

Although ball-and-socket type insulators were used throughout on the 220-kv. transmission line, the gradations of insulation to meet local conditions divide the line in general into three sections: standard, light fog and heavy fog. The upper 79-mi. section of the line from Tiger Creek down across the San Joaquin Valley comprises the standard section, where thirteen standard-strength 10-in suspension type insulator units with 5.5-in. spacing in the suspension string, and thirteen high-strength 11-in. units with 7-in. spacing in the dead-end string, are used on both circuits.

In the two fog areas, depending upon the fog density expected, from seventeen to twenty standard insulator units are used on one circuit, and from eleven to fourteen fog-type units of two different designs are used on the other circuit. The lengths of the insulator strings of each type were laid out in proportion to the recommended insulating value. From an experimental standpoint this directly competitive insulation installation should reveal some very useful operating information as to the relative values of the standard and fog-type units under comparable and normal operating conditions.

On the 110-kv. line above Tiger Creek standard-strength suspension type insulator strings made up of eight 10-in. units were used for all suspension points, with nine units for most of the dead-ends. Where the strain was excessive such as at high points in the line, high-strength insulators in strings of nine 11-in. units were used.

BELLOTA-SAN JOAQUIN TIE LINE

At Bellota substation which is situated at a point about 42 mi. from the Tiger Creek plant, the 220-kv. Mokelumne lines cross the Feather River line. There both of the 220-kv. Mokelumne circuits are tapped to provide a feed into a single circuit which was strung about 100 mi. on the No. 2 position of the existing 165-kv. line connecting with the San Joaquin Light and Power Corporation's substation near Fresno.

The conductor used for this tie line is hollow-core copper of the same specification as that used on the

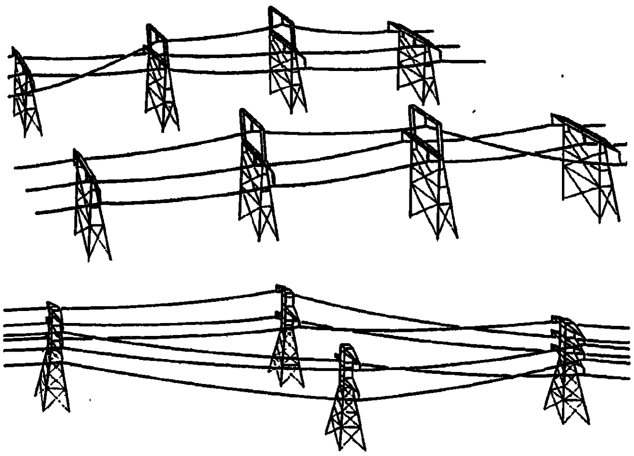

Fig. 4. 220-kv. transposition schemes

Mokelumne circuit. Insulation also is typical of Mokelumne specifications comprising fourteen standard units in suspension and fourteen high-strength units in dead-end string. A combined static shield and arcing ring is used on each insulator string. All of the switching at the Bellota substation will be handled by remote control from Stockton substation about 20 mi. away.

NEWARK SUBSTATION

Newark substation, the San Francisco Bay terminus of the Mokelumne transmission system, long has been the distributing point of Mokelumne River power (originally from Electra plant). However, growth to its present proportions was not expected when it was developed in 1919 as an ordinary 60-kv. switching and power distributing station. Nevertheless, as a result of the unit type of structure adopted in the original design of Newark station it has been possible to evolve a continuously modern station capable of handling the ever-increasing power concentration thrust upon it. With the advent of 150,000 kw. from the Mokelumne River development the principal of a dual station has been developed.

That an economical and yet flexible switching arrangement might be provided for handling the 220-kv. circuits, a double bus is used with bus selector air switches and a single oil circuit breaker for each transmission line, and transformer bank. With this arrangement a circuit can be connected to both buses, or to either bus, as switching requirements may dictate. The 220-kv. bus structure provides switching facilities for the operation of two transmission lines, three transformer banks, a bus-paralleling oil circuit breaker, and carrier-current telephone coupling equipment.

General dimensions of the bus structure are: length 354 ft., width 116 ft., height of center dead-end frame 64 ft. The structure is of galvanized steel. This design provides for the buses and selector switches to be placed well above ground elevation. The six 650,000-cir. mil concentric-lay copper cable conductors comprising the double bus are strung in tension, dead-ended at each end of the bus structure, and supported in between on the cross frame with pillar-type insulators at each bay. (Fig. 5.)

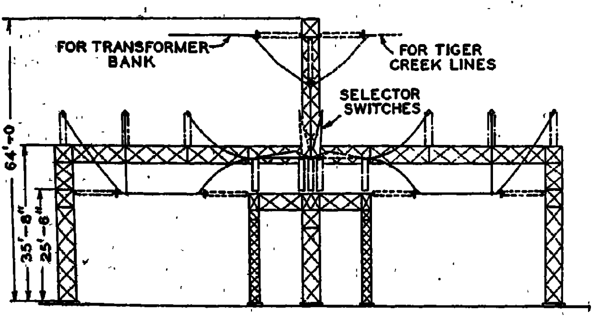

Fig. 5. Section through Newark 220-kv. bus structure

The 400-ampere selector switches are of the vertical-break type, each single-pole assembly of which consists of two single-pole air switches mounted on a common structural-steel base and insulated by five insulator posts per pole. The three poles of each selector switch are actuated by a single manually-operated control handle at the bottom of the supporting column adjacent to the switch assembly.

The two incoming 220-kv. lines and the bus tie breaker are accommodated on one side of the bus structure, while the three transformer banks are accommodated on the other side.

This arrangement of a 220-kv. oil circuit breaker complete with by-pass and disconnecting switches is similar to that employed at other 220-kv. stations of the Pacific Gas & Electric Company, (see Fig. 6) with the exception that a vertical-break by-pass switch is used instead of the so-called "roller-skate" switch previously used. Inverted switches of the latter type are used as disconnecting switches, however. On the towers which control the 220-kv. line, grounding switches are installed and mounted on the base of the by-pass switches. Grounding is effected by closing the grounding switch into a contact on the center post of the by-pass switch, subject, of course, to suitable interlock. All switches are actuated by means of rotary shafts and are hand operated. Within the galvanized tower structure is enclosed a 6-break

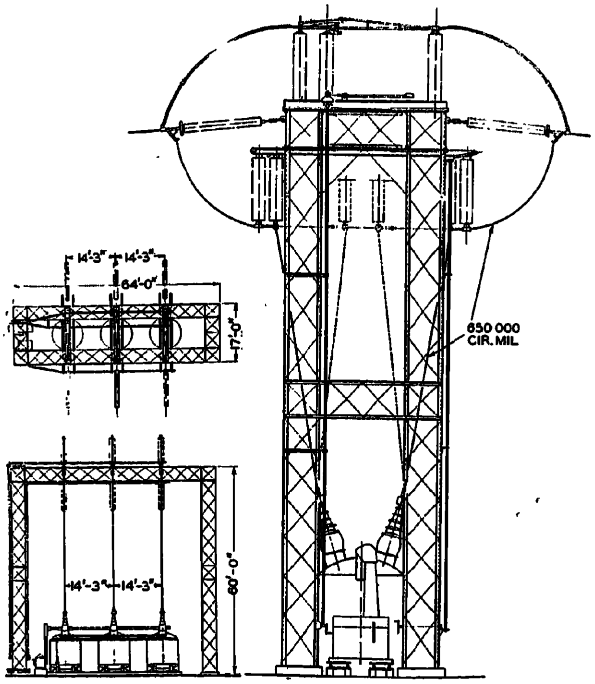

Fig. 6. Typical Newark 220-kv. self-contained switch structure

600-ampere 220-kv. oil circuit breaker mounted with the poles of the breaker on 14.25 ft. centers.

Each of the single-phase 200/110-kv. auto-transformers is rated at 18,000 kva. and is equipped with a tertiary winding to supply 11.5 kv. for synchronous condenser operation. Partial cooling is accomplished with radiators; additional cooling is obtained by means of hood-type radiator air-blast equipment. The transformer output at 110 kv. is delivered to the 110-kv. bus. One spare transformer unit is provided with a range which will permit it to be exchanged conveniently for any of the nine units in the three banks, which may require removal from service. To facilitate transformer handling a permanent handling house has been constructed and equipped with a traveling crane and all necessary tackle for untanking.

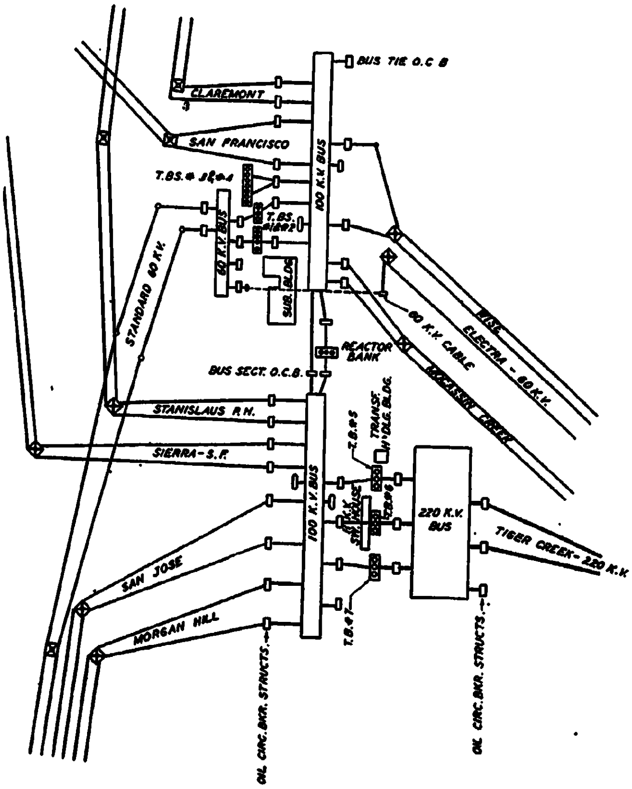

Fig. 7. General arrangement of Newark substation

Although it has developed far beyond original expectancies, the unit-type of structures consistently used have enabled the evolution of a very orderly and logically arranged station

The 110-kv. double bus also provides the single circuit breaker and switching arrangement described for the 220-kv. bus. The buses and selector switches are mounted on a rigid steel framework with all live parts well isolated by elevation. The bus conductors consist of 2-in. outside diameter, 14-gage copper tubing. Both the bus and the selector switch insulators are pillars made up of two 4-part units per post, each unit being 20 in. high. The 110-kv. bus is divided into two sections, and provision is made for controlling twelve circuits in each section.

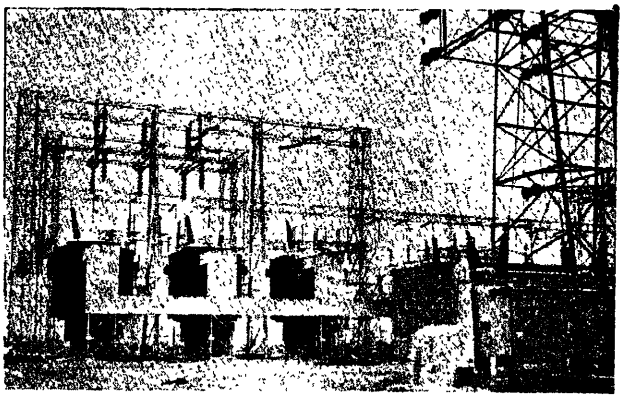

Fig. 8. Rear elevation of the 220/110/11-kv. Newark transformers

Because of the large power concentration now effected at Newark, current limiting reactors have been installed in one of the buses between the bus sections. (See Fig. 7.) Each of these single-phase 110-kv. 5,400-kva. reactor units is rated at 60 ohms reactance, and 300 amperes continuous duty, with an overload capacity of 1,060 amperes for three sec. Attention is called to the fact that this substation is essentially two stations, the dividing line being the reactor bank between the 110-kv. bus sections. One part comprises the older equipment consisting of several 110-kv. circuits, and transformer banks feeding 60-kv. circuits and synchronous condensers. The second part of the station comprises the new 220-kv. bus, together with the associated 220/110-kv. transformers, 110-kv. circuits, and related synchronous condenser equipment.

Consistent with the dual station principle it was necessary to make the switchboard in two sections, each section arranged to control its respective group of equipment. Because of the large number of circuits involved it was necessary to use a bench-board and two vertical boards, one for the indicating instruments, and one for relay equipment. To reduce the over-all length required in the switchboard, equipment for two circuits is mounted on one panel, one circuit above the other. This arrangement accomplished the necessary longitudinal reduction, but required panels 100 in. high, instead of the more conventional 90-in. boards. The entire switchboard is constructed of ⅛-in. sheet steel.

Synchronous condenser equipment for the new station consists of two 25,000-kva. 720-r.p.m. 11.5-kv. three-phase, 60-cycle machines of the totally enclosed ventilated type equipped with surface air coolers. Pedestal bearings are provided with passages for cooling water in the bearing shells. For fire-fighting water at 25 lb. per sq. in. will be used, distributed through manifolds installed at the end of the stator frame around the air gap. Each condenser is provided with a main and a subexciter. One machine was built with a 1,500-hp. synchronous driving motor to provide a convenient means of line and relay testing. This feature is particularly applicable to Newark station with its three main transformer banks, because with such grouping a bank can be released for build-up tests without great impairment of effective station capacity.

Switching equipment used in connection with the operation of the synchronous condensers is of the metal enclosed type using truck-type oil circuit breakers, and motor operated disconnecting switches. All of this equipment is housed in a small building adjacent to the 220-kv. transformers with underground lead covered cables providing the connections between switching equipment and condensers.

In unifying the existing and new control equipment in a new switchboard room the problem incident to conduit arrangements required that the transfer of control circuits from the old station to the new be made without service interruption. This was facilitated to a large extent by use of a control circuit terminal room directly beneath the switchboard room. All switchboard wires and control circuits were brought to terminal blocks and all cut-over work and testing procedure correspondingly readily executed.

Carrier-current telephone equipment installed will provide for communication over the 220-kv. lines to Tiger Creek power house, and also furnish communication circuits over the 110-kv. lines to station *J* in Oakland, whence a wire line extension is made to the load dispatcher's office. Coupling condensers on the 110-kv. and 220-kv. buses are so connected that the dispatcher may communicate directly from Oakland to Tiger Creek power house without assistance from the Newark operator.

As pointed out above, Newark substation as it now is constituted stands as the result of many additions. In spite of this, however, the flexibility of the unit structures used has allowed it to develop into a rational arrangement, and except for the old switchboard just replaced, every structure, whether installed in 1919 or in 1931, is functioning in its logical location as part of a modern substation.

In view of the fact that it is impossible to make accurate predictions as to the location of future load growth and the routing of transmission circuits to supply this load, it becomes necessary to design and construct major transmission substations in such a manner that they can be extended readily in any direction without the necessity of moving existing equipment or giving the appearance of a patched up job. Proper thought given to the design of the original installation will permit the achievement of these aims even though the station grows far in excess of any preconceived ideas as to its probable future importance. Satisfactory operation under any circumstance requires a simple and easily followed arrangement of equipment.

Riverbend Steam-Electric Generating Station

THIS newest steam station of the Duke Power Company, Charlotte, N. C., was placed in operation in October 1929 with an initial capacity of 137,500 kva., about one-fourth of the expected ultimate. Each of the two generating units operates at 1,800 r. p. m. with steam at 425 lb. gage and 725 deg. fahr., delivering energy at 13 kv. Each of the four cross-drum boilers has 35,500 sq. ft. of heating surface and is designed for 500-lb. working pressure; maximum furnace heat liberation is 30,000 B. t. u. per hr. per cu. ft. of volume. Pulverized coal is burned; the supply being received by rail. With this station the steam-electric capacity of the Duke system passed the 50-per cent point.

Industry's New Responsibilities

In an older day those who failed to store their food at harvest time did not fare so well during the winter; now, those who fail to accumulate at least a moderate surplus during times of plenty suffer accordingly during the cyclic "depressions." A thoughtful industrial leader, himself once a farm boy, here makes some interesting comparisons.

By
A. W. ROBERTSON Chairman of the Board
Associate A. I. E. E. Westinghouse E. & M. Co.

IN ITS BEGINNING this country was sparsely settled—dotted with small isolated communities tied together by waterways. Even the post roads were impassable a large part of the year. Not until 1830 did the railroads make their appearance. In 1885 the electric street car superseded the old horse cars and shortly thereafter we saw our great interurban development. The next step forward in transportation was in 1900 which marked the start of the era of the automobile. Since that time the transformation in our manner of living has been almost unbelievable.

The Passing of Individualism

It is interesting to note the shift in responsibility from the individual to industry which has taken place, even in the short space of my own life. In our early days we were tremendously individualistic. That was a basic characteristic of the founders of this nation. Every one stood on his own feet, or tried to do so, and was proud of his efforts. Each family was a group of home industries complete and almost self-supporting. Little had to be bought from the general store. Almost everything used was produced by the family. The women wove the fabrics for clothing from the wool, cotton, and hemp raised on the place. The men and boys were their own carpenters, blacksmiths, and shoemakers.

My father expected to take care of himself and his family without asking for help from anyone. He did it largely by working hard all during the spring, summer and fall. He loafed, or at least did not work so hard, during the winter. In the fall I remember we used to imitate the thrifty squirrel and stored up a supply of food to last until spring. With wood and coal in the shed, potatoes and other vegetables in the cellar, sausage, ham, and corned beef available in the meat-house, we faced the winter season of unemployment with something considerably less than dread—in fact, if I caught the spirit correctly as a boy, we really enjoyed it.

These were my personal experiences as a boy and they may not be typical of this whole country especially in the larger cities. Yet I have found them duplicated by so many other people who were reared as I was that I am inclined to think that my boyhood life represents a common picture of the independence of the individual of earlier generations. It was perhaps inevitable that this point of view should change—but it will be too bad to lose it entirely.

From Agriculture to Industry

After the Civil War in this country we commenced to be less and less an agricultural people and more and more an industrial nation. With the coming of mass production in the last thirty years, and other changes incident to it, population became congested in great cities.

Today the average home-owner has no place in which to store fuel or food beyond a supply for a short period. Gone are the days when the unit of purchase was a barrel of flour, a barrel of sugar. The unit of purchase is the smallest available package. Chain stores are conveniently located at almost every city corner and country cross-road. The railroads, trucks and passenger cars have made the distribution of goods both easy and quick, and it has been estimated that even in a large city like New York there is available less than a week's supply of food.

The average family today exists from hand to mouth and would not know how to live otherwise even if it so desired. When the periods of unemployment come, whether they be seasonal as in the older days, or due to economic depression, the average man has no fuel or food stored away to keep him and his family alive and comfortable while he searches for work to do.

If he was thrifty when business was booming, he has a savings account which he can use in bad times to buy the necessary food and clothing and keep a roof over his family. Thousands of persons have savings accounts as the statistics bear witness, yet unfortunately it just does not seem natural for human beings to be thrifty and save money while they are earning it. Certainly it does not appear that they save money now as they used to save food and fuel against the winter time of need. As a result many thousands of people today have no resources beyond their immediate needs.

From booklet published by the Westinghouse Electric & Manufacturing Company and availabl upon application to that company at 150 Broadway, New York, N. Y.

THE BURDEN OF THE IMPROVIDENT

There seems to be the growing tendency to try to shift to the shoulders of each industry the burden of providing for those improvident individuals, employed by that particular industry, who are unable to care for themselves in times of need. In certain circles apparently serious consideration is being given to the paternalistic proposals that big business, or the government, assume many of the obligations formerly recognized by the individual as his own personal burden and his own responsibility. Some states have enthusiastically adopted pension bills for mothers, for widows, and for old people; other states are giving earnest thought and study to compulsory unemployment insurance.

Meanwhile industry as a whole has voluntarily done a great deal to relieve its workmen of more and more of their former responsibilities and obligations. Most progressive companies can boast of departments which provide education, housing, a bonus, insurance, savings, old age pensions, etc., for their employees. Many companies in going into this general welfare work have taken the advanced stand, and recognized the principle that a loyal, faithful employee, in addition to his daily wage is entitled to an opportunity to participate in some form, depending upon his relative position, in the financial progress of the company for which he works.

Many companies are assuming also a large part of the cost of providing for employees during the present period of unemployment. It has become the accepted practise to spread out the available work in the plants and factories among as many men as practical although the operating results may be uneconomical for the company. These things are mentioned merely as illustrating the acceptance by industry of this added burden of unemployment.

INDUSTRY FOUNDED ON SAVINGS

The tragedy of the situation lies in the fact that big business, having assumed all these additional tasks, is just about as helpless as the employee. Every industry is affected differently by depression. Seemingly none is immune. All are influenced to the extent of having income seriously curtailed, and, in many cases, profits entirely eliminated. No company, large or small, seems to be financially strong enough, or lucky enough, to prevent serious shrinkage of its liquid resources in times of depression.

Under such circumstances the management of every company in every industry is confronted with the difficult and serious problem of deciding what course should be followed. Assuming that every well-managed company accumulated out of earnings some surplus during prosperous times, the question arises immediately as to how this surplus should be used when times are not so prosperous. The company must conduct its affairs in such a way as to maintain its credit. There must be money with which to pay honest debts—otherwise, the company will soon cease to function and it will not be able to meet any of the many obligations which it has assumed.

In addition to the creditors and the employees, there are the stockholders who have equities to be recognized. As the owners of the business, they are partners in the enterprise. Their just rights should not be ignored. Sometimes it would seem, however, from the careless talk indulged in by those who are not well informed in fact or theory, that stockholders are not entitled to any consideration. Those who voice such unsound opinions overlook the fact that stockholders, generally speaking, are employees of the company itself or are employed by some other company. At least in part, they are dependent upon their dividends just as they are on their wages for their living.

The money these people have invested in securities has to a large degree made possible the very existence of industry. The holdings of the stock of a company often represents the savings which the shareholder has made against the inevitable rainy day.

An investment is the dedication of the surplus of today to the needs of tomorrow—the insurance of ready cash to meet some form of future emergency. If that is a correct definition of an investment it may take many different forms with different people.

After a fashion, the investment by the stockholder is comparable to the stores of food and fuel which were commonly made in more primitive civilization, such as, for instance, my own boyhood days. If the rights of security-holders are not to be respected, then investors generally will cease to put their savings into industry; and there will be no industry. Further, there will be no safe place to invest one's savings.

THE HUMAN EQUATION

I fully recognize that the employees are one of the real assets of a going business—in many cases its most valuable asset—and their well being is of prime importance. People are too apt to think of big business as a piece of automatic machinery—soulless. In my opinion, the reverse is true. Big business must be human if it is going to succeed permanently because what makes the wheels go round will always be human beings—employees who are investing part or all of their life work in the service of that institution.

Business generally recognizes that regardless of the millions of money that have been put into plants and machinery, the ability to earn profits on that investment depends upon the loyalty and the efficiency of the employees.

It has been said, in substance, that public good will towards a company and its products, while intangible working capital, has as distinct earning power as the plants, which would soon turn to lifeless material were it not for the livening infleunce of these intangible values which, in the final analysis, are the contributions of the employees of a company.

The management of every concern always has before it the problem of dealing fairly with all parties involved—giving due consideration, of course, to the resources at its command. In periods of depression the task is made extremely difficult because no one can predict with any accuracy the length of time the set-back may continue. Consequently the management of a company does not know how long the earnings may continue below normal and how long it may be necessary to lend assistance to its employees out of work.

A. Mutual Problem

In the years to come if the business of this country follows the upward curve of normal progress, as it has in past decades; and, if business flourishes with only occasional periods of depression and unemployment, then the recent burdens added to industry will not become too heavy. On the other hand, if these periods of recession come too close together and increase in severity, then industry may not be able to carry on its usual normal responsibilities of payments to creditors, wages to employees, dividends to stockholders, plus the added burden of supporting the individuals who cannot provide for themselves in times of unemployment.

It would be most constructive at this time if there could be developed a more tolerant attitude toward this problem on the part of both industry and the individuals involved. The whole world is afflicted by a new set of conditions. The right cure will be beneficial to every man, woman and child; therefore, any proposal that may lead to progress in that direction should and will, I am sure, receive open-minded consideration.

To me it seems highly desirable that we keep alive the old-fashioned individualistic spirit of looking after one's self. It is going to be our salvation. It is one of our greatest inheritances from the founders of this country. After all, no one is as much interested in me as I am in myself. If each and every one of us made it our principal business to look after himself as well as a reasonably prudent man should, there would not be so much required of either industry or the state. That is what I would define as constructive selfishness.

Economic Laws are Insuperable

The picture is not without its bright side. There is ample reason to be cheerful. This country will weather this storm as it has successfully weathered every other great economic disorder of the past. And each time business has emerged upon a broader basis and a more solid foundation. The element of time is our worry. If we knew definitely when things were going to turn for the better the battle would be won and industry could plan accordingly. The rest would be easy. Certainly the worst is behind us and there is plenty of evidence for those who will look, that in certain lines, at least, improvement has commenced.

If the whole is greater than the sum total of the parts in periods of prosperity then the reverse is certainly true in times of depression. Corporations being but aggregations of people are subject to the same economic laws as individuals. Those succeed who perform or serve acceptably, and those grow more rapidly and become the greatest who serve best.

There is no Shortcut

Let us face the present unpleasant facts calmly and with courage. Let us be honest with ourselves.

There is no panacea for the present ills of all industry—no magic formula by which miracles may come to pass. Business will not change overnight, but it will be better tomorrow or the next day.

The desired objectives may be accomplished only by hard, consistent, endless work by us as individuals. There is no shortcut and we all know that is the truth.

Stability of Transmission Lines

STABILITY of power transmission "between two power plants operating in parallel is of utmost importance in providing uninterrupted power supply during system disturbances and abnormal operating conditions which may be due to short circuits, switching, and a variety of other causes," states Alexander Smouroff (F'24) professor, Electrotechnical Institute, Leningrad, U. S. S. R., in introducing a recent manuscript dealing with the subject of static stability. This paper represents another mathematical contribution to the analytical solution of the transmission stability problem and, being written by a prominent foreign engineer, represents a point of view somewhat different from that of American engineers.

The inherent dynamic stability and the artificial stability of a system are discussed, and a method is given for the determination of the dynamic stability of a system. The application of the proposed method is illustrated by practical examples.

"Stability of Transmission" by Alexander Smouroff, professor, Electrotechnical Institute, Leningrad, U. S. S. R., from which the above brief abstract has been prepared, has been placed on file (in manuscript form) for reference in the Engineering Societies Library, 29 West 39th Street, New York, N. Y. The complete manuscript is available for reference or photostat copies may be obtained from the library.

The paper concludes with an appendix in which formulas are given by which the maximum power output for stable operation of each of two plants operating in parallel may be determined as a function of the phase-displacement angle between the induced voltages of both plants. These equations give a criterion of stability and should prove of value in determinations of this character.

Economic Loading of Generating Stations

The problem of properly loading generating stations has evinced a gradual but continuous advancement as knowledge of the characteristics of power station equipment increased and methods of interpreting these progressed. The increment method has proved to be the most economical scheme thus far introduced.

By
E. C. M. STAHL

Brooklyn, N Y.

CORRECT LOADING of generating stations has assumed increased importance with interconnections becoming common, especially since the operation and control of boilers now have reached a point where dependable station heat rate characteristics can be duplicated day after day. Application of the different methods of load division, however, is dependent essentially upon the character of data available. There has been gradual development and transition in varying degrees of accuracy, from the use of average operating performance data on a monthly, weekly, or daily cost per kw-hr. basis to methods which permit of properly combining the economy characteristics of related equipment so that load can be divided on a minute-to-minute basis and full advantage taken of the immediate load conditions of the boiler room, station, or system.

With the increased grouping of stations having quite different characteristics and the rapid introduction of new types of equipment, direct and accurate means of load division must be used to secure the best operating economy. In an interconnected group, individual stations do not necessarily follow the characteristic load curves of the system demand. Consequently there is a shifting of load factors and plant factors among the different stations so that the use of average input-output data has lost much of its value from the standpoint of correct load allocation.

Briefly the steps which should be followed in setting up system-operating economies are:

1. To provide the necessary capacity in operation to insure continuity of service throughout the system.
2. To select the necessary equipment for carrying load in the order of its effect on the best *over-all* system economy.
3. To divide the load correctly on the equipment which has been placed in operation.

At least eight methods of load division have been developed, and in a number of cases the different methods, for certain ranges of operation, result in identical loading. These methods are:

1. Average increment loading.
2. Base loading.
3. Valve loading.
4. Best-point loading.
5. Proportional loading.
6. Equal-efficiency loading.
7. Increment of B. t. u. to throttle loading.
8. Increment loading.

In a system where suitable equipment and personnel are available for testing accurately each piece of equipment, information can be obtained which will permit a very accurate analysis of the load-division problem.

To arrive at the correct equipment set-up and then the correct division of load on the equipment placed in operation, the characteristics of each piece of equipment associated with power production must be known. Operating factors based upon the behavior of the equipment under normal operating conditions must be applied. Operating factors, such as the circulating-water temperature, depend partly upon conditions beyond the control of the operating personnel. In most cases, however, proper maintenance and skilful operation will result in close agreement between test and operating results. With individual characteristics known, group and station characteristics may be developed from which the final solutions may be built up.

In combination with the station characteristics, system layout and load data must be taken into account. The major factors which must be considered are: the characteristics of the daily load, load duration, and occurrence curves; local and emergency demands; local restrictive ordinances; tie-line capacities, and experience with the reliability and stability of the electrical system.

With proper equipment available and station charac-

Written especially for ELECTRICAL ENGINEERING, based upon an oral presentation before the Power Group of the New York Section, A. I. E. E., New York, April 9, 1931. Not published in pamphlet form.

teristics known, not only can a correct solution of any momentary load-division problem be reached, but studies may be projected into the future showing the probable share of load which new equipment would receive, based upon contractual characteristics. The effect of new equipment on operating costs also may be predicted quite accurately. The result of allocating any subdivision of the system load for any station may be computed, and system operating results for any proposed method may be estimated accurately. After the correctness of the station heat-rate characteristics has been established from tests and operating results, these data may be applied to the derivation of instantaneous energy costs which in turn may be used as the energy element of the cost of load transferred from one station or system to another at different periods of the day.

The different methods of load division now will be discussed in approximately the same order named previously. Fig. 1 shows station characteristics taken from daily operating data and illustrates the *average increment* method of loading. Each point represents the integrated 24-hr. output for various station loads plotted against total B. t. u. input. Over a period of time a large number of values are obtained which give the average economy characteristic trend of the station. Straight lines may be drawn through these points as indicated for stations *A* and *B*, and from this information a determination may be made as to how to load the stations with respect to each other. It is evident that if a daily output of only 100,000 kw-hr. is needed, station *A* could carry the load with less input than station *B*; if the output were 400,000 kw-hr., station *B* could carry it more economically than station *A*. If both stations were required to be in operation, station *A* would be operated at its minimum capacity until station *B* was fully loaded; and then station *A* would be loaded. This method of loading in no way takes advantage of the minute-to-minute economy relation between the stations, but merely uses the average integrated characteristics. As a result a constant increment of input is required for any added output and this constant increment represents an average increment characteristic of the station.

The method of *base loading* follows directly from the foregoing as it gives load to the best station or machine up to its maximum capacity before any load beyond its minimum requirements is assigned to the next best station or machine. Within the limits of data available both of these methods are correct, but as will be shown later they do not result in the best economy. It would appear further from a casual inspection of the heat-rate characteristics (see Fig. 6) that the *base-load* method is the correct one; but again this is not the case.

In Fig. 2 is shown a group of heat-rate curves which will be used to explain *valve opening, best-point,* and *equal-efficiency* methods of loading. Heat-rate characteristics of the older turbines are such that their best economy is obtained just before the opening of the overload valves which bypass steam into some of the lower stages of the turbine. The points at which these additional valves open are shown rather clearly in the illustration, and their effect will be fully illustrated later in showing the progress made in methods of interpreting turbine characteristics.

In the *valve opening* method when several turbines are in operation, the turbine with the lowest heat rate will be loaded first to the point where the overload valve is about to open. The other turbines then will be brought up successively to a similar condition. As the load increases still further, the best unit will be loaded up to the next valve opening, and the process repeated on the other units until full load is reached on all equipment in operation.

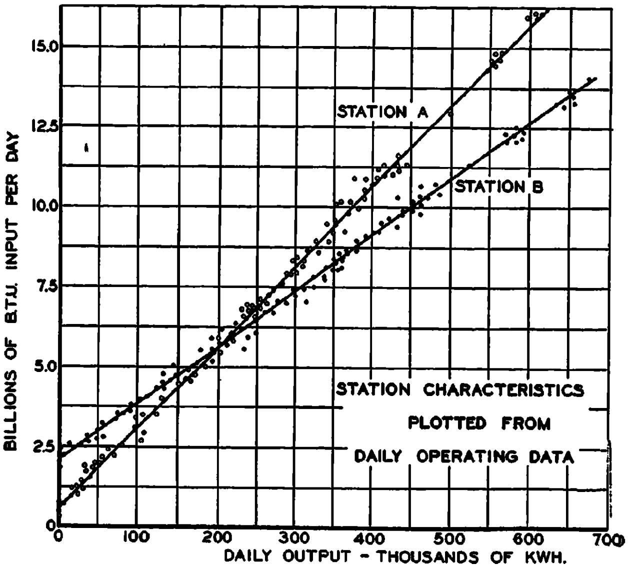

Fig. 1. Average characteristics for two typical stations as obtained from daily operating data

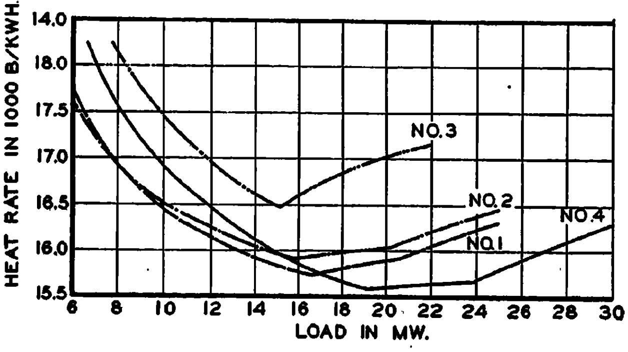

Fig. 2. Heat-rate curves for four typical turbines. Note the changing characteristics at the valve-opening points

Best-point loading in effect is quite similar to the *valve-opening* method but applies more generally to the total station heat-rate characteristics which include also the boilers. With this method, units or stations are loaded successively up to their lowest heat-rate points. In most cases, however, these coincide with the valve-opening points.

In the *equal-efficiency* method, the ratio of output to input of the various turbines must be equal, and in effect the unit heat rates also must be equal. Where this scheme is used, a schedule may be made up by maintaining equal unit heat rates on a variety of turbines, progressively as the load changes.

Fig. 3 shows a graphical layout for the method of *proportional loading.* This consists merely of plotting the sum of the turbine loads at their best heat rates and their full-load points, and connecting these points through zero with straight lines; from these, unit loads can be scaled off for any given station load.

Still another scheme is that known as the *increment of B. t. u. to the throttle* method. This is merely a special case of the incremental method, and has rather limited use where there is no bleed heating and where the characteristics between turbines are uniform.

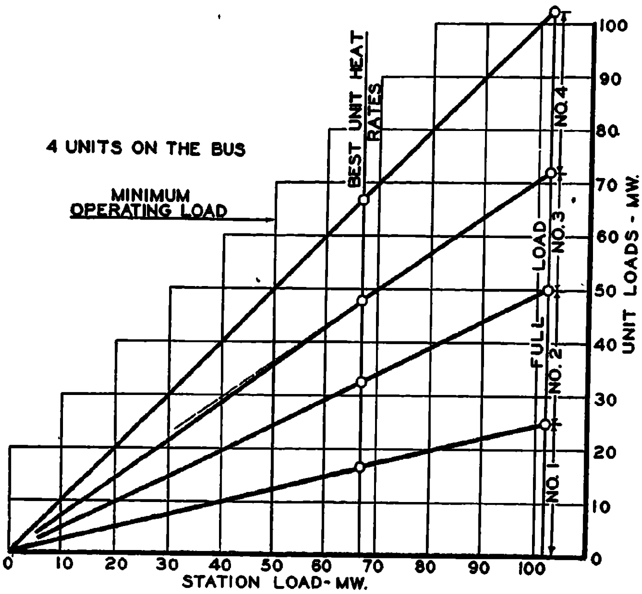

Fig. 3. Curves for establishing a proportional schedule of loading

Incremental loading, as the following discussion will bring out, results in the minimum input for any output with any given combination of equipment in operation. This method will not of itself show what equipment should be placed in operation, but with the aid of input-output data it will assist materially in determining the proper combination of equipment for various system- or station-loading characteristics.

Fig. 4 shows three stages in the chronological development of the interpretation of turbine characteristics and increment rates, the same test information being used in each case. Until about 1920 separate sets of points were plotted for the total input-output and for the unit heat rates, curves being drawn through the two sets of points independently. During the next five years the changing characteristics of the valve points were taken into consideration. As a result, the total input-output curve was drawn through the test points so that straight lines connected the test points for the separate ranges between valve openings. These lines were adjusted, however, to intersect at loads corresponding to the valve openings. The water-rate or heat-rate curves then were computed from the input-output curves.

In a more recent (1930) interpretation of test data the turbines are considered as having separate and distinct characteristics between valve openings. Entirely independent curves have been drawn through the various sets of test points between valve openings, and the unit heat rates computed from these independent sections. The corresponding incremental rates for the three schemes have been plotted and it may be noted that on the 1930 curve, the transition points have not been included on the incremental curve. From a practical standpoint this is not necessary because turbines are not operated near the valve openings,

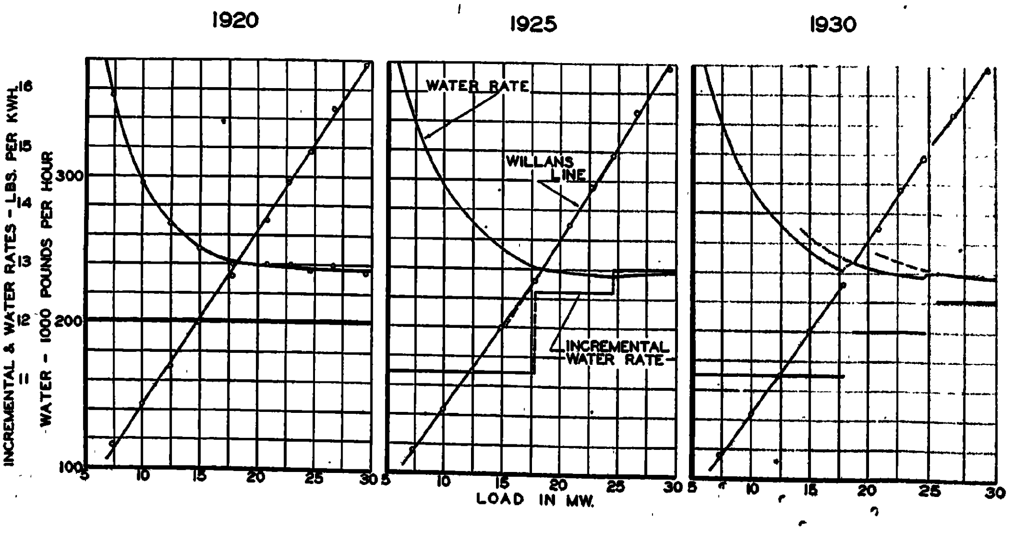

Fig. 4. Chronological development in the interpretation of turbine characteristic data

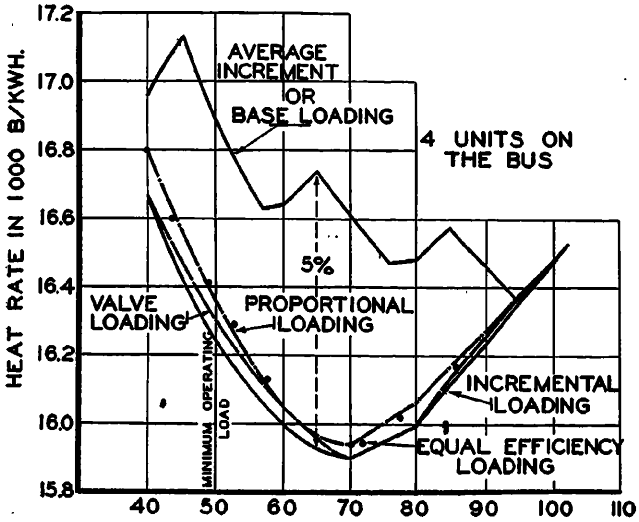

Fig. 5. Comparison of heat rates for the different methods of loading

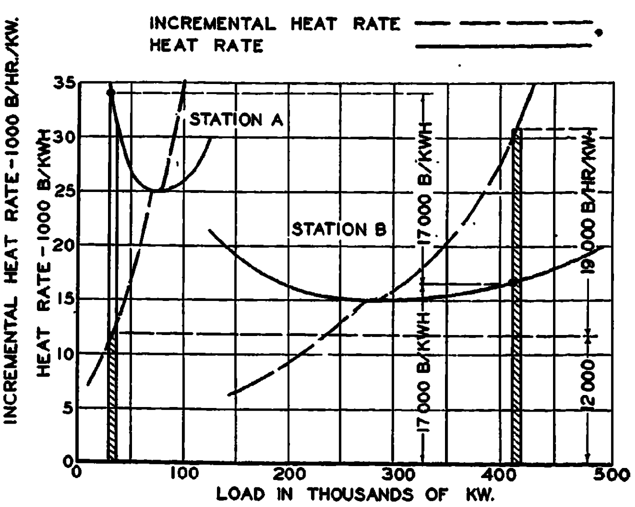

Fig. 6. Solution of typical load-division probl m by the increment method

The incremental heat rate at a given load already in production is defined as the actual additional heat per hour required to obtain the added load

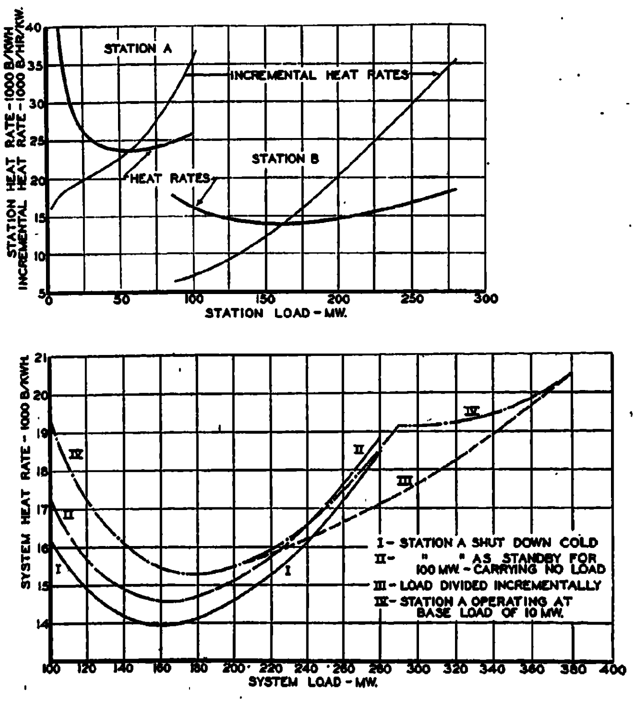

Fig. 7. Four methods of loading two interconnected stations having different heat rates

the operator passing substantially beyond those points. Again, justification for base loading of the best equipment is seen in the method used up to 1920, as a single straight input-output curve with a constant slope or increment is obtained which in itself justifies loading the best equipment or the equipment with the lowest average increment up to full load and then bringing on the next best.

A composite picture of the results of the various methods of load division is shown in Fig. 5. As would be expected the exact incremental method proves the most economical, while the average incremental or base loading method makes the poorest showing. The various other methods fall in between these two but generally nearer the exact incremental method.

The underlying principles of the incremental method are brought out by Fig. 6. Heat rates are indicated for two stations having 10,000 B. t. u. difference between their best points. Assume that the stations are so loaded that the heat rate of station *A* is exactly double that of station *B*. The question now arises as to which station should pick up the next 1,000-kw. load, assuming that the two are interconnected. From the heat-rate curves alone it would appear that station *B* should carry the additional load. It should be noted, however, that the heat rate is on the up-grade at station *B*, so that any added load would mean that its entire load would then be obtained at a higher heat rate and consequently the additional 1,000 kw. must contribute additional heat to raise the over-all heat rate of the station. On the other hand, an examination of the curves will show that the load on station *A* is such that if the added load were allotted to it, every kilowatt already in production would be obtained at a lower heat rate. At the points selected, station *A* can supply the added load to the system for 12,000 B. t. u., whereas station *B* would require 31,000 B. t. u. to produce the same load increment.

It may be noted that the dotted curves corresponding to the incremental heat rates are lower than the average heat rates while the heat rate curves are diminishing; that the incremental and average heat rates coincide where the average heat-rate curve is horizontal; and that the incremental rate is greater when the average is increasing. It can be proved mathematically and actually demonstrated that the most economical division of load is obtained when the incremental rates are equal.

As an example of a typical loading problem where two stations with different heat-rate characteristics are available, Fig. 7 illustrates the effect on system economy of operating the high-heat-rate station in different ways. Case I assumes that the best station alone is capable of carrying the entire load safely up to its full capacity, with the poorer station shut down cold. Thus if a system load up to 280,000 kw. were carried on station *B* alone, it would follow curve I. In case II it is assumed that station *A* is held with banked boilers, ready for emergency use in the event that station *B* might require emergency assistance. In this case the system heat rate would be represented by curve II. Case III goes one step farther than case II in that station *A* is maintained as a running reserve, with incremental division of load between the two stations. In this case the system heat rate would be as shown by curve III for loads above 2000,000 kw. In case IV station *A* is maintained as a running reserve as in case III, but the load between the two stations is divided by the base loading method. The system heat rate under these conditions would follow curve IV.

An interesting feature of the set of curves shown in Fig. 7 is that for loads above 240,000 kw. the system heat rate is lower with station *A* in operation than with it shut down cold. Should there be an appreciable number of kilowatt-hours to be generated at a system load higher than 240,000 kw., not only would the system be better protected by having station *A* in operation but the actual integrated heat rate would be better, as well as the instantaneous rate.

As supplementary to the foregoing discussion, the curves of Figs. 8, 9, and 10 are presented. Fig. 8 shows the heat-rate characteristics of a station with a given combination of boilers and various combinations of units in operation. For purposes of academic interest an average station heat-rate curve, such as has been used for the two previous demonstrations, is superposed on the group. Fig. 9 indicates the possible widespread variation in station heat rates, particularly of standby stations when the station plant factors and the capacity held available for emergency use are changed arbitrarily. Fig. 10 shows the general range of boiler and turbine characteristics in a large metropolitan district. The numbers opposite each curve represent the number of boilers or turbines observed to have the characteristics shown. For clarity, only a typical curve for each group has been drawn.

Basically, the problem of load division in a metropolitan area is a problem in thermodynamics. Ascertaining the principal characteristics of the equipment under operating conditions has become an extremely refined operation and is in itself a very large subject. The tremendous number of combinations of boilers and turbines which exist in any large interconnected system, the limitations imposed by the electrical system, and the ability of standby stations to be available instantly, make a complete solution extremely intricate. Instruments, however, have been developed to take care of the tremendous number of combinations once

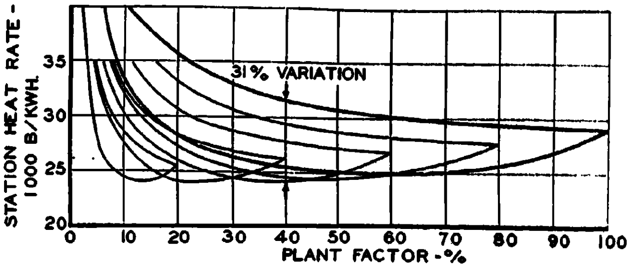

Fig. 9. Effect of peak plant capacity and load factor on station heat rate

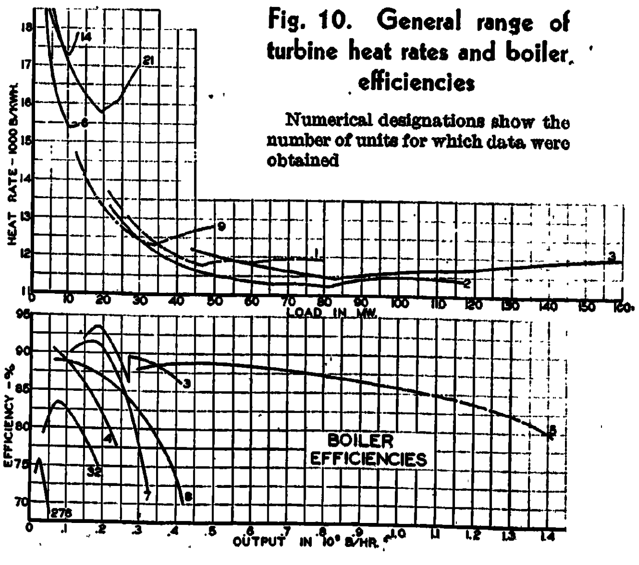

Fig. 10. General range of turbine heat rates and boiler efficiencies

Numerical designations show the number of units for which data were obtained

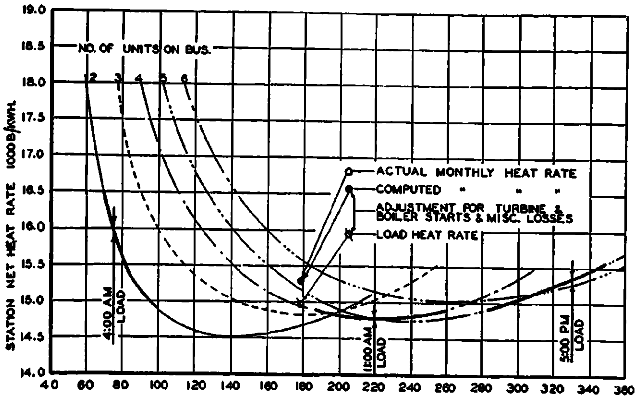

Fig. 11. Comparison between actual system monthly heat rate and computed value

the basic boiler and turbine characteristics have been determined properly.

Both the accuracy of the computations and the operation may be checked as shown in Fig. 11. This gives an illustrative group of station heat-rate curves as computed, and shows the computed monthly heat rate as compared with the actual monthly heat rate. The computed and actual rates may be seen to be practically identical.

By way of summary, the economic loading of generating stations possesses a wide variety of aspects all of which should be studied in order to arrive at a true perspective. The solution must be built up from individual equipment performance data in which the boiler characteristics play the most important part. This is particularly true when comparing two or more separate stations. It has been found also that obtaining accurate equipment characteristics has effects beyond the furnishing of data for load division and the establishing of "bogies" for operation. Manufacturers of large equipment have difficulty in checking their design practises without actual tests, and these can only be run after the equipment has been installed. Thus successive designs and guarantees may be based upon accurate information taken in the field rather than upon theoretical computation and extrapolated estimates. Furthermore, correct operating characteristics permit an estimate to be made of how well the system is being operated with respect to its possibilities, and this in turn gives assurance that no major improvement is being overlooked.

Basically, a load schedule should be set up on the assumption of unlimited tie facilities with no restrictions as to starting up or shutting down equipment. Schedules then should be set up adding successively the elements of safe operation of equipment, continuity of service, restrictive boiler-loading conditions, and tie capacity. In this way the cost of each inhibiting element may be determined. Such evaluations may be continued to take in the addition of new tie capacity, feeders, or station equipment.

The Engineer in Civic Affairs

Some of the features involved in the problem of "establishing a high professional standing of engineers in public affairs" are discussed here. Establishment of state and local engineering councils, and some means of "certification" of engineers by national professional societies are mentioned as steps toward a possible solution.

By
J. ALLEN JOHNSON Buffalo, Niagara & Eastern
Fellow A. I. E. E. Pwr. Corp., Buffalo, N. Y.

THE QUESTION of establishing and maintaining a high professional standing of engineers in civic and other similar affairs is one which requires limitation and definition to bring it within the scope of a single discussion. Three possible interpretations suggest themselves:

1. A complaint against public opinion because engineers' opinions on public questions are not given the respectful attention which engineers think they deserve.
2. A criticism of the engineering profession implying that professional standards are too low to cause engineering opinions on public matters to command public attention and respect.
3. An implication that although the profession and its standards are all right, a technique through which to make the profession authoritatively and effectively articulate on public questions is lacking.

If the first suggested interpretation were the correct one, and the effort were to devise ways and means of convincing the public that engineers should be listened to with greater respect when they deign to speak, I confess that I should have little sympathy with it. The time has passed when the professions had a monopoly on education. Nowadays an opinion on public affairs must run the gauntlet of well-informed persons in all walks of life, and must establish itself through its content rather than through its source.

Therefore, I shall assume that it is the engineering profession rather than the public which is to be scrutinized in this discussion, and that questions of both standards and methods are to be considered. In the subject thus defined there seem to be two questions involved:

1. How to establish a high professional standing of engineers.

A dissertation presented at the conference of officers, delegates, and members held at Asheville, N. C., June 22, 1931, in connection with the annual summer convention of the A. I. E. E. Not published in pamphlet form.

2. How to establish a high standing of the engineering profession in public affairs.

INDIVIDUAL IDEALS MUST BE HIGH

The attributes and responsibilities of these two aspects of professional life are well stated in an article on the "Professional Status of the Engineer" by W. E. Wickenden, president of the Case School of Applied Science (Cleveland) which appeared in the October 1930 issue of *Civil Engineering*. Dr. Wickenden states the following four attributes of individual professional life.

"1. A type of activity marked by high individual responsibility and dealing with problems on a high intellectual plane.

"2. A motive of service, as distinct from profit.

"3. A motive of self-expression which implies a joy in one's work and a single standard of workmanship; one's best.

"4. A conscious recognition of social duty to be accomplished, among other means, by: (a) sharing advances in professional knowledge; (b) guarding the standards and ideals of one's profession, and advancing it in public understanding and esteem; or (c) rendering gratuitous public service in addition to ordinary professional service, as a return for special advantages of education and status."

As a means by which individual engineers may attain a high professional standing I should recommend the conscious recognition and practise of these ideals which thoroughly express what should be the ethical and mental attitude of an engineer.

GROUP RESPONSIBILITIES

Doctor Wickenden also states the following as attributes of group professional life:

"1. A body of knowledge (science) and art (skill), held as a common possession and to be extended by united effort.

"2. An educational process of professional aims which implies a constructive share by the professional group in the ordering of education.

"3. A standard of qualifications for admission to the professional group, based on character, training, and competency.

"4. A standard of conduct in relations with clients, colleagues, and the public, based on courtesy, honor, and ethics.

"5. A recognition of status by colleagues or by organized society, as a basis of good standing.

"6. An organization of the professional group, based primarily on common interest and social duty rather than upon economic monopoly (not universal in the artistic professions)."

In addition to the obligation of the engineer to maintain a high professional standing as an individual there appears the obligation or desirability of establishing somehow this "recognition of status . . . . . by organized society" for the engineering group as a whole. Doctor Wickenden ably discussed this subject under the heading of four questions:

"1. Should we seek to divide the profession into distinct strata, or maintain an inclusive form of organization?

"2. Should we look to the public or to ourselves to set up and maintain our professional standards?

"3. Shall we narrow the doors of access to the profession?

"4. Shall we impose more rigid standards upon the colleges?"

THE MATTER OF ORGANIZATION

Under the first question would seem to come the problem of our own Institute organization. Should we have a single grade of membership or should we maintain the several grades? Much is to be said for the graded membership principle. In this country we have no aristocracy; no peerage. The result has been that for measuring one's attainments in life, no yardstick seems to be left but the financial one, a condition which I believe is largely responsible for the unfortunate American habit of measuring success entirely in terms of dollars and cents. Human beings seem to be possessed of an inherent desire to rise above the "common herd." Of those who fail to satisfy that desire by the acquisition of wealth, many seem to find satisfaction in the fraternal and social organizations with which this country is blessed (or cursed?) and get the satisfaction which they seek by attaining the distinction of election as "Kingfish of the Mystic Knights of the Sea," or perhaps as Fellows of the American Institute of Electrical Engineers. Personally, I believe that this sort of thing is a human necessity. Perhaps the field for its proper exercise is within the bounds of our professional and social organizations rather than in our civic life as a whole, but in my opinion a country which had *no means* of measuring the worth of its citizens other than by a dollar sign would be in a bad way.

Under the second question comes the matter of licensing engineers. In spite of the general opinion of engineers of high standing, that licensing is not the solution of the problem, we not only are facing, but even now are in the midst of the licensing problem. This subject already has been set forth in discussion and will not be treated here.

Under the third item again appears the question of professional society organization. Some have thought that we open our doors too wide and that higher qualifications should be required for admission to any grade of membership in a national engineering society. However, our principles and practises, as a society (A. I. E. E.) are long established in this matter and it appears doubtful that they should be changed at this late date.

Under the fourth question comes the problem of engineering education. While this problem has an important bearing on the broad question of the status of the engineer in the community, it is too large a subject to attempt to interject into this discussion.

IS CERTIFICATION THE ANSWER?

A solution of the problem of establishing for engineers "recognition of status by organized society" suggested by Doctor Wickenden is "the certification of engineers by our major professional societies." His proposal in this regard is worthy of being quoted in full. He says:

"Specifically, I should like to advocate one measure. It is in no sense a cure-all yet it would help in some degree toward the solution of each of the problems which has been discussed. This measure is the certification of engineers by our major professional societies. I would favor keeping the profession open, not making it a legal monopoly; and I would let licensing laws run their course until they find the level of their inherent limitations. I would keep our membership inclusive and not too rigidly graded, granting to engineers who pass into administrative duties the full fellowship of the profession. I should keep educational doors open to even greater variety, with a minimum of regulation and a maximum of guidance by the organized profession. All this is broad church doctrine in harmony with our history and traditions, and all good as far as it goes. But the profession needs more than an open association of like-minded men; it needs an inner nucleus of highly qualified men whose professional standing and standards the public cannot possibly mistake. A plan of certification by the profession is a task for many men to work out, not one. May I suggest, however, the following features:

"1. Certification should be earned, not granted as a mark of honor.

"2. There should be a code of educational qualifications more advanced than mere graduation from college and yet attainable by both college and non-college men.

"3. These qualifications should be tested individually, not gaged by personal estimates and testimonials alone.

"4. Educational qualifications should comprise scientific, technical, economic, and civic knowledge of a mature order.

"5. There should be a code of experience qualifications which would normally make the age of certification fall between 25 and 30.

"6. The certification of graduates should be the goal toward which the colleges and the professional societies should bend their influence. To this end the colleges should be encouraged to limit the award of professional degrees to those who previously have been certified."

Character Cannot be Inculcated by Statute

Here is a challenge to the engineering societies and the engineering profession as a whole which seems worthy of very careful consideration. It is no easy problem; the setting up of the necessary standards and qualifications for certification will be a long and difficult task, and the administration of the certification machinery after its establishment will call for men of the highest attainments and maturest judgment. And it all will cost money. If, however, the engineering profession decides that the results to be obtained will be worth the effort and cost, this seems to be a solution which would meet the desires and opinions of many of our members. I believe that its attainment, however desirable, is rather remotely in the future. Is there nothing that can be done in the meantime?

As to the licensing of engineers, doubtless some good can be accomplished if licensing laws are properly set up and administered, but as a means of separating the sheep from the goats in the engineering profession, I personally question the efficacy of inflexible statute laws. Character and ability cannot be inculcated by statute.

Is not the immediate problem that of "establishing machinery through which the opinions of competent engineers may be recognized, respected, and made effective in public affairs?"

In an attempt to answer this question, suppose we consider how we ourselves as "laymen" regard the opinions of lawyers, ministers, and others on public questions. In evaluating such an opinion, do we not subject it to critical analysis in the light of our own knowledge and judge it more by its content than by the standing of its authors? Particularly if the subject under consideration is one outside of the author's immediate specialized field.

Therefore an expression of opinion, whether by engineers or others, to be respectfully received by the public must either (1) be confined to a subject on which the author is a recognized authority, or (2) must contain within itself such evidence of breadth of view and sound judgment that it carries its own conviction.

Public Affairs Committees Suggested

Opinions by men of the engineering profession on matters of public interest rarely can be expected to fall in the first of these classes. Whence it would appear that the only way to make respected and effective the opinions of engineers on public questions is to establish some way by which such opinions can be made to bear on their faces the evidence of their own value. How can this be accomplished? How do we accomplish it in our own organization? If we wish to obtain a well considered and seasoned opinion on any engineering subject, standardization for instance, we appoint a representative committee from those best qualified to pass judgment on the matter. This committee meets, discusses, investigates, compromises, and ultimately arrives at a consensus of opinion which, when finally promulgated, is received with respect and usually accepted by the industry. If the engineering profession expects its opinions to be received with respect by the public this same method must be followed.

How, then, should such committees or groups be constituted? Obviously no one professional society can act alone in public matters; cooperation of all seems necessary. A start already has been made through the organization of The Engineering Council, a joint activity of the national engineering societies set up to deal with national affairs.

The next step in a logical development along these lines appear to be the establishment of state engineering councils to deal with engineering problems confined within state boundaries. Some action already has been taken in this direction.

Local Engineering Councils Logical

The third logical step would appear to be the formation of local engineering councils. Such councils already have been established in certain places and some of these are understood to be functioning successfully. Such local councils doubtless at first would have to be confined to the larger centers where local units of the national engineering societies exist, where they can be organized by joint action of such local groups. Possibly later on, means may be found to establish such local councils in smaller communities. To be useful to the community, such local councils should establish some sort of working arrangement with the local governing bodies.

Assuming then that the immediate solution of the problem of making the opinions of engineers respected and effective in public affairs lies in the formation of national, state, and local engineering councils, how can the A. I. E. E. promote the formation of such groups? I advance the following suggestions:

1. By gathering information on existing local and state engineering councils.
2. By establishing a standing committee to promote, oversee, and advise such local councils in cooperation with similar committee in other national societies.
3. By formulating preferred courses of local cooperation between A. I. E. E. Sections and units of other national societies for joint action in local public affairs.
4. By formulating in cooperation with the other societies a code of procedure and ethics to guide local councils.
5. By codifying successful methods of cooperation or contact between local councils and local governing bodies and assisting in establishing such contacts.

In summation, the solution of the problem of "establishing a high professional standing of engineers in civic and other affairs," may be along either or both of two lines:

1. Establishment of state and local engineering councils by joint action of the national engineering societies.
2. Establishing "an inner nucleus of highly qualified men whose professional standing and standards the public cannot possibly mistake" by some method and process of "certification of engineers by our major engineering societies."

Should the second plan ultimately be adopted, the various engineering councils might well be made up exclusively of "certified" engineers. The councils themselves, in all probability, still would be necessary, however. As an immediate step toward the desired end the formation of such councils composed of engineers of recognized high professional standing need not wait for the certification plan to be adopted.

Editor's Note: Correspondence is invited pertaining to any phase of the important subjects touched upon by Mr. Johnson. Every engineer all too soon will find himself the object and subject of inevitable legislation. For the greatest good of all concerned each individual should exert himself in cooperation with his national society to effect the necessary guidance and control of the situation.

Series Resistance To Increase Stability

As a possible method of increasing the transient stability limits of a long transmission system the author discusses the effects of inserting series resistances into the generator circuits to load the machines during fault conditions and thus retard subsequent overswings.

By
R. C. BERGVALL
Associate A. I. E. E.
Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

DEMANDS FOR CONTINUITY of power delivery from large electric stations which depend upon long transmission lines have expedited the development of high-speed circuit breakers and relays. Modern equipment will clear a fault with sequential breaker operation in from 8 to 16 cycles, depending upon the proximity of the fault to one end of the line. Because of the relatively low stored-energy-per-kilowatt factor of hydroelectric units and some steam units, even this short time, however, will not prevent loss of synchronism in many cases.

In this discussion consideration is given to the effects that may be achieved by inserting a relatively high series resistance into the generator circuit upon the advent of a short circuit. As an example for descriptive purposes, consider a short circuit to occur very close to [1] on the line [1]-[2] as shown in Fig. 1. The proposed series resistance normally would be short-circuited by circuit breaker [3]. A normal 60-cycle system is assumed; impedances as given on the diagram are based upon generator rating (kw.) and represent typical proportions. To assure that the ratio of resistance percentage to generator rating remains unchanged regardless of the number of machines in service, it is considered that resistances should be connected as shown in Fig. 2.

Upon the occurrence of a three-phase short circuit near circuit breaker [1] the generator electrical output will be decreased instantly from 100 per cent to 12 per cent of rating as a result of the low power factor in the fault-current circuit. The prime mover will continue

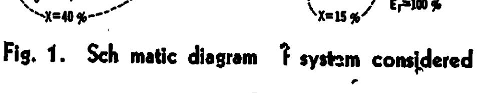

Fig. 1. Schematic diagram of system considered

From "Series Resistance Method of Increasing Transient Stability Limit," (No. 31-39) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

to apply 100 per cent torque and the difference of 88 per cent torque will accelerate the rotor. Circuit breaker [3] can be opened in from 5 to 6 cycles to insert the series resistance, and the resulting power loss will increase the generator electrical output from 12 per cent to 105 per cent until circuit breaker [1] opens after 8 cycles. A similar action takes place during the interval from 8 to 16 cycles when the fault is entirely removed from the system by the opening of circuit breaker [2]. The series resistance limits the rotor acceleration to about the same amount as would obtain if the fault were entirely removed in 5 or 6 cycles instead of in 16 cycles. This indicates the possible beneficial effects of loading the generators by inserting series resistance in the circuit during the fault period. After the fault has been cleared, the added series resistance component even though it increases the total circuit impedance exerts a substantial stabilizing influence because the stored energy of the hydro generators is less than that of the load center.

This action is shown in Figs. 3-6. Fig. 4 shows that the series resistance increases the maximum possible generator output from 147 per cent to 188 per cent of rated kilowatts. This is done at the expense of decreasing the maximum received power from 140 per cent to 92 per cent due to the loss in the series resistance. Figs. 5 and 6 show the corresponding power-angle diagrams. The shaded area in Fig. 5 shows the additional retardation area made available by the series resistance for reducing the overswing of the hydro unit. This large retarding force, acting only on the relatively low inertia of the hydro units, permits them to reach the position E_s'' (Fig. 3) instead of the position E_s' 18 cycles after a given fault, making the large gain of a_1 deg. The decreased power delivered to the load center is shown by Fig. 6, but due to the high inertia there as compared to the hydro generators a retardation of only a_2 deg. occurs. At the end of 18 cycles the total angular displacement has been decreased $a_1 - a_2$ deg. as a direct result of the insertion of 30 per cent series resistance in the generator neutral leads.

The series resistance, therefore, is beneficial in maintaining stability, both during and after a fault. Even if it is left in the circuit for a considerable time after fault clearance, the only effect will be a decrease in system frequency resulting from the added resistance loss; synchronism will be maintained.

CALCULATIONS CHECKED BY TEST

For the purpose of checking the methods of calculation used a shop test set-up of proportions similar to the hydroelectric transmission system of Fig. 1 was made. The hydro station was represented by a 100-kva. synchronous motor-generator set with the d-c. end acting as a prime mover. Sufficient external resistance was used in series with the motor armature to give it approximately constant-torque characteristics over a sufficient range of speed. The tests showed that for the same fault and time of circuit breaker operation, more than 50 per cent additional power could be delivered through the use of the series resistance without loss of synchronism.

For a system where the synchronous equipment at

the load-end is smaller in proportion to the hydro station than usually is the case, angular oscillations obtained from a point-by-point calculation with the help of an a-c. calculating board are shown in Fig. 7. There the dotted line indicates the rapidity with which the hydro generators go out of synchronism as compared to the characteristics of the synchronous machines at the load-end, if no series resistance is inserted. The full lines show the angular oscillation with 30 per cent series resistance inserted in the circuit during the period from 6 to 25 cycles following the fault. It is evident that synchronism will be maintained, because the angular deviation has been restored to about normal within 60 cycles and the system will stabilize itself after a few oscillations. The downward slope of the curve indicates that the system frequency has decreased slightly as the result of losses occurring while the series resistance was in the circuit. The slight decrease in frequency, however, is of no consequence so long as synchronism is maintained.

The magnitude of the series resistance can be varied over a wide range with practically the same results; in any event it should be inserted as soon as possible after the fault occurs. The length of time that it is left in the circuit will depend upon the individual system under consideration. The physical size of the resistor is approximately the same as that of a corresponding neutral resistor that would be used with a generator of the rating under consideration.

CONCLUSION

As indicated, it is believed that by inserting series resistance in the circuit for a short time, synchronism can be maintained readily on a hydro system of normal proportions and for any type of fault, with the speeds of circuit breaker and relay operation now available. The cost of the series resistance and its circuit breaker in general will be less than the combination of other measures that have been used and considered in the past. Unlike most of the other measures for improving stability, the resistor installation can be deferred until operating experience indicates that the added expenditure to maintain service is justified.

Calculations for Inclined Catenary

A method is outlined whereby the vertical and horizontal projections of contact-wire hangers are computed separately and the hanger lengths in turn obtained from these. The method postulates a smooth horizontal curve of contact wire, and can be used for both regular and irregular curves.

By
B. M. PICKENS
Associate A. I. E. E.
Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

INCLINED CATENARY on curves of railway overhead contact systems is used now quite generally in the United States on systems having a single contact wire, whether simple or compound catenary. An analysis of some of the problems in the design of inclined catenary is presented here outlining a fairly simple and direct method of solving them.

Design of inclined catenary for curves is not so simple as the design of tangent catenary. On regular curves of uniform span length the hangers on each different degree of curve will have different lengths and angles, but standard hangers can easily be calculated for each different degree. On transitions from tangent to regular curves or on sections of track where the degree of curve is continually varying, a separate set of hangers must be calculated for each span.

Forces acting in the catenary system are analyzed by considering separately the vertical and horizontal projections of the wires and hangers. For a horizontal-contact wire if the vertical projection of the shortest

---

From "Inclined-Catenary Calculations,"[*] (No. 31-27) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

curve hanger is made equal to the length of the shortest tangent hanger, the vertical projection of the inclined catenary will be the same as the vertical projection of the tangent catenary for a span of the same length. Consequently, all vertical dimensions can be calculated as if dealing with tangent construction.

Horizontal dimensions can be found when the curve of the contact wire with reference to an axis between it and the messenger projection is determined (see Fig. 1). The general relationship between any three adjacent contact-wire ordinates, which determines the shape the contact wire must assume in order to be horizontal is given by the following formula:

$$t_{n-1} = t_n\,[\,2 + c/(1 + x^2/c_1)\,] - t_{n-1}$$

where $c = s\,w\,(M + T)/v_0\,T\,M$

$c_1 = 2\,v_0\,M/W$

M = messenger tension in lb.

T = contact-wire tension in lb.

W = weight of system in lb. per ft.

s = distance between hangers in ft.

w = weight of s ft. of contact wire in lb.

v_0 = vertical projection of shortest hanger in ft.

x = distance of nth hanger from center of span in ft., measured along axis.

Other relations are as shown in Fig. 2.

From this equation general shape curves can be drawn for any given catenary system. These are called the *U* and the *S* curves and are shown in Fig. 3. The *U* curve corresponds to the shape the contact wire will take on a constant radius track curve. The *S* curve corresponds to the shape the contact wire will assume on a reverse curve where the reversal occurs at the center of the span. Shapes of the contact wire for curves between these two extreme types can be found by adding together the two curves. The specific shape the wire will take on any given curve is determined by finding the correct multiplier for the *U* and *S* curves; thus a general equation may be written,

$$t = a\,U + b\,S$$

where a and b are the respective multipliers of U and S curves to satisfy the conditions of the particular curve in hand. In the case of uniform curves where the span lengths do not change, b becomes zero and a is determined by the length of span, the radius of track curve and the slope of the U curve at the support.

The contact wire must take a smooth continuous curve from span to span. Mathematically this means that the contact wire curves for two adjacent spans must have a common tangent at the support. This is one of the conditions used in the solution of the constants for the general equation of the contact-wire curve. These constants are obtained by solving simultaneously the group of equations which can be written for two adjacent spans. The data regarding the track characteristics are obtained from field measurements or track plans. In order to obtain a solution it is necessary to approximate a value for the contact wire ordinate at the third support in the two spans but it can be done by treating the section of track, at the third support, as a uniform curve. The value used will be checked automatically by the calculations for the next span. When the constants for the general equation are obtained the values for the contact wire ordinates at the various hanger locations and supports can be calculated and all the values for hanger lengths, angles and support locations are known.

The contact-wire curve may not assume the same shape as the track curve. On uniform curves it can be given practically the same shape as the track curve but this imposes certain limitations on the design that are not always desirable. The average unit stresses in the supporting and supported wires must be the same for materials of the same specific gravity. Where this design condition is not followed the contact-wire curve will depart somewhat from the track curve and must be allowed for in the design.

Catenary Construction for the Cleveland Terminal

Design and construction details involved in the electrification of 59 track miles in connection with a major union terminal development are outlined.

By
N. F. CLEMENT — Associate A. I. E. E. — Formerly with The Cleveland Union Term. Co.
E. E. RICHARDS — Non-member — The Cleveland Union Terminals Company

HEAVY CURRENTS and low overhead clearances were the principal factors governing the design of the catenary system of the Cleveland Union Terminal at Cleveland, Ohio, where twenty 200-ton electric locomotives are in active service, each capable of pulling a fifteen-car pullman train up the maximum grade. Throughout the electrified system were many overhead bridges having relatively low clearance, and most of the station area is covered by buildings with an overhead clearance of but 17.5 ft.

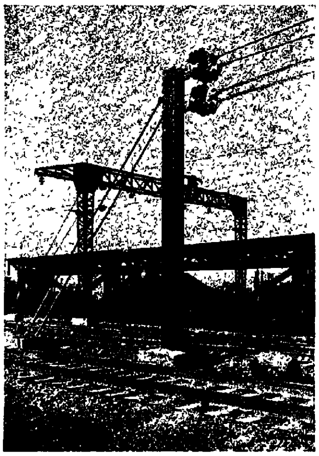
Two main tracks were electrified for a distance of 11 mi. east of the public square, where the station is located, and about 6 mi. west of the same point. Including crossovers and yard tracks, the total electrified mileage is about 59 mi. Two substations, each approximately midway between an end of the electrification and the Cleveland station, supply the catenary system with 3,000 volts direct current.

CATENARY CONSTRUCTION

The tangent chord type of construction is used, because the weighty system necessary for the carrying of heavy currents does not lend itself readily to the inclined type of construction. Except through the Cleveland station, the construction over the two main tracks consists of a primary messenger supporting by hangers a secondary or auxiliary messenger to which are clipped two 4/0 grooved bronze contact wires placed side by side. The primary messenger has a 19-wire core of high-strength bronze, and a 16-wire outer layer of copper, the total conductivity being equal to 350,000 cir. mils of copper. The auxiliary messenger is 4/0, 19-wire hard-drawn copper, and the hangers supporting it are of No. 1 hard-drawn copper wire.

For yards and crossovers the auxiliary messenger is dispensed with. The two 4/0 grooved bronze contact wires are placed one above the other, the upper one suspended by means of hangers from a 5/8-in. bronze messenger, and in turn supporting the lower one by clips.

In the station area, tandem contact wires only are used. These are 4/0 grooved bronze wires, one above the other as in yard construction, suspended in approximately 70-ft. spans. This construction was necessary to keep the line down to around 17 ft. above the rail. The main messenger and auxiliary are dead-ended on both sides of the station, and one 150,000-cir. mil cable for each main line track is carried through a duct from one dead end to the other.



Dead-end construction for two main-line catenaries. Yoke assemblies are used for the auxiliary messenger and contact wires, similar to those for the main messenger

Each main line catenary is divided electrically into five sections by four air-gaps or isolated sections. Separate feeders are run to the isolated sections, two sections being on the east and two on the west of the Cleveland station.

The maximum span on tangent track was fixed at 300 ft., giving a sag of approximately 5 ft. at 60 deg. fahr. with the assumed weights. With a 21-in. suspension assembly, a 6-in. center hanger, and an assumed 3-in. distance between the auxiliary messenger and the contact wires, it was found that structures about 7 ft. 6 in. higher than the contact wires were required. Due to the great number of low-clearance overhead street bridges it was decided to use the rather low normal contact wire height of 18 ft. 6 in. at 60 deg. fahr., thus giving a structure height of 26 ft. for a 300-ft. span.

For spacing structures on curves, charts similar to those used by the designers of the Illinois Central catenary system were made up. It was assumed that on curves the contact wire would not be allowed to be more than 12 in. from the inclined center line of the

---

From "Design of Catenary System for Cleveland Union Terminal," (No. 31-31) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

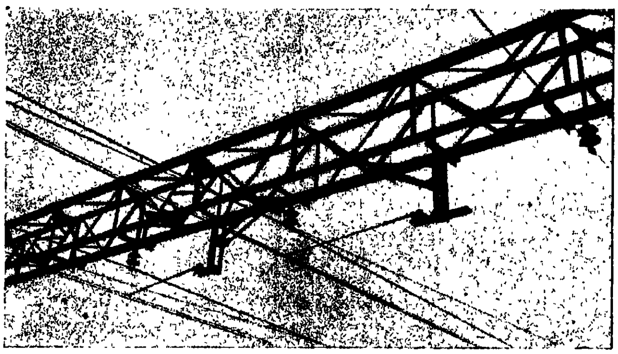
track, either at the center line of the span or at the ends, thus giving a maximum allowable middle ordinate of 2 ft. In laying out the plans, celluloid curves representing the messenger wires with dead load at 0 deg., at 60 deg., and at 120 deg. fahr. were made and used on profile paper to draw in the messenger above the contact wires. The height of all structures then could be read directly from the profile.

When approaching low-clearance overhead street bridges the line was gradually lowered so that the messenger took its natural curve under the bridge, avoiding upthrust on the suspension insulators attached to the bridge. The natural curve used in these cases was the 0-deg. curve.

The various structure heights obtained from the profile were grouped in steps varying by 6 in.; foundation depths also were varied by 6-in. steps. This expediency permitted the structures to be designed in groups varying in height by 1 ft.

SAG AND TENSION CALCULATIONS

Parabolic formulas were used in the sag and tension calculations, because the parabola of the simple curves was considered to give the closest approximation to the true curve of the messenger. The sag and tension chart was drawn for a 300-ft. span, modified slightly from the A. E. R. E. A. chart in that the load lines were made curved instead of straight, thus allowing the use of a uniform scale for sag. The decision to use a non-corrosive messenger was found to introduce large vertical movement that could not be avoided. The messenger finally selected had a sag of 46.5 in. at 0 deg., 58.5 in. at 60 deg., and 73 in. at 120 deg. fahr. for a 300-ft. span.



Steady arms are used on tangent track to brace the auxiliary messenger and contact wires

The equivalent span, using Idail's formula, was found to be 260 ft. for the main line and to range from 120 to 280 ft. for the yard lines. As it was impossible to string every yard line on a different tension basis, the yard-line values were divided into two sets, those having equivalent span lengths up to 200 ft. using 160 ft., and from 200 ft. up using 240 ft. The equivalent span for the auxiliary messenger and contact wires was 20 ft.

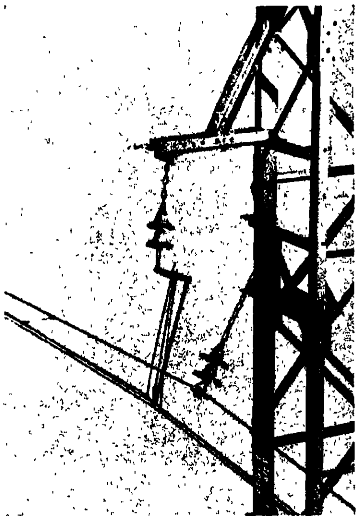
From the charts based on equivalent span lengths, curves of tension against temperature were plotted. These stringing charts were made up for all wires. The main messenger chart also had curves of sag against temperature, so that the messenger could be strung by either the sag-stick or the dynamometer method.

The system of spacing hangers which was worked out is simple, looks well, and was easy to lay out in the field. The end hanger is always 10 ft. from the suspension clamp; then, working toward the center, there are as many 20-ft. spaces on each side of the center as will go in evenly. Any space left in the center of the span is divided into from one to three equal spaces. An instrument designed to roll along the messenger was used to mark the spaces so that tapes were not needed. Hanger lengths were obtained to the nearest half-inch by a graphical method.

STRUCTURAL DETAILS

For dead-ending the main messenger the yoke set used comprises two parallel strings, each consisting of three 10-in. 18,000-lb. insulators. The auxiliary messenger and the two contact wires are dead-ended with a similar assembly giving a symmetrical appearance and equivalent electrical strength. The dead-end assembly for the yard messenger and the two contact wires consists of two 12-in. 24,000-lb. insulators in series.

At all structures on tangent track a steadyarm is used to brace the auxiliary messenger wire and both contact wires. At those structures which were followed immediately by a curve or spiral, a pull-off attachment added to the steadyarm was necessary because of the low auxiliary-messenger tension. If the contact wires are not held where slight changes in alinement occur, such as at the beginning of a spiral, they pull toward the inside of the curve enough to permit the auxiliary



The type of pull-off construction used in the main lines. Much time was saved in construction by the use of chain supports

messenger to gather slack from both sides of the steadyarm resulting in a large horizontal sag in the messenger at the point where it is clamped by the steady arm. On the sharper curves regular pull-offs without steady arms were used.

An interesting feature of this installation is the use of $\frac{3}{8}$-in. galvanized chains instead of cable and Crosby clips to hold the pull-off. Much time was saved in erection, and it is expected that by this scheme much more will be saved in maintenance. The chain link is dropped into a slot in the vertical leg of an angle, which in turn is bolted to the column or bracket.

The steadyarms were attached to the structures so as to be approximately horizontal at 0 deg. fahr., and the pull-offs, so that their slope at 0 deg. would be parallel to a line across the top of the track rails. Nearly all the brackets, angles, etc., for supporting the catenary and holding it in the correct horizontal relation to the track are fastened to the structures with bolts to facilitate shifting them to conform with changes in track alinement. The steadyarm and pull-off attachments are designed to permit a vertical adjustment of 1 ft.

After the erection was completed a final alinement of the overhead system was made, using the pantagraph of a trolley as a guide. The pantagraph was marked with white lines 1 ft. on each side of the center, and the catenary was so adjusted that the contact wires were kept within these lines at all points. It was found that very little realinement was needed. No major operating troubles have developed during the several months that this catenary system has been in service; and it has proved very satisfactory.

Telephone Toll Cable Extended

Completion of the longest telephone toll cable west of the Mississippi gives San Francisco and Los Angeles a 275-circuit all-cable communication channel, the equivalent of three of the latest-type 60-wire open leads completely equipped with carrier systems. The project cost ten million dollars, involved some heavy construction problems, and provided an important step toward an ultimate all-cable transcontinental system.

IN THE TERRITORY of the Pacific Telephone and Telegraph Company there are four major centers of population: the triangle formed by Portland, Seattle, and Spokane on the north; the San Francisco Bay district in the center; the Los Angeles-San Diego area on the south; and the Sacramento-San Joaquin Valley area in the central part of California. Originally, telephone service was established between these centers by the use of relatively small open-wire leads. As demands for intercity service increased, it became necessary to concentrate more plant in the vicinity of these populous areas and also to enlarge the connecting routes.

About 1920 it became apparent that in several cases future telephone facilities would have to be provided by means of cable. Hence a program was entered into initially involving cable extensions from Los Angeles to Long Beach, Anaheim, and Santa Monica; a cable between San Francisco and San Jose; and between Seattle and Tacoma.

Prior to the installation of the San Francisco-Los Angeles toll cable there were two main open-wire toll routes (Fig. 1) between these points, one known as the coast route and the other as the inland route. These leads were of the phantomed type and were transposed for the use of carrier telephone systems. In addition to the voice circuits supplied by these facilities, they provided for miscellaneous services, such as telegraph, radio program supply, and picture transmission. Annual growth in the telephone circuits was such that after 1930 it was economically impossible to care for the requirements by additions to these leads.

Various plans for relief were studied, resulting in 1926 in the adoption of a program for the installation of a toll cable along the inland route. This cable, now completed, is the longest (412 mi.) west of the Mississippi; with buildings, and associated equipment, it represents an investment of approximately $10,000,000. It was placed in service September 2, 1930, and provides approximately 275 circuits, about the equivalent of three of the latest type six-arm pole leads fully equipped with carrier telephone systems. Conductors suitable

for both long- and short-haul circuits are included in the cable (Fig. 2) and means are available for furnishing all special services previously mentioned.

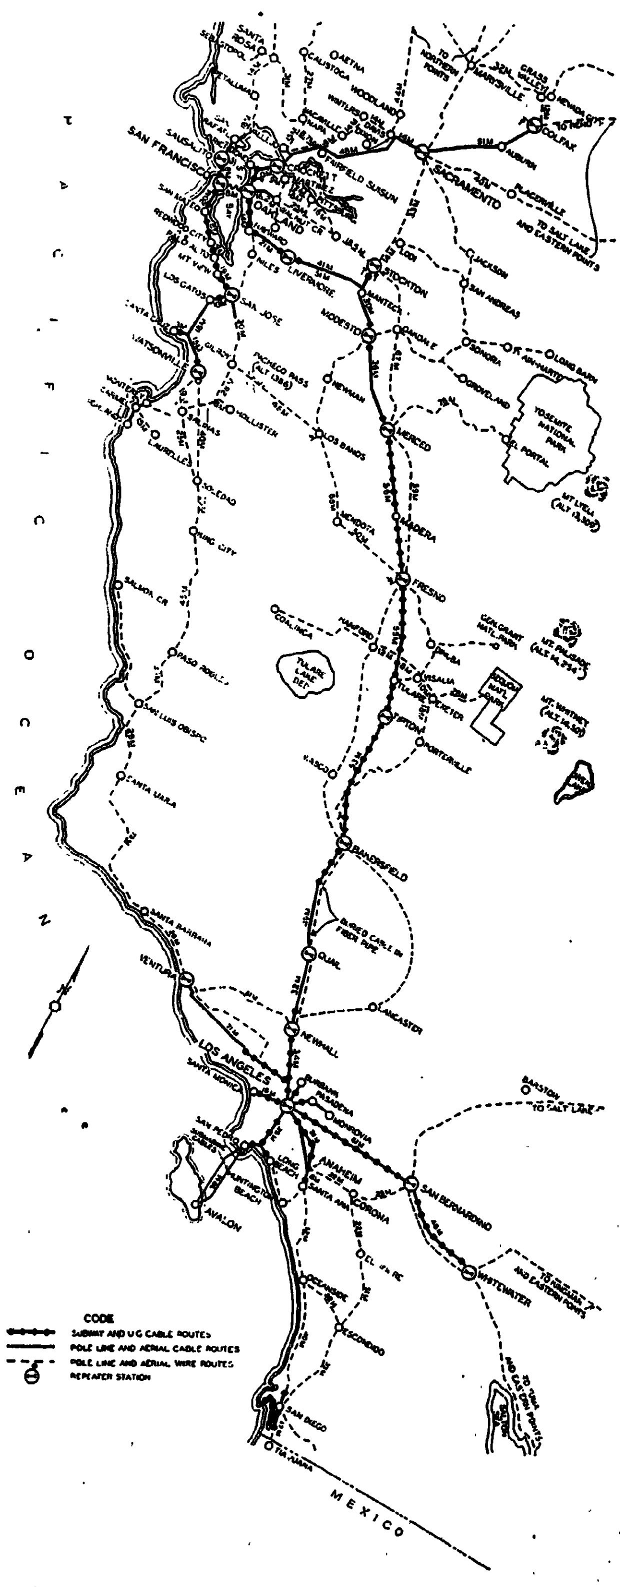

Fig. 1. Map showing open-wire and cable routes between San Francisco and Los Angeles

The cable selected was a full-size Bell System standard weighing approximately 7.6 lb. per ft. and having a lead-antimony sheath 0.125 in. thick. In this cable spirally wrapped paper-insulated wires are twisted together to form pairs which in turn are twisted together in groups of two pairs to form "quads," the unit dealt with when it is desired to use phantomed operation to enable three voice paths to be derived from two pairs of wires.

To decrease the attenuation or transmission loss, loading coils in cast iron or welded steel cases are associated with each pair at regular intervals throughout the route. Three Bell Standard loading systems were selected. One (known as H-44-25) is used for long-haul service and consists of 44-mh. coils on sides and 24-mh. coils on phantoms, these coils being placed on *H* or 6,000-ft. spacings. This loading is placed on 19-gage wire and the facilities so obtained are operated on a four-wire basis (*i. e.*, separate paths for the two directions of transmission). Having separate paths for transmitting in two directions makes greater amplification possible at repeater offices and greater freedom from difficulties arising from electrical reflection or echoes. However, with the longer four-wire circuits it still is desirable to install equipment which eliminates the echo return path. Hence echo suppressors are installed at Fresno.

The next loading system, in order of decreasing excellence, consists of the same weight of coils with the same spacing on 16-gage wire, the actual loading differing only in slight adjustments for cross-talk. These
